The CHAIRMAN, in reply, said he had been asked to state whether the Company had or not a business which the directors believed to be becoming a paying one. He thought the best answer he could make to the question was that the directors were large shareholders—that they had between them 1,250 shares, on which they would have to pay the call which they had made. He said without fear of contradiction that they had arrived at the time when they had not to do any more unprofitable work in the colonies, and that their work in the future was going to be profitable. The prospectus set ont the sums that were to be paid for the patent rights to be acquired. Sir Julius Vogel was absent for ten months on the affairs of the Company, and he received ten guineas a day—a rate of remuneration which he (the chairman) did not consider too high for the work undertaken. The directors were disappointed that he was not able to make sales of the patents, but people could not do impossibilities. There was no litigation whatever between the Company and the firm of Latimer Clark, Muirhead, and Company. He did not agree that directors should be asked to work for nothing, though he knew that was nowadays a very common expectation. They had given up half their fees.

The SECRETARY gave the details of the expenses in London and the colonies, and

The CHAIRMAN stated that a calculation had been made on the present contract prices, showing that if they turned over £25,000 a year in plant, every possible expense would be covered. A suggestion had been made that the directors should appoint a committee to assist them, but he had informed them that before the report was printed the directors had consulted with some of the principal shareholders. It occurred to him that instead of appointing a committee the best course would be to ask the shareholders to increase the number of the directors by appointing two gentlemen not of the nomination of the directors. If they had a thorn in their side it was the Sellon-Volckmar accumulator, which was brought to light just before the birth of the Company. He then detailed the circumstances in which they acquired this patent, and stated that an action had been instituted for the recovery of the £5,000 paid, their contention being that they had got no consideration for it. At first their action had failed, but they had been advised to appeal, and they had done so. The amalgamation with the Company in Victoria would be submitted to the shareholders before its final ratification. It was difficult to say whether they were at present covering their expenses, for they had not seen the results of the last five months' working. The tota lexpenditure last year was £14,000, but of that amount £7,000 was for "dead work," and he did not think that the actual expenditure, £7,000, was so very extraordinary for such a Company as theirs.

The SECRETARY, in reply to a question, thought that the expenditure since the 30th of June had been at the same rate of £7,000 a year—possibly, indeed, they had spent since then £5,000, including the cost of some additional installations.

The CHAIRMAN: But for which we have to be paid.

The SECRETARY observed that the amount of expenditure he had mentioned was on the assumption that they would get nothing back, but they were bound to get a large amount back.

The CHAIRMAN, in further reply, stated that the plant they had put up had given perfect satisfaction. They would put up no more plant unless it were ordered.

The motion was then unanimously adopted, the four gentlemen who at first dissented withdrawing their opposition. It was subsequently decided to ask Mr. Robert Hammond and Mr. Pankard to join the Board; and the auditors, Messrs. Deloitte, Dever, Griffiths, and Co. were reappointed.

The meeting then closed in the usual manner.

## THE INDIAN AND ORIENTAL ELECTRICAL STORAGE AND WORKS COMPANY (LIMITED).

An adjourned ordinary general meeting of this Company was held at the City Terminus Hotel, Cannon-street, on Wednesday, the 16th inst., under the presidency of Mr. Ernest Noel, M.P.

The SECRETARY (Mr. H. Cleland Heywood) read the notice calling the meeting. The report and statement of accounts were taken as read.

The CHAIRMAN: Gentlemen, I shall not enter upon a detailed criticism of the report that was made by the committee of shareholders. It might have been that I thought it my duty to do so, but I certainly do not feel it to be so now, because since that report was issued fresh arrangements have been made with the parent company, and those arrangements have proved completely satisfactory to the committee, or very nearly so, and therefore I do not see that it would be of any public advantage or any use to you that I should occupy your time by making any detailed remarks on that report. Of course I cannot say that I agree with all that is contained in the report. But, as you are aware, at the first general meeting I informed the shareholders that the Board had been able to get what we consider some very considerable concessions from the parent company as regards the shares that they held. I will just in a very few words recapitulate what was our position and what will be our position, I trust, at the close of these meetings. It was proposed first that the 10,000 shares that we had to allot to the parent company should be deferred shares as far as dividend was concerned. It was further agreed that they should grant to us, free of all cost, a patent of M. Philippart, which, we believe, as far as we can judge, obviates many of the difficulties that we found in the practical working of these batteries in India. That is a question that the future alone can decide—that is to say, whether it is of the value it is supposed to be or whether it is not. At all events it comes to us without payment. The committee of shareholders, as you are aware, were not at all satisfied with those concessions on the part of the parent company, and you also had a letter from the parent company in which, at that period, they declined to do anything further. At the same time I am bound to say that the directors of the parent company have shown, as far as I have been concerned in negotiating with them, the greatest desire to meet any reasonable request of this Company. A letter was drafted and sent to them asking them whether they could not proceed further in the line of concession (but previous to that letter we had an interview with the Board), and then a letter was written, which letter contained a proposal that the shares of the Company should be reduced to £3 10s., that is by 30s. I must point out to you that the result of that is that their shares which were £5 (10,000 of them at £5, which was £50,000) will now become worth only £35,000, and that in case of the liquidation of the Company (which I trust will never take place, and I still have some hopes that there is a future for these batteries in India), if we wind up the result of that concession is that we have to pay to them £15,000 less than we should have had to pay, because, without the slightest doubt, we should have had to pay, in the event of winding-up, £30,000 to the parent company as the difference of the amount between their shares as fully paid, and ours, which were only £2 paid. But there is something more in this concession than that, inasmuch as the concession that they are ready to make to us not only gives us, as I think, a gift of what they had a legal right to, namely, something approaching £15,000, but it also gives to us this advantage, that the liability on your shares will be reduced to that amount all round quite independent of what we owe to the parent company, and, as many of the shareholders are not sanguine as to the future of electric lighting, &c., that is an advantage which every one must perceive. I would also add that, supposing we find eventually that these batteries are, as many people still think, destined to play a great part in the electrical world, especially as regards electrical tramways, if more money were required for the working of this Company in India, it could be raised by a fresh issue of capital, so that while we are reducing our capital now we shall in nowise endanger the future of this Company should it turn out to be, as some of us hope from the patent that we shall secure after this meeting, a really valuable property. There is only one portion of the report which I feel bound to make a few remarks on, because I think it injuriously affects the interests of the shareholders of this Company. It is a portion of the report which, if allowed to remain uncontradicted, would, I think, seriously damage your property, and therefore I am bound to advert to it. It relates to a statement made in the report about what Mr. Littlewood communicated to the committee. I must first say that Mr. Littlewood has no knowledge of electricity whatever, and therefore his statements can only be taken as regards the facts of the working of these batteries in India. It is perfectly true that those batteries had not succeeded in India, but Mr. Littlewood did not point out to the committee the reason why those batteries failed. If he had pointed out that the difficulties were not inherent in the batteries themselves, but connected with their mechanical arrangements—only adjuncts to the batteries—a very different reason as to their failure would have been forthcoming. I will give you one or two instances. It was said the boxes were found utterly inefficient. Has that anything to do with the inherent value of the batteries? Again, "there were a large number of plates sent out, and we have reason to believe they were overcharged when they went." Had that anything to do with the inherent value of the batteries? I will give you another. "The whole of the underground system in Bombay by which they were utilised was such that I fancy no system could have succeeded." Had that anything to do with the batteries? Again, "I should mention that those who had to deal with them had not the proper system of charging those batteries." Had that anything to do with the inherent value of these instruments? That is the only correction I wish to make in this respect, which I feel bound to make in the interests of the shareholders of this Company—that the causes which led to the failure of these batteries in India (and there is no doubt that they did fail) were causes which had nothing whatever to do necessarily with the inherent value of the batteries themselves, but were causes which I may sum up in one word—they were mechanical difficulties which may or may not be overcome. The chairman here read the correspondence that took place between the secretary and the parent company on the subject of the concessions, and concluded by moving "that the report of the directors and statement of accounts to 30th November, submitted to this meeting, be and they are hereby adopted."

Mr. BEDFORD seconded the motion, which was unanimously agreed to.

The CHAIRMAN next moved, and a shareholder seconded, the reappointment of Messrs. Deloitte, Dever, and Co., as auditors of the Company, which was agreed to.

The CHAIRMAN moved "That the shareholders do and hereby authorise the directors to pay out of the moneys of the Company the legal expenses of the committee."

A SHAREHOLDER having seconded the motion, it was carried *nem con.*

Mr. BEDFORD then said: The shareholders will remember that the committee were very desirous of obtaining a postponement of the meeting for three weeks, and after considerable discussion it was found that we could not possibly be granted more than two weeks in order to carry through the resolution proposed at the extraordinary general meeting. We desired that length of time because we were fully impressed with the important duties that we had to discharge, and having a good deal to look into we did not want to hurry through the work and pass anything that might be imperfect. At the same time we felt if we had that time at our disposal we should perhaps have an opportunity of meeting again the parent company, and perhaps arrive at some compromise which

Digitized by Google

would enable us to present a report to the shareholders which would put aside all difficulties, and cause our Company to go on harmoniously. As a matter of fact we did have some check from the manager of the Company about certain proposals, but time was running on, and it became imperative to present our report. The negotiations were in such a state that there was a probability of their falling entirely through, and we were bound to make the report that we submitted. That is all I shall say about the report. Within thirty-six hours after it had been in the hands of the shareholders we received an intimation that the parent company were prepared to make certain concessions, and they would very much like us to consider and pass our opinion upon them. Those concessions you have already heard from the chairman, and I need not go over them except to state that they appeared to us, after due consultation and consideration, to be all that we could reasonably ask, and in the exercise of our judgment we came to the decision that we should support them, and if needful in their support use the proxies which had been entrusted to us for the purpose of doing that which was best for the interests of the shareholders I hear, some hopes for the Company in the future, and to realise those hopes we expect to pursue that policy which the chairman has indicated. We shall husband our resources, cut down our expenses to the very lowest possible point, not enter into any experiments, and spend no money beyond that which is needful for keeping the Company alive, and then, when the time comes—if ever it does come—that we can see our way clear to enter upon this business with some solid ground for believing we shall succeed, I do not at all doubt that the shareholders will be very willing to respond to any future call, and I am sure the chairman will give a pledge that he and the other directors will not make any call upon us before convening the shareholders, and explaining fully what that call may be for.

The CHAIRMAN assured the last speaker that it had always been and would continue to be the policy of the Board before entering upon any undertaking that would necessitate a further call to bring the shareholders together and take their opinion before any steps were taken towards it. He concluded by reminding the meeting that as there were two vacancies on the Board the directors would be glad to be reinforced by two of the shareholders who served on the committee. At present the directors received nothing for their trouble and time, but he for one would be quite willing to serve for some months longer to the best of his ability, and then he would feel it necessary to come to some fresh understanding as regarded the question of remuneration.

A SHAREHOLDER hoped that any additions to the Board would be selected from the original shareholders.

Another SHAREHOLDER objected to that on the ground that the most competent gentlemen might not thus be obtained.

Mr BEDFORD suggested that the matter be left in the hands of the directors themselves, a suggestion which seemed to meet with the approval of the general body of the shareholders present.

The meeting was then made extraordinary. The notice calling it having been read by the SECRETARY,

The CHAIRMAN moved: "That the directors be, and they are hereby authorised to accept the surrender by the Electrical Power Storage Company of the 5,000 fully-paid shares, numbered 30,001 to 35,000, both inclusive, now held by them, and to issue in lieu thereof 5,000 deferred shares, such as hereinafter mentioned. And that of the 80,000 shares forming the original nominal capital of the Company, 10,000 shares shall be deferred shares, and the remaining 70,000 shares shall be ordinary shares, and that the deferred shares shall not be entitled to dividend in any year until a dividend of five per cent. for that year and every previous year, as from the 31st December, 1883 (or from the issue of the ordinary shares as to any issued subsequent to that date), shall have been earned upon the ordinary shares, but when such dividend of five per cent. shall be earned as aforesaid, the said 10,000 deferred shares shall be entitled to receive out of remaining profits a five per cent. dividend, and after provision for same, to participate for dividend in the residue of the profits equally with the ordinary shares, upon the full amount credited as paid upon the said deferred shares."

Major STRUTT seconded the motion, which was unanimously carried.

Votes of thanks were subsequently passed to the committee and to the chairman, and the proceedings terminated.

## WEST COAST OF AMERICA TELEGRAPH COMPANY (LIMITED).

Anticipating the annual report and balance-sheet, with a view to the distribution amongst the shareholders of some portion of the cash profits of the Company now lying at the bankers of the Company in London, the directors have the pleasure to announce that, according to cable advices, the gross earnings of the Company for the year ending the 31st December last amount to an estimated sum of £58,000 against the sum of £38,891 0s. 4d. for the corresponding period of the previous year, or an increase of somewhere about £19,000. It is of course impossible to give the exact working expenses for the year, but the directors calculate that there will be no large or appreciable increase upon the actual expenditure of the previous year, which, according to the balance-sheet, and including the expenditure in London, amounted to a total of £19,240 11s. 9d. To this sum has to be added the interest on the Company's fixed debentures, which has been paid as usual, viz., £12,000, making the total estimated expenditure, with the debenture interest added, into a sum of £31,240 11s. 9d., or, in rough figures, and making allowance for an increase in expenditure for the past year, say a sum of £32,000, which amount, deducted from the estimated gross earnings, £58,000, will leave a balance of net profit on the year's working of a sum of about £26,000. In view of the result of the year's working—a result which the directors regard as satisfactory—and pending the settlement of balances with other companies, and the final adjustment and audit of accounts on the west coast and in London, the directors have this day declared, out of the profits for the year, a dividend at the rate of 4 per cent., or 8s. per share on the ordinary shares of the Company. This dividend will absorb a sum of £12,000—leaving the balance to be dealt with hereafter, or on the issue of the annual report and balance-sheet. To cope with the increase of business, and in order to give greater efficiency to the Company's service, the staff on the coast has been augmented by sending out, since the last report was issued, some additional clerks. Any increase in expenditure involved in taking this step, which was alike judicious and unavoidable, will, however, be partly met by economies in other directions. As a matter of information the directors regret to state that the Company's claim is not yet arranged, but it has at length been placed prominently before the Chilian Government, and a satisfactory settlement is still hoped for. The Company's repairing steamer has been efficiently maintained, and the electrical condition of the Company's cables leaves nothing to be desired by the Board.

## WESTERN AND BRAZILIAN TELEGRAPH COMPANY (LIMITED).

Report of directors, to be presented at the eleventh ordinary general meeting of the Company:—The directors submit their report and the accounts of the Company for the year ended 30th September, 1883. The total earnings amount to £112,706 11s., a decrease of £2,463 5s. 11d. compared with last year, caused mainly by the interruption of the Brazilian Submarine Company's cable, referred to below. The working expenses for the year amount to £61,127 19s. 11d., as against £61,919 3s. 8d., a decrease of £791 3s. 9d. These expenses include £1,800 for depreciation of ss. "Norseman," an item which did not enter into last year's accounts. Since May last, the new steamer "Viking" has been in commission and has proved well adapted for the service, having effected some important repairs. Including the amount brought forward from last year, the balance to the credit of the net revenue account is £29,369 13s., out of which amount the Board has already paid an interim dividend at the rate of 2½ per cent. per annum for the half year to 31st March, amounting to £13,108 2s. 6d. It is now proposed to pay a further dividend (also free of income-tax) at the same rate to 30th September. This will absorb a further sum of £13,108 2s. 6d., leaving £3,153 8s. to be carried forward to next year. In consequence of the continued competition by the Brazilian Government, the Board has at length found it necessary to reduce the tariff over the cables of this Company to that of the Brazilian land lines. This reduction came into force on the 1st September last, and the preference accorded to the Company's lines by the public has produced satisfactory results. On the 22nd September the cable of the Brazilian Submarine Telegraph Company between St. Vincent and Pernambuco was interrupted. Communication was not restored until the 4th December. The duplication of its cables which the Brazilian Submarine Telegraph Company has decided to carry out will give to this Company increased security. The retiring directors are Sir Henry Drummond Wolff and Mr. D. H. Goodsall, who offer themselves for re-election. The auditor, Mr. Weise, retires, and is eligible for re-election.

## NOTES.

MORE EXHIBITIONS.—Antwerp wants to hold a Universal Exhibition within its walls during 1885.

BRAZILIAN SUBMARINE TELEGRAPH COMPANY.—The traffic receipts of this company for the week ended 18th inst. amounted to £3,510.

THE SUAKIM CABLE.—At the time of writing this cable has not been landed, owing, no doubt, to bad weather prevailing in the Red Sea.

ELECTRIC LIGHTING IN A HOSPITAL. The new hospital for cases of infectious diseases at Newcastle-upon-Tyne is to be lighted by means of Swan incandescent lamps.

ELECTRIC LIGHTING AT DEAL.—The electric light has been introduced into Deal by Messrs. Frost Brothers, of that town. They have been exhibiting both the arc and incandescent systems.

WEST INDIA AND PANAMA TELEGRAPH COMPANY.—The estimated traffic receipts of this company for the half month ended January 15 are £2,507, as compared with £2,096 in the corresponding period of 1883.

ELECTRIC LIGHTING AT LIMEHOUSE.—The Edinburgh Castle Mission Hall at Limehouse, E., has been fitted with the electric light by Messrs. Siemens Brothers. There are five arc lamps and 200 Swan lamps.

ONCE MORE.—The registered sunshine for the week ending Saturday last, as taken at the Royal Observatory, Greenwich, was *nil*. This is the third week within a month that *nil* has had to be written across the record.

THE SOCIETY OF TELEGRAPH ENGINEERS.—The next meeting will be held on Thursday, January 31st, at 8 p.m., when the following paper will be read:—"On a System of Electric Fire Alarms," illustrated by diagrams and apparatus, by Edward Bright, member.

APPOINTMENT.—We are informed that Messrs. William Denny Brothers, of the Leven Shipyard, Dumbarton, have appointed Mr. R. D. Smillie, M.S.T.E. and E., as their electrician. This firm intend to establish an electrical department in connection with their extensive shipbuilding works.

ELECTRIC LIGHTING AT LIVERPOOL.—The contract entered into between the Liverpool Corporation and the Lancashire Maxim-Weston Electric Company is nearly completed. The company contracted to light Castle, Lord, Church, Parker, and Elliot streets, the total lamps required amounting to twenty. Last week nearly all these lamps were going.

ACCIDENT TO AN ELECTRICIAN.—We regret to announce that Mr. John Brown, of Belfast, whose name is not unknown to our readers, met with an accident whilst experimenting at Trinity College, Dublin, a few days since. The bursting of a retort caused a fragment of glass to enter Mr. Brown's eye, with the result that he has had to have the eye removed.

SUBMARINE TELEGRAPH COMPANY.—It is notified that the accounts of the Submarine Telegraph Company for the half year ending December 31 last, submitted to the board, show a balance, subject to audit, which enables the directors, after adding 15 per cent. of the gross receipts to the reserve fund, to recommend a dividend at the rate of 15½ per cent. per annum.

ANOTHER PRIMARY BATTERY.—M. Delarochelle has patented a novel arrangement of elements in a primary battery, of which it is reported that 20 incandescent lamps (kind and candle-power not stated) can be fed for 30 to 40 hours with 48 elements coupled, eight in series. Experiments are being made with this battery at the Café Anglais, Boulevard des Italiens, Paris.

DISSOLUTION OF PARTNERSHIP.—We understand that the winding up of the Yorkshire Brush Company and Messrs. Ferranti, Thompson, and Ince (Limited) has brought about a dissolution of partnership between Messrs. Kingsland and Smith, of 1, East-parade, Leeds, their late agents, and that Mr. Wm. Kingsland will continue to carry on business at that address as an electrical engineer and contractor.

A CABLE TO LUNDY ISLAND.—It appears that a project is on foot amongst some merchants, underwriters, and others in Swansea, Cardiff, and Bristol to lay a cable from Lundy Island to the mainland, presumably that ships may call there for orders, &c. From a copy of a local paper that has been sent us it would seem that Newport is very much disgusted at not being asked to have a finger in this pie.

HONOURS FOR A TELEGRAPH ENGINEER.—The honorary title of "Officier de l'Instruction Publique" has been conferred by the French Government on Mr. E. W. Parsoné, engineer and general manager of the West Coast of America Telegraph Company, for the assistance and co-operation given by him to the French Commission during the determination of longitudes of the different ports on the west coast of South America.

LIGHTING BY PRIMARY BATTERIES.—On the occasion of Dr. Tyndall's recent lecture on "Rainbows" at the Royal Institution, Mr. Ross's primary battery was used to light the large library for an hour before the lecture and during the *conversazione* which followed. Sixteen incandescent lamps of 20 candle-power were attached to the two chandeliers suspended from the ceiling, and brilliantly lighted the whole of the large room.

SS. "JOHN PENDER."—The Eastern Company's ship "John Pender" is now alongside the Telegraph Construction and Maintenance Company's Works, at Greenwich, taking in stores and cable. The "John Pender" will replace the "Chiltern," engaged in laying the Suakim cable. The ship has been fitted up with new picking-up gear, designed by Messrs. Johnson and Phillips, and constructed by that firm for the Eastern Company.

MUIRHEAD'S DUPLEX SYSTEM FOR CABLES.—We are informed that Mr. Muirhead has entered into a contract with Messrs. J. W. Mackay and J. Gordon Bennett for the application of the Muirhead duplex system of telegraphy to the two Atlantic cables about to be laid for these gentlemen, concerning which some further information will be found in another note. This system is now at work on about 30,00 miles of cable, and has proved of great utility in facilitating traffic.

THE CADIZ-TENERIFFE CABLE.—The Cadiz-Teneriffe section of the Spanish National Submarine Telegraph Company's cables was interrupted on the 12th inst. to remove a fault which had occurred in the neighbourhood of Teneriffe. Communication was restored on the 16th inst. by the ss. "Dacia," which grappled the cable in 2,020 fathoms, and completed the repair in four days. We are informed that this deep water was met with within nineteen miles of Santa Cruz de Teneriffe.

THE HOLBORN RESTAURANT INSTALLATION.—This installation has now been going since February of last year. The engines, two sixteen horse-power, supplied by Ransome Head, and Jefferies, of Ipswich, have worked very satisfac-

Digitized by Google

torily from the beginning. We are informed that, although they have been worked very considerably above their guaranteed power during the last few months, they have shown no sign of undue wear, and still run very well. The automatic-governor fitted on them is found, we are told, to control the speed with ease. We think these facts speak well for the makers.

King's College, London.—Professor W. Grylls Adams, F.R.S., will continue the course of lectures on light, and the scientific principles involved in electric lighting, &c., during the remainder of the session. A course of practical work in electrical testing and measurement, with especial reference to electrical engineering, will also be carried on under his direction in the Wheatstone laboratory. The lectures will be given once a week—on Mondays, at 2 p.m.—and the laboratory will be open on Wednesday and Friday from 1 to 4. Further particulars can be obtained of Professor Adams, at King's College, Strand, W.C.

The Western Electric Company.—We have received a few notes as to the work turned out by this company during the past year intended for our annual article, but, inasmuch as they arrived too late to be incorporated therein, we must content ourselves with giving the pith in this short note. The company has erected a new factory at Chicago, and now employs something like 750 hands at this and other establishments in America. These are principally occupied in the manufacture of telephonic apparatus. They have also established an agency at 59, Moorgate-street, E.C., for the sale of their goods in England. Altogether the company's affairs seem to be in a progressive state.

The Skrivanow Battery.—This battery, as used to supply current to the headlights of the ballet girls in *La Farandole*, at the Paris Opera, is composed of the following elements:—A plate of zinc, and chloride of silver wrapped in parchment paper, constitute the electrodes, and these are plunged in an alkaline electrolyte. The whole is enclosed in gutta percha cells. The size of the battery is 5 centimetres high, 6 centimetres wide, and 15 millimetres thick. The manner in which these batteries are fitted on the dancer is very ingenious. The cells used are arranged in the buckles of a girdle round the girl's waist, the real fastening being at the back. The wires are led round to the back, and then pass up under the hair to the ring which fits on the top of the head and carries the lamp and glass star.

Joint Stock Companies.—The following have been struck off the register of joint stock companies as from the 15th inst.:—Anglo-Australian Telegraph Company, Calcutta and Singapore Telegraph Company, Franco-Egyptian Telegraph Company, Home and Foreign News Telegraph Company, India, Australia, and China Submarine Telegraphs, International South Transatlantic Telegraph Company (two companies of this name have been struck off, one registered 4th December, 1869, and the other 11th January, 1870), Jersey and Guernsey Telegraph Company, London and New York Telegraph Company, Manila and Hong Kong Submarine Telegraph Company, National Telegraph Manufacturing Company, New York and London Direct Telegraph Company, Ocean Telegraph Company, Telegraph Factory and Maintenance Company.

The Graduation of Galvanometers.—In a recent note to the Academy of Sciences, Paris, M. E. Ducretet, says on this point:—"I make the directing magnet a kind of electro-magnet by furnishing it with coils of a certain resistance. To magnetise the steel bar of which the magnet is composed, the current from several Daniell cells of large surface (the ·22 metre in height, circular-shaped sized is the best) is sent through its coils for a given time. The circuit of these coils having a large resistance the battery is not polarised. Each time that the graduation is to be verified the magnetised bar is brought to its primary intensity by sending a similar current through it for the same period of time. A soft iron bar may be substituted for the steel bar, with suitable coils; they should receive, during the observation, a continuous current from a Daniell battery, which current is interrupted after the observation.

Domestic Electric Lighting.—On the occasion of the recent visit of His Royal Highness the Prince of Wales to Mr. Alfred de Rothschild, at Halton House, near Aylesbury, the mansion was lighted by incandescent lamps. The grounds were lighted by Brush arc lamps, which were erected on the roof of the house, and fitted with reflectors so that their rays could be directed where required. Lane-Fox lamps were used inside the house and conservatory. The current was supplied by Brush dynamos in conjunction with secondary batteries on what is known as the B.T.K. system. The whole work was carried out by Messrs. E. T. Mackrill and Co., of Aylesbury, the secondary batteries, switches, &c., being supplied by the Provincial Brush Company, and made by the Consolidated Company, both of 110, Cannon-street, E.C. The Anglo-Brush Company made the lamps and machines. The whole installation appears to have been a success.

Festivity.—Last week the annual dinner of the Leicester Postal Telegraph *employés* took place, the chair being occupied by Mr. Turner, postmaster. In the course of the evening several speeches were made, some of which contained facts of interest to the telegraph world. Thus, Mr. Goddard, after proposing the toast of "The Postal Service," stated that 142,396 messages were sent from the Leicester office in 1872-3, whilst last year this number had risen to 322,047. Mr. Stone, of the engineering department, who replied to this toast, stated that in Leicester there were 81 miles 678 yards of wire, in connection with which they had 63 offices, representing warehouses, factories, offices, &c., in intercommunication one with another. They had also 33 offices not in communication with the exchange. They could do between 300 and 400 verbal transactions per day in the Telephone Exchange, and if they were taxed to the utmost they could do 800. Other speeches followed, intermingled with songs.

Measuring the Work Absorbed by a Dynamo.—M. Pierre Picard has devised a means for readily measuring the work absorbed or given out by a dynamo. He does this by means of what he calls a statometer, which determines the statometric constant of the machine. The statometer is arranged like a Prony brake. The constant is represented by

$$\frac{\pi P L}{30 c},$$

in which L is the length of arm of the statometer lever, P the weight needed to equilibrate the effect of the current, and to prevent rotation, $c$ the current employed during the experiment. Let us call the statometric constant K. Being given the above-mentioned facts, the work absorbed or given out by a dynamo is furnished by the formula $W = K C N$, in which K is the constant, C the current traversing the machine, and N the revolutions per minute. The work thus calculated is purely theoretical, and will be affected by a co-efficient of increase or decrease, according as the machine is used as receiver or generator.

THE METROPOLITAN BRUSH COMPANY.—In the Court of Appeal, on Tuesday last, before the Lord Chancellor, the Lord Chief Justice, and Lord Justice Cotton, Mr. Bernard Ollendorf appealed from the decision of Mr. Justice Chitty, who refused to remove his name from the list of contributories to the company, on the ground that the allegation that there had been a substantial suppression of material facts in the company's prospectus had not been made out. The company was formed in May, 1882, with a capital of £1,000,000, divided into 200,000 £5 shares. Mr. Ollendorf applied for 300 shares, and 100 were allotted to him, on which he had paid in calls altogether £300. The allegation was that the company had suppressed facts in their prospectus with regard to the Lane-Fox patent which altogether changed the marketable value of the shares.—Mr. Waller, Q.C., and Mr. Proctor appeared for the appellant; Mr. Romer, Q.C., and Mr. Bradfield for the respondent company. Without calling on the counsel for the respondents, their lordships dismissed the appeal, on the ground that there had been no intentional misrepresentation of facts in the company's prospectus. The appeal was dismissed with costs accordingly.

THE HOLBORN INSTALLATION.—We understand that the *Gas Journal*, from which we gave a quotation in our last issue, was rather premature, to say the least of it, in the conclusions arrived at over the circular issued to the consumers of electricity on the Holborn-viaduct. No doubt with our contemporary "the wish was father to the thought," and the most was made of what may after all prove to be a very harmless circular. It will be seen from another column that, so far from having resolved to abandon the Holborn-viaduct, the Edison-Swan Company is consolidating its offices there, and we feel pretty well assured that where the offices are the light will not be far distant. Our investigations into the question of this circular lead us to suppose that it was the outcome of ordinary business, that two large companies having been amalgamated, and passing through the throes of reorganisation, it became necessary to consider most thoroughly all the work in hand to put the new company in the position of being able to deal with the work to the best advantage, not only as regards the present but also in regard to the prospects of the near future. So far, then, as we can judge the circular partakes more of the nature of a precaution than of a conclusion. The question of withdrawing the light has not been definitely settled, nor perhaps is it likely to be settled in the manner indicated by our contemporary.

MORNING GLOW.—Professor Guy, of Saint Louis, Perpignan, France, writes to *Cosmos Les Mondes* that at 4 a.m. on the 8th inst., on getting out of bed, and before lighting the candle, he saw the reflection of a flash of lightning in his room. He ran to the window and saw a beautiful whitish glow extending over the whole of the southern part of the sky, from the horizon to the zenith. His window, he says, looked south, and he could see nothing of the northern part of the sky. It being 4 a.m., and the moon having set at Perpignan at 2 hours 42 minutes, Professor Guy says that what he saw could not possibly have been clouds lighted up by the moon. Along the southern horizon was a band of black clouds of about 15° in height. The upper part of this band was illuminated at intervals by flashes of lightning like those seen in summer. This intermittent illumination was undoubtedly, says the professor, due to lightning, but the cause of the general glow, which lasted till a quarter to five, when the sky became clouded over, is not so easy to determine, though it may be attributed to electricity. Possibly the upper currents of electricity flowing towards the poles are able to illuminate the layers of rarefied air which they traverse and to give us the feeble whitish glows which are sometimes seen. Such was probably the cause of the effect seen at Perpignan, and the professor thinks that the frequent flashes of lightning which illuminated the horizon showed that there was a great deal of electricity in the air, and gives some resemblance of truth to his supposition.

THE LANCASHIRE AND CHESHIRE TELEPHONIC EXCHANGE COMPANY.—This company are making very fair progress in the district where they have located themselves. They have exchange or private lines in 41 towns, and the progress made during the past year in some of the larger of these will be seen from the following figures:—At the end of 1882 the Manchester Exchange had 796 subscribers, and there were 278 private lines; at the end of 1883 these totals had increased to 902 and 285 respectively. The figures were as follow for the other large towns of their system, viz.:—

| Name of Town. | End of 1882. Exchange Subs. | Private Lines. | End of 1883. Exchange Subs. | Private Lines. |
|---|---|---|---|---|
| Warrington ... | 20 | 4 | 24 | 5 |
| Liverpool ..... | 674 | 174 | 863 | 260 |
| Birkenhead ... | 30 | — | 84 | 5 |
| Southport ..... | 7 | — | 62 | 3 |
| Barrow ..... | 27 | 16 | 37 | 19 |
| Preston ..... | 117 | 6 | 132 | 6 |
| Blackburn ... | 82 | 17 | 122 | 12 |
| Accrington ... | 22 | 10 | 39 | 10 |
| Burnley ..... | 34 | 2 | 32 | 4 |
| Colne & Nelson | 23 | — | 33 | 1 |
| Wigan ..... | 52 | 4 | 34 | 8 |

The total number of exchange subscribers at the end of 1882 was 1,978; at the end of 1883 this had risen to 2,498. The private lines at the end of 1882 numbered 587, and at the end of 1883 they reached 741. Evidently the Lancashire and Cheshire Telephonic Exchange Company are not standing still.

TELEPHONIC DEVELOPMENT.—On Tuesday last Professor S. Thompson delivered a lecture in Bristol on "Recent Developments in the Telephone." He traced the various improvements that had been made in this instrument since the days of Reiss, mentioning in this connection the names of Bell, Edison, Dolbear, Gower, Ader, Hughes, Blake, Johnson, and Hunnings. Referring to the extension of the telephonic system of communication in America Professor Thompson said that there were more telephones in New England than in Old England, more in Leadville than in London, more in Illinois, Indiana, Ohio, and Iowa than in England, Ireland, Wales, and Scotland, more in Honolulu than in Bristol. As a contrast to this, in Cassel, a town of 50,000 inhabitants, where twenty years ago Reiss had shown the telephone, there were now only sixteen subscribers, though the exchange rental was but £10 per annum. Speaking of overhead wires, the lecturer remarked that the use of silicium bronze wire for overhead lines was rapidly increasing. These wires were stronger, much thinner, and of better electrical conductivity than the usual iron telegraph wires. The greatest of all improvements would be that of putting the unsightly overhead wires underground. This was actually done in the Post Office Exchange at Newcastle, in the Paris Exchange, with its 5,000 subscribers, as well as at New York and Chicago. It was true that the United Telephone Company were promoting a Bill giving power both to lay wires underground and to convey them overhead but he doubted whether in the present tone of

Digitized by Google

public opinion any such powers with respect to overhead wires would be granted by Parliament. It had been stated by interested parties that telephonic instruments would not work on underground lines, and that to put the wires underground was practically to abolish the telephone. This might be true of those companies who used weak and antiquated patterns of instruments, but experience showed that modern transmitters, such as those of Ader and Hunnings, worked without difficulty underground on direct circuits.

THE COPPER VOLTAMETER.—Dr. Hermann Hammerl publishes in the December number of the *Elektrotechnische Zeitschrift* the results of a series of experiments he undertook with a view to finding out under what conditions and within what limits the ordinary copper voltameter is reliable. Dr. Hammerl always employed two voltameters in his researches; the one which was kept unaltered during any one set of experiments he used as a standard, whilst he varied the conditions of the other, and so, by comparison of the weights of copper deposited by the same current in both instruments, could judge how these variations affected the accuracy of the voltameter under test. A tangent galvanometer was also inserted into the same circuit as a check on the standard voltameter, and a rheostat permitted any desired intensity of current to be maintained during each experiment. He arrived at the following conclusions:—The plate containing the deposit of copper should be rinsed with distilled water, then dried between sheets of blotting paper, and if nearly dry may be warmed a little to accelerate the process; but it must not be heated whilst wet, as otherwise the deposited copper would become partly oxidised. It is immaterial whether a plate of platinum, pure and simple, or one of platinum with a copper coating be used to receive the deposit. To avoid polarisation and to maintain a uniform density of the liquid it is desirable to stir it during the whole time the voltameter is in use. To keep the liquid in motion by boiling is, however, not permissible, as a temperature of 90deg. centigrade is quite sufficient to oxidise all the copper deposited. The density of the current has also considerable influence on the accuracy of a voltameter. The maximum current which can safely be employed is ·7 ampere per square decimetre of surface, or, in English measure, 2·15 square inches for every ampere of current; roughly speaking, half an ampere of current for every square inch of surface—an easily-remembered rule. Since the deposit takes place preferably on the corners and edges of the plate, where the density of the current is consequently greater than in the middle, it is desirable to have a minimum of the former to a maximum of surface, and square plates are therefore preferable to rectangular ones. The distance between the plates was in most of the experiments about 1 inch. If this be reduced to about $\frac{1}{8}$ inch polarisation begins to show itself at once with a density of current of 0·3 of an ampere per square inch of surface.

CHANGE OF VOLUME OF METALS AT MELTING.—Herr E. Wiedemann has made a series of experiments on the expansion of volume at melting point, and the relative rates of cooling of tin and certain alloys of bismuth and lead. The results of these experiments were communicated to the *Annalen der Physik und Chemie*, and have been abstracted for the January number of the *Journal* of the Chemical Society, from which we quote:—The dilatometer method was employed. The substance was enclosed in a closely-fitting glass cylinder, at the upper end of which was fixed a capillary tube. The most convenient liquid for filling the apparatus was found to be oil, which has the advantage of not evolving air when heated to 200deg.; moreover, it does not possess an appreciable vapour-tension at that temperature. When heated above that point the oil attacks the metal. The rate of cooling was determined by heating the metal to 260deg. in an iron vessel. A thermometer protected by a glass cap filled with oil was enclosed within the molten mass. The whole apparatus was then immersed in a double walled-metallic vessel, the intermediate space between the walls being filled with water. The intervals of time required for cooling five degrees were carefully measured; the reciprocal value for these times may be taken as a measure for the velocity of cooling of the metal. In three experiments it was found that tin on melting expanded in volume 1·76, 1·69, 2·20 per cent. These results are in direct contradiction to those of Nies and Winkelmann, who melted a large quantity of the metals and then dropped in a solid fragment of the same metal, and observed whether this fragment floated or sunk. But the author points out that in this method it would be exceedingly difficult to avoid convection currents, which would be liable to carry up the solid fragments to the surface in the centre of the vessel. Experiments also proved that soft solder expands almost 2 per cent. of its volume in melting. *Alloys of Bismuth and Lead.*—$Pb_2Bi$ of sp. gr. 11·4 begins to show an increase of expansion at about 120—136deg., which reaches its maximum at 180deg. When heated to 240deg. and allowed to cool, the temperature remained constant for long intervals of time at 180deg. and 125deg., the two melting points of the alloy. BiPb, sp. gr. 11·03, expands abnormally between 127deg. and 132deg., melts at 146deg. and 125deg. $PbBi_2$, sp. gr. 10·96, expands abnormally between 126deg. and 132deg., melts at 140deg. and 124deg. $PbBi_4$, sp. gr. 9·73, expands most markedly between 120deg. and 136deg., melts at 125deg. and 200deg. $PbBi_8$, sp. gr. 8·6, melts partially between 125deg. and 130deg., contracts between 172deg. and 204deg; its melting points are 170deg. and 120deg. The results of these experiments show that these alloys contain a definite compound of composition between PbBi and $PbBi_2$, whose melting point is about 125deg., and in which the excess of one metal, lead or bismuth, as the case may be, dissolves. For equal increments of temperature, the proportion of the metal dissolved rapidly increases. From the changes of volume at temperatures above the first melting point one can conclude whether the metal in excess expands or contracts on melting. The experiments would seem to indicate an expansion of lead and a contraction of bismuth, a result in accordance with previous observations. For example, the alloy $PbBi_8$ consists of an alloy of low melting point, in which the excess of bismuth dissolves; if it be gradually warmed to 120deg., the alloy and the excess of bismuth expand regularly. At this temperature the alloy melts with marked expansion, and contains the solid bismuth in suspension; above that point, the bismuth gradually dissolves and melts, while the rate of expansion *pari passu* decreases.

NEW ATLANTIC CABLES.—*The Times* of Jan. 23 contained a letter on this subject from Mr. J. W. Mackay. With reference to Mr. Mackay's remarks as to inspiration from existing companies, we have reason to believe that his idea is altogether incorrect. The companies have neither taken steps to advise nor inspire newspaper articles, nor have they troubled themselves very much about Mr. Mackay's work. It is sufficient for them to know that their cables are sound, and quite capable of doing double the work at present to be had. The managers are ready to consider the question of Mr. Mackay's competition when called upon to do so. We now give his letter:—"9, Rue Tilsitt, Paris, Jan. 19. Sir: For some time past there have been published in many of

Digitized by Google

the London papers, and notably in the *Pall Mall Gazette*, a series of sneering articles about the Transatlantic Commercial Cable Company, in which Mr. Bennett and myself are interested. I do not know whether these articles have been inspired by professional promoters of companies, or by persons interested in the cable companies now existing. It is, however, of little consequence who is at the bottom of these articles; but in the interests of the general public, of the Press, and of the merchants who use the transatlantic cables, I think that a few words from me will not be out of place, with a view to correcting possible misapprehensions. The *Pall Mall Gazette* of January 16th, for instance, says:—'There is some mystery about this matter, and the part which Mr. Mackay is playing in the combination seems to require some explanation. It is a very big business, and may have great results one way or the other. It is possible that when the scheme appears the name of Bennett may not be quite so prominent as people have been led to expect.' Sir, I ask leave to state publicly in the columns of *The Times* that there is no mystery about the matter at all, nor, indeed, has there ever been any. Mr. Bennett and myself ordered last September two cables from Messrs. Siemens. Any persons interested in obtaining further information about these cables can procure it at the business office of Messrs. Siemens, 12, Queen Anne's-gate, Westminster. Suffice it to say here that about a thousand miles of one of these cables have been completed, and the steamer 'Faraday' leaves before the end of this month with this portion of the cable on board, of which it will lay a part to connect Dover Bay and Cape Ann, Massachusetts, and the remainder from Dover Bay eastward. On the completion of this work the 'Faraday' will return to England, and will leave again by the end of May or the beginning of June to complete the first line of communication between England and America. The second cable will be laid in the course of the summer. We own both cables ourselves, and we intend to keep them. We have no intention of entering into any agreement or coalition whatever with the existing companies. Owning the cables ourselves, and not being required to satisfy the wants of small shareholders, who, having but small capital at their disposal, are obliged to expect quick returns, and clamour for mercy for their 'one little ewe lamb,' we are in a position to take our stand and defy all attempts at coercion. In founding this new transatlantic cable company we were of opinion that the time had come to give the public on a permanent basis a somewhat cheaper and at the same time a thoroughly reliable and prompt cable service. We have not started on this enterprise in order to strike the existing companies, or with a view of entering into a systematic war of rate cutting. The above is a brief statement of our objects and intentions clearly defined. I have also stated how far the mechanical part of the enterprise has progressed. I do not deny that 'it is a very big business,' and I hope that it may have 'very great results,' but I do not see that there is any 'mystery' in it whatever."

THUNDERSTORMS.—A few days since Professor Tait gave the second of two lectures on thunderstorms in the Queen-street Hall, Edinburgh. We shall hope to give the pith of both these lectures, particularly the theoretical pith, in our next issue. Meanwhile we give an abstract of the second lecture. Professor Tait began by remarking that the meteorological effects of a thunderstorm were the extraordinary amount of vapour in the air, and the consequent immense fall of rain and hail. He said that to find out the amount of energy involved in changes of that kind was an interesting question. In considering it the results they arrived at were astounding. To evaporate a tenth of an inch of water on a square foot of ground required a power equal to one horse for half an hour, so that to condense one-tenth of an inch of water on a square mile they would require one million million horses working for the same time. They had then no difficulty in understanding how it was that hurricanes and typhoons could be produced by the amount of energy in the heat formed out of that small quantity of water in condensing from the vaporous into the liquid form. Going on to speak of the three forms of lightning—forked, sheet, and globe—he said that forked lightning was simply the same thing, on an incomparably larger scale, as the sparks they got from an electrical machine; and that the "flash" was simply the air rendered incandescent by resistance to the passage of the electricity, in the same way as the carbon in the Swan lamp was rendered incandescent by a current of electricity being forced along it. A brilliant flash of lightning lasted, it was computed, only one-millionth part of a second. Experiments had been made which went to show that a bright object required to be seen for one-tenth of a second before its full brightness was realised by the eye. If it lasted only half that time, it produced only half its brightness, and so on; consequently a flash of lightning was only seen at a hundred-thousandth part of its proper brightness. If a flash of lightning lasted the thousandth part of a second, objects would be as brilliantly illuminated by it as they were in the sunlight; and if it lasted one-tenth of a second it would have the brilliancy of 100 suns, and would be blinding in its effects. Sheet lightning was merely the clouds and vapour in the air lighted up by a forked flash, which itself was hidden from view; and as to the curious phenomenon known as globe lightning, they knew little about it, as they had never been able to produce it by experiments; and it had never been observed by any trained observer. Speaking next of thunder, he showed how it was caused by the sudden expansion of the air on all sides of the lightning flash, followed by an almost instantaneous inrush of the air when the flash had passed. Thunder, he said, was never heard more than fifteen miles off from the flash of lightning; and he remarked that the popular way of judging the distance, of allowing a mile for every five seconds interval between the flash and the thunder, was nearly correct. The old notion that there was something sulphurous connected with the discharge of electricity in the air had been discovered to be incorrect. The sulphurous smell had nothing whatever to do with sulphur, but with the great production of ozone, which was merely a modified form of oxygen. As to the peculiar marks which lightning often left on a human body it had struck, the old notion was that they were a sort of photograph of some tree or object in the neighbourhood which had attracted the lightning. These were, however, caused by a disturbance in the nature of bruising of the small capillary vessels under the skin. Dealing next with the difficult question of the origin of electricity, Professor Tait remarked that the old idea that it was due to the friction of the air was untenable. A French investigator had suggested that every time that water containing salt in solution was evaporated, the vapour which came off was always charged with electricity. That, said the lecturer, was probably not far from true, though it was not the whole truth. His own idea at present was that electricity was caused by the friction of the water vapour particles against the air particles, because when two different bodies were in contact they always gave off electricity.

## ELECTRO-CHEMISTRY.

### INORGANIC.

BY DR. G. GORE, F.R.S.

(CONTINUED FROM PAGE 223.)

**Electrolysis of Oxides of Iodine, &c.**—By immersing a sheet of aluminium in a solution composed of twenty-six grains of dry iodic acid, and five ounces of water, I observed that much gas was evolved; the metal acquired a strong odour of absorbed iodine, and had increased about 16 per cent. in weight (*Proceedings* Birm. Phil. Soc., Vol. IV., Part I.).

A solution of one part of iodic acid and ten parts of water yields oxygen gas at the anode, and iodine alone at the cathode, the latter being separated by secondary action of hydrogen, liberated by the electrolysis of the water (Connell). According to Buff, however (*Ann. Chem. et Pharm.*, Vol. CX., p. 257), the iodic acid is resolved by the current into hydrogen and iodic anhydride, which latter is decomposed by the water, thus producing iodic acid and free oxygen (Watts's "Dictionary of Chemistry," Vol. III., p. 300). The electrolysis of periodic acid does not appear to have been yet examined.

When an iron or copper plate, or better, a zinc and copper plate, connected externally by a wire, are immersed in strong solution of potassium iodate at 60° F., complete reduction to potassic iodide occurs. Potassium bromate is similarly reduced to bromide; but potassic chlorate slowly and incompletely to chloride. (G. Pellagri, Watts's "Dictionary of Chemistry," Vol. VIII., Part 2, p. 1668.)

**Electrolysis of Bromide of Iodine.**—When an aqueous solution of starch and iodine, which has been turned yellow by dissolved bromine, is subjected to electrolysis, it becomes orange coloured at the anode by liberation of bromine, and blue at the cathode by separation of iodine. (*De la Rive, Ann. Chem. et Phys.*, Vol. XXXV., p. 164.)

**Electrolysis of Iodides, Bromides, and Chlorides.**—By electrolysis, iodine and bromine are separated from solutions of iodides and bromides. Iodates and bromates are produced simultaneously from the iodides and bromides of the metals of the two first groups, especially in concentrated solutions. When the solutions of the chlorides, bromides, and iodides contain free alkali, only chlorates, bromates, and iodates are produced. From the insoluble compounds of chlorine, bromine, and iodine, with the metals, suspended in dilute sulphuric or nitric acid, the acid radicle appears at the anode, and the metal at the cathode. (C. Luckow, *Jour. Chem. Soc.*, Vol. XXXVIII., 1880, p. 282.)

**Separation of Carbon.**—C. Atomic weight = 12. A tetrad cation. "An excess of silicon fused with potassic carbonate sets free carbon." Deville states that metallic aluminium liberates carbon from carbonate of potassium in a state of fusion (*Chemist, New Series*, Vol. IV. p. 481). I have observed the same with fused sodic carbonate. According to Phipson, magnesium by contact with fused carbonate of sodium set free carbon abundantly. (*Proc. Roy. Soc.*, 1864, Vol. XIII., p. 217, also *Chemical News*, Vol. IX., p. 219.)

The following are some experiments of mine (*Proc. Birm. Phil. Soc.*, Vol. IV.):—A fused mixture of 200 grains of pure sodic hydrate, 170 grains of pure precipitated silica, and 610 grains of the mixed anhydrous carbonates of sodium and potassium was electrolysed by means of a current from 10 Smee elements, with a sheet platinum anode, and a thick platinum wire cathode. Conduction was free, and much oxygen, which relighted a red-hot splint, was liberated at the anode. Dark streams flowed from the cathode, sodium was also set free, and if the cathode was only slightly immersed bubbles of vapour of sodium were emitted, and took fire at the surface of the liquid. After one hour's action the platinum anode had lost ·37 grain in weight. The cathode had a feebly adherent rough deposit of a dull jet black colour upon it. This deposit was subsequently washed and dried; a portion of it burned with a glow when heated to redness, and left a minute residue of grey platinum, it also deflagrated with fused nitre below a red heat, and vividly by heating with potassic chlorate. It did not dissolve nor evolve any gas in a mixture of strong nitric acid and pure concentrated hydrofluoric acid. It was, therefore, carbon.

As carbon was not readily deposited from the fused carbonates of potassium and sodium, whilst silicon was deposited from fused silicofluoride of potassium, and as "an excess of silicon fused with potassic carbonate sets free carbon, but silicon with an excess of the carbonate liberates carbonic oxide," the carbon liberated in this experiment may have been a secondary result, and an effect of previously deposited silicon reacting upon the fused mixture. It was with the expectation of this effect that I employed silica in the mixture.

I also electrolysed in a platinum cup a fused mixture of 475·2 grains of 97·1 per cent. sodic carbonate (containing as impurity only water) and 217·4 grains of borofluoride of sodium, by means of the same current, a sheet platinum anode and thick platinum wire cathode. Conduction was free. Gas arose from the anode, and a small amount of black deposit formed upon the cathode. After having been well washed the deposit was dried, put on a platinum dish, and heated to redness; it burned with sudden incandescence until nearly the whole was consumed. It was, therefore, nearly wholly carbon.

I electrolysed in a platinum cup a fused mixture of 274 grains of pure sodic carbonate, 375 grains of pure potassic carbonate, both anhydrous, and 206 grains of crystallised boracic acid, at a red heat, by means of a current from eight Smee elements and platinum electrodes. There was free conduction, much gas from the anode, and an instant jet black deposit formed upon the cathode, and could be burned off at a red heat. Metallic sodium was set free at the cathode, especially during deep immersion. The anode was soon much corroded, and acquired a very smooth surface, and platinum was deposited upon the cathode. No free carbon was ultimately found.

**Electrolysis of Carbonic Anhydride.**—$CO_2$. Molecular weight = 44. I have examined (*Phil. Trans. Roy. Soc.*, 1861) the action of a voltaic current on carbonic anhydride liquefied by great pressure. With electrodes of thin platinum wire 1-10th of an inch apart, and the liquid below 32°F., not the slightest conduction occurred with a current from 40 Smee elements; and sparks from a Ruhmkorff coil, which passed through 3-8ths of an inch of cold air in an alternate portion of the divided circuit, would not pass through the liquid. In another trial, with the wires about 1-70th of an inch asunder, sparks from the coil, which were passing freely through 9-32nds of an inch of cold air in the alternate circuit, passed occasionally through the cold acid and exhibited a pale blue colour. The liquid is, therefore, a strong insulator of electricity. Bleekrode also (*Proc. Roy. Soc.*, 1876, p. 325) tried the same liquid with a current from 5,540 chloride of silver elements. A spark jumped between the poles, and the tube exploded. He concluded that the liquid is a very bad conductor. Cailletet (*Comptes Rendus*, Vol. LXXV., p. 1,271) has also arrived by experiments at the same conclusion.

I tested by experiment in an approximate manner the relative degrees of conduction resistance of distilled water, and of the same saturated with carbonic anhydride at 60°F. and at atmospheric pressure. No conspicuous difference was observable.

I also passed an electric current from four Smee elements by means of platinum wires during one week through very dilute sulphuric acid in a large U glass tube, one leg of which was kept full of a mixture of carbonic oxide and carbonic anhydride gases. No carbon was deposited. Fuming sulphuric acid, also a syrupy solution of phosphoric acid were saturated with dry carbonic anhydride, and then electrolysed by means of platinum wire electrodes and currents from 112 Smee cells in single series; no carbon was deposited (*Proc. Birm. Phil. Soc.*, Vol. IV.).

**Electrolysis with Anodes of Carbon.**—According to A. Bartoli and G. Papasogli, in liquids whose electrolysis is not

Digitized by Google

accompanied by evolution of oxygen at the anode, anodes of wood-charcoal, gas-carbon, and graphite are not disintegrated or dissolved, or suffer any loss of weight. In those in which oxygen is evolved, those anodes are partly disintegrated, and and partly oxidised to carbonic oxide and carbonic acid gases, together with other products; graphite used in those liquids never imparts a colour to the electrolyte, but anodes of wood-charcoal and gas-carbon, previouslv purified, colour it black, both in alkaline solutions and in those of certain acids and salts, by the formation of a black substance which they term mellogen, the composition of which is represented by the formula $C_{11}H_2O_4$, together with traces of benzo-carboxylic acid; graphite anodes in those liquids produce graphitic acid $C_{11}H_2O_3$. In alkaline electrolytes, anodes of wood-charcoal gas-carbon and graphite produce mellic acid $C_{12}H_6O_{12}$; pyromellic acid $C_{10}H_6O_8$; hydromellic acid $C_{15}H_{12}O_{15}$, and another body, apparently hydro-pyromellic acid $C_{10}H_{10}O_8$ (*Jour. Chem. Soc.*, Vol. XLIV., 1883, p. 592; *The Electrician*, Vol. XI., pp. 28 and 101). For the electrolysis with electrodes of wood charcoal, gas carbon, and graphite, of solutions of hydrochloric, hydrobromic, and hydriodic acids and their potassium salts, potassic cyanide, sulphuric and nitric acids and their salts, hydrogen and sodium sulphite, arsenic acid, boracic acid, alkaline hypochlorites, permanganates, bichromates, and chlorates, chromic acid, mellic acid, oxalates, formiates, acetates, &c., and sodic pyrogallate, see also the same paper.

## THE THEORY OF DYNAMO-ELECTRIC MACHINES.

(CONTINUED FROM PAGE 231.)

### 6. *Work done by Electromotive Force and by Mechanical Force.*

To express the work done in unit of time by the E.M.F., E, as determined above, we must multiply its value by $i$, the intensity of the current passing through the two halves jointly of the rotating coil. From equation (8) we now have

$$E\,i = n\,(W' - W'')\,i\,v - \rho\,i^2\,v \quad . \quad . \quad . \quad (9).$$

This work may be compared with work of another kind, for the other currents, including the magnets, perform on the coil a certain amount of mechanical work, which we proceed to determine.

Take any one member of the coil, which latter in each of its halves is traversed by the current $\frac{i}{2}$. The work done by the mechanical force acting on this member in time $d\,t$, assuming that the current exciting the force does not change its position, and that the intensities of all the currents are constant, is given by

$$\frac{i}{2}\,\frac{d\,W}{d\,t}\,d\,t.$$

Hence in a semi-revolution the work done will be

$$\frac{i}{2}\,(W'' - W'),$$

and as this time $= \frac{\tau}{2}$, the work in a unit of time is

$$\frac{i}{\tau}\,(W'' - W') \text{ or } i\,(W'' - W')\,v.$$

As there are $n$ such members, the total mechanical work, T, done in a unit of time on the whole rotating coil is given by

$$T = n\,(W'' - W')\,i\,v \quad . \quad . \quad . \quad . \quad (10)$$

If we compare this with the work of the electromotive force, given by equation (9), we see that it differs only in sign, and in the addition of the expression $-\rho\,i^2\,v$, which is the work done by the E.M.F. induced in the rotating coil by its own current. We may therefore write

$$E\,i = -T - \rho\,i^2\,v \quad . \quad . \quad . \quad . \quad . \quad (11)$$

### 7. *Determination of the Magnetism in the Electro-magnets of the Dynamo Machine.*

In order to throw the foregoing theoretical results into a more practical form, we must obtain expressions for the strength of the electro-magnets, which form part of the dynamo machine.

First, we have the fixed magnet. The magnetic moment, which determines the force it exerts in the space between its poles, is not proportional to the intensity of the current passing through its enveloping coil, but follows another law. With small current-intensity it does, indeed, increase nearly as that intensity; but with higher intensities the increase gets slower and slower, and approaches a limiting value. This has been expressed by Frölich* in the following equation:

$$M = \frac{A\,i}{1 + a\,i} \quad . \quad . \quad . \quad . \quad . \quad (12)$$

where M is the magnetic moment and A and $a$ are constants. Probably this is not the best form for the equation; but from its simplicity it may well be employed here, where so many circumstances intervene that only approximate results are possible.

With very small current-intensity the remaining magnetism, from the previous magnetising, has to be taken into account. It may, indeed, be neglected for a machine in full work, but at first starting it is of importance, and for this reason we shall return to it later. For the present we will simply use equation (12).

We have next to consider the magnetism of the iron core of the rotating coil. This is difficult of determination, however, because, as observed in Section 1, it is induced by two different magnetic forces, that of the fixed magnet and that of the current passing through the rotating coil. The first is proportional to the magnetic moment M of the fixed magnet, and if it acted alone would produce a magnetic moment which we might express (as we have the magnetic moment due to the current $i$ in the fixed magnet) by an expression

$$\frac{C\,M}{1 + \gamma\,M},$$

where C and $\gamma$ are constants. The second force, which is at right angles to the first, would produce, if it acted alone, a magnetic moment which might be expressed in the same form as above, if we substituted for M another magnitude, standing in the same relation to the magnetising force exercised by the coil on its iron core, as the magnetic moment M to the magnetising force exercised on the core by the fixed magnet. We will call this magnitude N, and define it by saying that the magnetic moment which the rotating coil would by itself produce in the core is given by the expression

$$\frac{C\,N}{1 + \gamma\,N}.$$

This number, N, must, of course, be proportional to the intensity of current in the rotating coil, which, taking the two halves together, is $i$; hence we may put

$$N = B\,i \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad (13)$$

where B is constant for each particular machine.

Now, if both these magnetising forces act together on the core, its magnetism will clearly be increased. If we call the magnetic moment of the total magnetism P, we must first form the resultant of the two forces M and N, which is $\sqrt{M^2 + N^2}$. Adopting the same form of expression as before, we may now give the following expression for P:—

$$P = \frac{C\,\sqrt{M^2 + N^2}}{1 + \gamma\,\sqrt{M^2 + N^2}}.$$

---

* *Electro-techn. Zeitschrift des Berl, Electro-tech. Vereins* (2), 1881, p 139.

Digitized by Google

But, as already mentioned, this can only be taken as an approximate value for the magnetic moment, as a function of the magnetising forces; and this holds especially true of the denominator of the fraction. Again, the occurrence of the square root in this denominator is very inconvenient for calculation, and it thus requires simplifying. Now, of the two magnetising forces the one is produced directly by the current, and is therefore proportional to $i$. The other is also indirectly proportional to the current, since this latter induces the magnetism in the fixed magnet, which in its turn exercises the force under consideration. Hence the degree of accuracy of the result will not be much impaired, if instead of the square root in the denominator we insert a quantity proportional to $i$, so giving it the same form as the denominator of the fraction in equation (12). We shall now have the following equation:—

$$P = \frac{C\sqrt{M^2 + N^2}}{1 + \beta i} \quad . \quad . \quad . \quad . \quad . \quad (14)$$

where $\beta$ is a new constant, to be determined separately for each machine.

The axis of this magnetic moment P has the same direction as the resultant of the magnetising forces due to the fixed magnet and the rotating coil respectively. If $\phi$ and $\left(\frac{\pi}{2} - \phi\right)$ are the angles made by this axis with the two perpendicular directions of the forces (the first being opposite to the axis of the fixed electro-magnet) we have, to find $\phi$, the equations

$$\cos\phi = \frac{M}{\sqrt{M^2 + N^2}}; \quad \sin\phi = \frac{N}{\sqrt{M^2 + N^2}} \quad . \quad . \quad (15)$$

By help of these we may resolve the magnetic moment P into two components along the two directions of force. These components, $P_1$ and $P_2$, which will be found convenient in what follows, are given by

$$\left.\begin{aligned} P_1 &= P\cos\phi = \frac{CM}{1 + \beta i} \\ P_2 &= P\sin\phi = \frac{CN}{1 + \beta i} \end{aligned}\right\} \quad . \quad . \quad . \quad (16)$$

8. *Work Done by Mechanical and Electromotive Forces in the case where the Core of the Rotating Coil is at Rest.*

Having obtained expressions for the magnetic moments, we can now determine the work done by mechanical forces during the running of the machine.

We shall begin by making an assumption, which does not, indeed, hold for machines of ordinary construction, but which greatly simplifies the investigation and gives results which can be easily applied to ordinary machines. This is, that the iron core does not share in the rotation of the coil, which rotates alone, and is thus exposed to two forces, one coming from the fixed electro-magnet outside, and the other from the magnetised iron core inside.

The mechanical force which the fixed electro-magnet exerts on the rotating coil is, on the one hand, proportional to the magnetic moment M of the fixed magnet, and, on the other hand, proportional to the magnetic moment of the coil, and therefore to the magnitude N. The work done by this force in a unit of time, which must also be proportional to $v$, the number of revolutions, will therefore be represented by $MNv$, multiplied by some constant. But, for the direction of rotation, which will alone enable the machine to generate a current, and which we have called the positive direction, the mechanical work is negative, because the mechanical force is opposed to such rotation, and has to be overcome by an external force. Hence it is well to express this by giving the above constant a negative value, say $-h$. Then the expression for the work to be determined is $-hMNv$.

Strictly speaking, we should distinguish two different forces as regards the fixed magnet; first, that due to the magnetised mass of iron it contains; and, secondly, that due directly to the current passing through its enveloping coil. But in all machines hitherto constructed the latter is very small as compared with the former, and therefore we may neglect this distinction and treat the fixed magnet as a whole.

The other mechanical force, *i.e*, that with which the iron core acts on the coil surrounding it, is, firstly, like the former, proportional to N; secondly, it depends on the magnetic moment of the iron core. In this moment, however, we must separate the two components found at the end of the last section. The compotent $P_2$ generates a moment whose axis is coincident with that of N, and therefore has no tendency to cause rotation in the coil. On the other hand, $P_1$ generates a moment whose axis is at right angles to that of N, and therefore produces a moment proportional to $P_1$. The work done during rotation by this mechanical force, which, like the power, is proportional to $v$, and is negative for the positive direction of rotation, may be expressed by $-kNP_1v$, where $k$ is another constant.

Adding the expressions for the two amounts of work, we have for T, the total work done in a unit of time by the mechanical forces, the equation

$$T = -hMNv - kNP_1v. \quad . \quad . \quad . \quad (17)$$

From this equation, by help of equation 11, we can deduce the work due to electromotive forces, as follows:—

$$Ei = hMNv + kNP_1v - \rho i^2 v \quad . \quad . \quad . \quad (18)$$

If in these equations we give to $P_1$ the value found at the end of the last section, we have

$$T = -MN\left(h + \frac{kC}{1 + \beta i}\right)v \quad . \quad . \quad . \quad (19)$$

$$Ei = MN\left(h + \frac{kC}{1 + \beta i}\right)v - \rho i^2 v. \quad . \quad (20)$$

(TO BE CONTINUED.)

## ZINC PRIMARY BATTERIES FOR ELECTRIC LIGHTING.

BY DESMOND G. FITZ-GERALD.

The question of the economic possibility of employing primary batteries for electric lighting is at the present moment attracting great attention; and, although many sanguine anticipations will be found to be fallacious, it may safely be predicted that this attention will increase, rather than diminish, as the possibilities in this direction become better understood. In the meantime—unless electricians possessing an accurate knowledge of electro-chemistry bestir themselves in the matter—the great tribe of those who ignore the doctrine of the Conservation of Energy, who believe in perpetual motion, and scornfully decline to admit that any limit can be fixed to the quantity of work practically obtainable by the consumption of a pound of zinc, will have a famous innings. Indeed, their halcyon days would appear already to have commenced; for it is difficult for any known electrician to perambulate the City without being forced to listen to enthusiastic, albeit somewhat imperfect, accounts of marvellous voltaic combinations which will render quite useless any further endeavours in the direction of electric lighting. Some of these turn out, after a little investigation, to be old acquaintances, based on *recipes* published or privately communicated in times gone by; but in the case of others an element of mystery is maintained in the shape of some exciting or depolarising fluid, the secret of which could not be extorted by the most extreme measures until patents have been secured. Unfortunately, the anticipations of golden returns to follow upon the commercial introduction of these appliances are confirmed rather than weakened by the attitude of scientific caution and reserve, the disinclination to deny on any but concrete grounds, the recognition of the infinite possibilities in Nature, on the part of a man who has thoroughly studied the questions involved. Such a man is bound to admit that, under conditions which are not altogether realisable in practice, it is possible, if not practicable, to obtain a horse-power-hour of electrical work by the consumption of so small a

Digitized by Google

weight as ·8772lb of zinc. Of course the most is made of such an admission—the argument being that a great inventor might reduce, nay, has reduced, this minimum weight to 10 or 12 ounces, or, by a fortunate inspiration, even to 10 or 12 grains. In other directions, also, denials or expressions of scepticism appear to be made in a half-hearted manner which is most encouraging to the speculator. For the man of science is bound always to bear in mind the dictum of Arago: "He who asserts that, outside of the domain of pure Mathematics, anything is impossible, lacks a knowledge of the first principles of Logic." And he may remember also the more ancient apothegm: "He that answereth a matter before he heareth it, it is folly and shame unto him."

It is proverbially difficult to establish a negative proposition, and a syllogism of disproof should always be stated in an affirmative form. A formula which, with its demonstration, I will presently give will therefore be useful to electricians, not only for general purposes, but under the trying circumstances which have been adverted to—when a simple denial of strongly-urged assertions would be unscientific, and a tacit admission of them detrimental. An enthusiast tells you that he knows of a battery which, with an expenditure of "less than an ounce" of zinc will give a horse-power-hour of electrical work; he knows that as a fact, for he has seen the measurements, weighed the zincs, &c. Instead of denying, and provoking statements to the effect that electricity is making rapid strides, new and energetic men are extending the boundaries of the science, the old data are already obsolete, *cum multis aliis*, apply your formula, calculate the value of *e*, and quietly observe that "supposing the consumption of zinc to the horse-power to be exactly one ounce, then the electromotive force of each cell of the battery would be exactly 32·32 volts!" I am bound, however, to admit that even this system will sometimes fail; for in a similar case one City gentleman merely remarked, "Yes, I remember now, that *is* the figure arrived at by the inventor."

Standing somewhat prominently before the public, and apart from the ruck of inventors in this direction—inasmuch as his battery appears to be really a good one, so far as zinc batteries can be considered good from an economic point of view; and because, moreover, he possesses a dangerous amount of electrical knowledge, sufficient to puzzle many of his critics as well as himself—Mr. O. C. D. Ross, M.I.C.E., has not only an invention but also a theory in support of it. Considering in the first place the invention, I will quote the following statement from a report by Mr. F. Ormiston in relation to it:—"The consumption of zinc per horse-power was obtained by carefully weighing each plate before and after every run. In the first of the above experiments (described in the report) the consumption per electrical horse-power was 10·95oz., and in the second 12·75oz. per horse-power." Presuming that avoirdupois ounces are indicated, we have here in one experiment a consumption of ·6843lb., and in the other of ·7969lb. of zinc per horse-power-hour electrical. Now, although I have stated above that the *minimum* weight of zinc corresponding to the work of one horse-power-hour, when a battery is worked under the most favourable conditions that can be devised, even theoretically, in the present condition of our electro-chemical knowledge, is ·8772lb. avoirdupois,* I will not deny that the above results have actually been obtained, but will merely point out that in the former of the experiments the mean E.M.F. in action must have been 2·95 volts, whilst in the latter it was necessarily 2·53 volts.

Mr. Ross's theory involves many facts which are true and not new, and some views that are new and not true. With the latter only have I any need to concern myself at the present time. The inventor points out that a grain of hydrogen develops in combining with its equivalent of oxygen 34,462 calories of Dulong (or the heat that would raise the temperature of 34,462 grams of water from 4 deg. to 5 deg. Centigrade), and that a volt-ampere current develops in one second ·24 of this unit of heat. Therefore, he concludes, "$\frac{\cdot 24}{34462} = \cdot 000007$ grams of hydrogen would be liberated in one second under the influence of one ampere of current. That then, as commonly understood, would be the electro-chemical equivalent of hydrogen." So that, according to Mr. Ross, physicists have been altogether in error in the experiments and calculations by which it has been determined that a current of one ampere evolves in one second, by the decomposition of water, ·00001 (or more accurately ·0000104) of a gram of hydrogen.

Let us analyse the statement of Mr. Ross. It implies that the heat evolved by the combination with oxygen of 1 grain of hydrogen is to the heat evolved by the passage of a volt-ampere current for one second as 1 grain is to $x$, the electro-chemical equivalent of hydrogen, *i.e.*, the weight of this gas liberated by unit current in unit time. Or, putting the statement in arithmetical form—

$$34462 \text{ calories} : \cdot 24 \text{ calorie} :: 1 \text{ gram} : x,$$

$$\text{whence } x = \cdot 000007 \text{ gram.}$$

Now, the electrical reader may well be excused if he fail to perceive any grounds, erroneous or otherwise, for such a statement, knowing as he does that the value of $x$ thus obtained is altogether wrong. But a little consideration will show how Mr. Ross has been led into error by what I have characterised as a dangerous amount of knowledge. *Supposing* a current of one ampere to pass through water, under the electromotive force of one volt, during one second, then the quantity of heat corresponding to one joule (or to the volt-ampere-second current) must of necessity be developed. A general formula for heat developed in a circuit is

$$C\,E\,\theta \times \cdot 24 = \text{calories (of Dulong)},$$

where C is current in amperes, E electromotive force in volts, and $\theta$ time in seconds. So that in this supposititious case, as in that of ampere current traversing ohm resistance for one second, the quantity of heat generated will be ·24 calorie. Now, if we suppose, moreover, that the resistance of the circuit is *nil*, or that the voltameter-electrodes are infinitely large, then by the principle of the Conservation of Energy the quantity of hydrogen evolved will be of necessity *that quantity in which* (and in its equivalent of oxygen) *is stored up the heat energy developed by the current*, *i.e.*, ·000007 gram, which, under the former of the two suppositions made, would be the electro-chemical equivalent of hydrogen.

Mr. Ross's ingenious mind has, no doubt, perceived this clearly enough, and we have here the explanation of what at first looks like a purely-gratuitous as well as erroneous assumption. But Mr. Ross would appear to be wholly ignorant of the facts in relation to "back electromotive force" in the theory of the electrical-transmission of energy, or of its storage in the products of electrolysis. I need not inform the readers of this paper that under the electromotive force of one volt it is impossible for any current to traverse the electrolyte water so as to evolve free oxygen and hydrogen at the electrodes. A "back electromotive force," which is close upon 1·49 volt, is generated in virtue of the affinity of the evolved oxygen for the evolved hydrogen. (This counter E.M.F. has generally been understated as 1·45 or 1·46 volt.) Now let us take a circuit in which the total resistance is one ohm, and in which a current of one ampere traverses the electrolyte water for one second. The electromotive force required is 1·49 volt to balance the counter E.M.F., *plus* one volt to urge ampere current through the given resistance, or 2·49 volts in all. The total (actual and potential) quantity of heat generated is found by the above formula to be

$$1 \times 2 \cdot 49 \times \cdot 24 = \cdot 5976 \text{ calorie (of Dulong).}$$

Subtracting from this total quantity the heat evolved by the passage of the current through the resistance proper, the remainder is ·5976 − ·24 = ·3576 calorie, which quantity is stored up in the liberated gases. And the electro-chemical equivalent of hydrogen is, necessarily, *that quantity in which* (and its equivalent of oxygen) *energy equivalent to* ·3576

* This weight corresponds to an E.M.F. per cell of 2·303 volts. The highest recorded E.M.F. with a single zinc couple, so far as I know, is 2·249 volts, obtained by Mr. Latimer Clark in the case of a cell charged with one of Delaurier's solutions.

Digitized by Google

*calorie is stored up.* Or, calling the "back electromotive force" $E_1$, and putting the statement in arithmetical form,

$$34462 \text{ calories} : \cdot 24 \text{ calorie} \times E_1 :: 1 \text{ gram.} : x ;$$

whence $x = \frac{\cdot 24 \times 1 \cdot 49}{34462} = \cdot 0000104$ grain = the electro-chemical equivalent of hydrogen.

I now come to what is practically the most important part of the present paper, viz., the demonstration of a formula which enables us with certainty to calculate either the weight of zinc consumed in a battery, when the electrical work and the electromotive force of a single cell are given; or the electromotive force of a single cell when the electrical work and the zinc consumed are given.

According to the most recent and accurately-verified data, the weight of zinc consumed in each cell of a battery per hour when current (1) is unity, is

$$18 \cdot 9578 \text{ grains.}*$$

In $n$ cells the consumption will be

$$n \times 18 \cdot 9578 \text{ grains.}$$

Still, considering the case of unit current, and calling $e$ the electromotive force of one cell, it may be observed that the consumption of zinc as above is independent of the value of $e$, provided the current be constant; that is to say, provided the resistance have the same numerical value as $e$, in which case it may be expressed by $e$. Partly to notify this fact, but mainly for an algebraic reason, I will make $\frac{e}{e}$ = unity a visible factor in the above quantity. To that, expressing $n\,e$ (the total electromotive force) as E, we have, as the equation for the weight of zinc consumed per hour with unit current

$$Zn = n\frac{e}{e} \times 18 \cdot 9578 = \frac{E}{e} \times 18 \cdot 9578 \text{ grains.}$$

When the current varies, the consumption will vary in the same ratio.

Thus we have for the total weight of zinc consumed (exclusive of local action) per hour in any voltaic battery

$$Zn = \frac{E\,C}{e} \times 18 \cdot 9578 \text{ grains.}$$

Or, in pounds avoirdupois,

$$Zn = \frac{E\,C}{e \times 369} = \frac{E^2}{R\,e \times 369} = \frac{C^2\,R}{e \times 369} \text{lb.}$$

Since $n = \frac{E}{e}$, we may write

$$Zn = \frac{E\,n}{R + 369} = \frac{C\,n}{369} \text{lb.}$$

Now, taking 746 volt-amperes as equivalent to one horse-power, the weight of zinc that will yield one horse-power-hour is

$$\frac{746}{369e} = \frac{2 \cdot 022}{e} \text{lb.}$$

Thus the total weight of zinc consumed in any zinc battery is

$$Zn = \frac{\text{H.P. hours} \times 2 \cdot 022}{e} \text{lb.}$$

Whence is obtained the formula which has been referred to as particularly useful at the present time, viz.:—

$$e = \frac{\text{H.P. hours} \times 2 \cdot 022}{Z\,n \text{ (in lb.)}}.$$

* This value is derived from the fundamental datum that 96010 coulombs react upon the gram equivalent (32·75 grams in the case of zinc).

## ON THE PHYSICAL CONDITION OF IRON AND STEEL.*

BY PROFESSOR D. E. HUGHES, F.R.S.

In a paper read before the Royal Society, May 5th, 1879, entitled "On an Induction Currents Balance, and Experimental Researches made therewith," the author showed that this instrument was extremely sensitive to all molecular changes in metallic bodies. Finding that its powers were remarkably suitable for researches upon the molecular change which takes place in iron and steel when tempered, he made with it a series of researches to determine the cause of tempering in steel. The results of these the author laid before the Institution of Mechanical Engineers (*Proc.* 1883, p. 72) in a paper "On the Molecular Rigidity of Tempered Steel." In this paper the author advanced the theory that the molecules of soft iron were comparatively free as regards motion amongst themselves, whilst in hard iron or steel they were extremely rigid in their relative positions.

The author has since widened the field of research so as to embrace all the physical changes which occur in iron and steel through chemical alloys, mechanical compression or other strains, annealing, and tempering. The results of these researches he now embodies in the present paper. Believing it necessary that we should be able to tell the physical state of any piece of iron, without destroying or changing that state, the author has sought for and tried several methods which gave any hope of success in this direction. The physical state of iron has a marked influence upon its electrical conductivity. The differences thus indicated, however, are not wide enough to be appreciated except with metal in the form of wire; and in order to perceive small changes, such as small differences of temper, we should require a wire at least 250 yards in length. The author has found, however, that by the application of certain phenomena belonging to magnetism we are enabled to perceive clearly the slightest change in the molecular structure of iron or steel, through all degrees of annealing to the finest differences in tempering, and this with pieces of any form or dimensions.

It is already known that soft iron will take a higher degree of magnetism, and retain it less, than steel; and that tempered steel retains magnetism more than soft steel. Consequently we might expect, that by the aid of an instrument which could give correct measurement of degrees of magnetism, we should be able to include all varieties of iron and steel, between the two extremes of softness as in annealed iron, and hardness as in highly tempered cast steel. The author soon found that this was not the case when pieces of iron were magnetised to saturation, or even partially so.

In a recent paper upon the theory of magnetism† the author said, "During these researches I have remarked a peculiar property of magnetism, viz., that not only can the molecules be rotated through any degree of arc to its maximum or saturation, but that, whilst it requires a comparatively strong force to overcome its rigidity or resistance to rotation, it has a small field of its own through which it can move with excessive freedom, trembling, vibrating, or rotating through small arcs with infinitely less force than would be required to rotate it permanently on either side. This property is so marked and general that we can observe it without any special iron or apparatus."

The author has found, by employing extremely feeble magnetising powers, such as a weak current of electricity only just sufficient for measurement (or the current from one Daniell cell reduced, as found best for the dimensions of the iron, by passing it through resistance coils varying from 10 to 100 ohms), that the following laws hold with every variety of iron and steel:—

1. The magnetic capacity is directly proportional to the softness, or molecular freedom.

2. The resistance to a feeble external magnetising force is directly as the hardness, or molecular rigidity.

* Paper read before the Institution of Mechanical Engineers.
† Society of Telegraph Engineers, May 24, 1883.

Digitized by Google

The author has proved this to be the case with sixty different varieties of iron and steel furnished direct from the manufacturers. And he has found that each variety of iron or steel has fixed points, beyond which annealing cannot soften, nor tempering harden; consequently, if all varieties were equally and perfectly annealed, each variety would have its own magnetic capacity, or its specific degree of value, by means of which we could at once determine its place and quality.

If in place of several varieties we take a single specimen, say hard-drawn Swedish iron wire, and note its magnetic capacity, we find that its value rises rapidly with each partial annealing, until an ultimate softness is obtained, being the limit of its molecular freedom. We are thus enabled to study the best methods of annealing, and to find at once the degree of softness in an unknown specimen.

Similarly, when we temper annealed iron and steel, we find that we can follow out each degree of temper up to ultimate molecular rigidity; and we may thus appreciate in an unknown specimen of unknown temper the degree of its hardness.

We have thus in each piece of iron or steel a limit of softness and hardness. In soft Swedish iron, tempering hardens but 25 per cent. on the scale adopted, whilst mechanical compression, such as hammering, hardens it 50 per cent. In cast steel, tempering hardens it 400 per cent., whilst mechanical compression gives but 50 per cent. Between cast steel and Swedish iron, we find a long series of mild steel, hard iron, &c., varying in their proportionate degree between the two extremes just mentioned.

The theory which the author has advanced, of molecular freedom as in soft iron, and molecular rigidity as in cast steel, fully explains all the changes which we are enabled to perceive and measure; but it is not absolutely necessary to accept the theory in order to appreciate the results. For, leaving theoretical considerations aside, we have one proved fact, viz., that the magnetic power or capacity of a piece of iron, under the influence of an external limited magnetising power, depends upon its softness; and that the retention of magnetism, when the external power is withdrawn, depends upon its hardness. The same degree of temper or annealing, upon the same iron or steel, gives invariably the same readings; but the slightest change—say from a straw-coloured temper to a blue—gives very wide differences.

*Description of Apparatus.*

The instrument which the author has constructed and used in these experiments, and which he has named a "Magnetic Balance," consists of a delicate magnetic needle suspended by a silk fibre; it is 5 centimetres in length (2in.), and its pointer rests near an index having a single fine black mark for its zero. The movement of the needle on either side of zero is limited to 5 millimetres (0·2in.) by means of ivory stops or projections. When the north end of the needle and its zero index are north, the needle rests parallel with its index; but the slightest external influence, such as a piece of iron 1 millimetre in diameter (0·04in.) placed at 10 centimetres distance (4in.) deflects the needle to the right or left, according to the polarity of its magnetism, and with a force proportionate to its magnetic power. If we place on the opposite side of the needle, and at the same distance, a wire possessing absolutely the same polarity, of similar name and force, the two balance each other and the needle returns to zero; and if we know the magnetic value required to balance the first piece of iron we know the magnetic value of both.

The iron (which may be in the form of wires, rods, bars, plates, or any shape or size desired),* is placed at a fixed distance (preferably 10 or more centimetres) (4in.), resting against a fixed brass stop. The centre of the iron should be in a line with the centre of the needle, and it should be placed at right angles to the needle, lying horizontally east and west, so as to be free from the directing influence of the earth's magnetism.

* The smallest rods yet tested have been fine sewing needles, and the largest bars of 5 centimetres (0·2in.) diameter, 1 metre (3ft. 3⅛in.) long.

The compensator, placed upon the opposite side of the needle, and at a distance of 30 centimetres (12in.) consists of a powerful steel bar-magnet, 3 centimetres width, 1 centimetre thick, and 6 centimetres long (1·18 × 0·4 × 2·36in.). This turns upon its axis, carrying with it the pointer, to indicate its degree of angular deplacement on the graduated circle. Generally this bar-magnet is parallel with the needle, the pointer of the compensator and the needle being at zero; but when we wish to measure the amount of magnetism in the piece of iron, the bar-magnet is made to pass through an angular displacement necessary to balance this force, and its index readings on the graduated circle are taken as the comparative values.

In order to magnetise the iron, if required, by an electrical current, a coil of insulated copper wire is placed near the brass stop, the iron then becoming the core of an electromagnet.

Now as this coil, independently of its iron, acts upon the needle, this action must be balanced by an opposing coil on the opposite side. The position and power of these two coils can be adjusted by means of the lever, which allows us to find a position where the two coils completely neutralise each other. If we introduce iron in the coils on either side, the balance is destroyed, and we have solely the magnetic influence of the iron core, whose value we find by an equal opposing magnetism brought into play by the rotating magnetic compensator.

A reversing key serves to change the direction of the current, and thus any difference between north and south polarity in the iron core can be observed. One Daniell cell is all that is required as a battery; but great care must be taken that its electromotive force is a constant, otherwise all variations in the battery would be read as variations in the quality of the iron itself; and we need in addition a series of resistance coils from 10 to 100 ohms, in order to reduce the current sufficiently to bring the whole series, from soft Swedish iron to cast steel, into range. Separate and finer determination can then be separately made by an extremely weak force for soft iron, and full or increased battery power for tempered steel. A series of different sized coils is necessary, whenever we vary greatly the diameter of the core. The first size, with an internal core-opening of one centimetre (0·4in.), will test bars and rods of wire, from one centimetre diameter to the finest needle; but for larger bars, plates, &c., coils must be used which allow free passage for the iron into the core. Great care and some practice is necessary in the use of the instrument, so as to ensure that the iron is placed in a neutral field; but when we have really obtained the necessary conditions we can take several readings in a single minute, with an invariable result for the same kind of iron.

All irons and steel have some traces of remaining magnetism; it is therefore necessary that a double reading (north and south) should be taken by means of reversed currents. In this case the quadrant is divided into 360° on each side of zero; and the total value of north and south polarity added together is that given in the following tables of magnetic capacity.

Several methods of observation can be employed with the magnetic balance, the usual one being that already described; but there are many others, such as magnetising all specimens to the same value and noting the amount of current required. We may also observe the remaining magnetism after the cessation of the current; the influence of a weak current after the passage of a strong, &c. Many of these methods give interesting facts, particularly useful to those making researches upon the cause of magnetism.*

By means of this instrument the author has tested sixty brands of iron and steel, mostly in the form of wires. A wire one millimetre diameter and ten centimetres long (0·04in. and 4in.) was the standard size used, as we can more readily temper small wires than large rods.

* The author has not patented this instrument, giving it freely to the scientific and manufacturing world.

## OVERHEAD WIRES.

Notwithstanding the circumstance that one or more test actions are before the courts to determine the powers of local vestries in relation to overhead telephone wires, the newspapers continue to discuss the question freely, and to pronounce their own judgment upon it. That judgment is, with one exception, so far as we know, unanimous, and is substantially this: That if the vestries have no power to control what is above the streets, the sooner they obtain such power the better; but that, with fullest control over what goes under and upon the thoroughfares, it is incredible that there should be none for what goes over them. This incredulity grows stronger every day as the growth of the overhead system goes on apace with a rapidity which may be observed from day to day in the heart of the City of London. People are beginning to ask, if the occupants of the upper stories of the City were to cast their clothes-lines from side to side, and hang their garments out to dry across the public highway, whether in this case no authority exists with powers sufficiently exalted to reach the offenders? The question may seem too ridiculous to need an answer, but so, indeed, does the question of overhead wires. No pedestrian can pass along such thoroughfares as Cheapside, Queen Victoria-street, Threadneedle-street or Cornhill, to say nothing of Fleet-street or the Strand, without mentally asking when the limits of patience will be reached; but he will have no sort of doubt that the law has been exceeded already, for the simple reason, if for no other, that the nuisance must very soon become unbearable. As matters stand at present, any and every street in the metropolis is liable to be covered over, first with a dense cobweb of wires, and afterwards with a huge gridiron of them, just as Coleman-street, E.C., for example, is at this moment. If any British judge or jury would visit this and other streets similarly obscured, the legal difficulty—if there is one—would be greatly simplified. Legal questions of an entirely new character, arising out of novel conditions, are frequently determined by the exercise of common sense, and common sense in this instance would at once declare that powers specially given to guard public safety and convenience must be deemed to cover anything that manifestly threatens them.

The exception to the unanimity above alluded to is the *Saturday Review*, which, while admitting the danger and the nuisance of overhead wires, magnifies the difficulties in the way of removing them, and suggests fresh legislation on the subject. Legislation, after our experience of the Electric Lighting Act, is not a very promising remedy, even if it were proved to be necessary; and as to the engineering and electrical difficulties, they are not nearly so great as our contemporary seems to imagine. What it says about the effects of induction is all very true supposing it were necessary to put telephone wires side by side with telegraph wires. Even this could be done, as the Post Office has done already, by doubling the telephone wire; but there is no such necessity, and the fact is known perfectly well. The simple truth is, the telephone companies and the news agencies have erected their wires in the cheapest manner possible, and carried them by the cheapest routes; and now that the public are complaining that this cheapness has resulted in much nastiness the proprietors demur to any alteration whatsoever, on technical grounds which have no real existence, and on financial grounds which they ought to have considered long ago. Hence this cry for legislation, which would, it is shrewdly conjectured, whitewash all past offences and "regulate" in an agreeable fashion all future extensions.

It is naïvely remarked by the advocates of fresh legislation that it would be a great pity, however, if legislation took the form of forcing the Postmaster-General and the telephone companies to be at the cost of placing all their lines underground. But nobody proposes anything so unreasonable. The two systems are not to be compared. As a fact the Government wires in the metropolis are mostly underground already, whereas the private companies' wires are all overhead, and it is these latter that are the offenders. It would subject the Postal Telegraph Department to no serious cost to remove the comparatively few remaining overhead wires belonging to it in towns; and as regards its railroad and highway wires no question at all is raised. In towns it has generally behaved in a conciliatory manner, and often with expensive deference to the tastes of the inhabitants. No well founded complaints ever arose or are likely to arise from the extensions of the Postmaster-General, though it is true that the prejudice against overhead wires—created solely by the wanton and insolent aggressiveness of telephone companies—has recently led to vexatious opposition to the erection of telegraph wires, even in suburban districts. The chief and, indeed, the only offenders are the private companies,

Digitized by Google

who, presuming on the acknowledged service they were doing the community, have carried their wires in such numbers across crowded thoroughfares, and in such directions, as suited their pockets best, regardless of the certain consequences that would follow if their enterprise were patronised to the extent they expected it would be. This being the case, although it would be a "pity" to compel them to put their wires underground, or at any rate out of sight, the pity is solely the companies' affair, for they are certainly entitled to none from the general public, whom they have deliberately and shamefully outraged.

Our contemporary has a good deal to say about the danger of overhead wires, and talks learnedly about the factor of safety, which in the case of housetop wires is systematically minimised. "There is no reason," says the *Saturday Review*, "why a telegraph wire should be more dangerous than a railway bridge crossing a road." What is here meant is that you could, if you liked, make a telegraph wire, or a thousand telegraph wires, crossing a street as safe as any railway bridge. But what if we object to them being there at all? In the matter of a railway bridge the public has a voice in the matter; it may impose conditions, and, for reasons shown, may prevent its construction. The constructors of telephonic systems consult nobody, offend most, and endanger many, by simply slinging their wires and cables across the street with the smallest practicable factor of safety for themselves, the least possible regard for other people, and no regard for public decency whatever. We say public decency, for, after all, it comes to this—the utterly indefensible vandalism which has characterised the business from the very beginning. It has proceeded on the principle that public buildings were made for telephone wires, not telephone wires for the occupants. Danger there certainly is, but it is not imminent, and it may even be averted by good luck or more wakeful supervision. But the eyesore is a tangible reality, and a never ceasing cause of offence. When the citizen looks upwards and timidly asks, Are not those wires very, very dangerous? he really means that they are, they really are, very ugly; and the only interrogatory in his mind is, Are they not superfluously and gratuitously offensive? To this there is but one answer, the answer, namely, that the wires and cables which are now rapidly shutting out daylight and destroying what little beauty is still left us are an unredeemed nuisance, which calls for speedy abatement, and which, if it had its deserts, would be summarily swept away.

CURRENTS PRODUCED BY IMMERSION AND EMERSION.—Krouchkoll has contributed a note on this subject which is published in a recent number of the *Comptes Rendus* of the French Academy of Sciences. He finds that when one of the electrodes of a cell is withdrawn from the liquid a current is produced. When the electrode is plunged into the liquid a current is produced which is in opposite direction to that produced by movement of the electrode in the liquid; the current caused by withdrawing the electrode is, on the other hand, in the same direction as that produced by movement of the electrode. These immersion and emersion currents are produced when the metal passes from an insulating to a conducting liquid, as well as when the metal passes from the air into a liquid. The electromotive force produced by the motion is analogous to that produced by polarisation; it is destroyed by solutions of salts of the metal of which the electrodes are composed, so that if the saline solutions are sufficiently strong, no current is produced by moving the electrode. These phenomena can be explained by Helmholtz's hypothesis of double layers of electrical tension.

## CORRESPONDENCE.

### THE LALANDE-CHAPERON AND BENNETT CELLS.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: In your number for last Saturday, p. 219, in a short notice of my communication made to the Glasgow Philosophical Society, on the 9th inst., on "Measurements made at the Vienna Exhibition, of the current yielded by the voltaic elements of Lalande and Chaperon," I am reported to have said that "the battery . . . was superior to that of Bennett." This is only a part of what I said; a part which, appearing alone, wouldbe doing an injury to Mr. Bennett's excellent cell. I said that the Lalande-Chaperon cell was inferior to the Bennett cell in electromotive force, but was superior to it (and to every other kind of voltaic element hitherto known to me) in its very remarkable capacity for giving very strong and steady currents from plates of moderate area. I have at present a cell of quite moderate dimensions which gives me a current of 100 amperes; a result most valuable to me for work I am at present occupied with in the way of graduating galvanometers for very strong currents. I hope soon to send you a very short report of the Vienna measurements, which were kindly made by Messrs. Abdank and Skrzynski, at my request, on the currents given by the new voltaic element when set to work through small external resistances. Meantime I may remark that the relation of this cell (amalgamated zinc, caustic potash, and copper "scale"—oxide of copper scraped off sheet copper in the process of rolling—strewed on the bottom of an iron containing pan) to the Bennet cell (amalgamated zinc, caustic potash, porous cell separator, iron filings, and iron plate electrode) is very remarkable. The Bennett cell has a potential of from 1·2 to 1·3 volt when working through very great external resistances. The Lalande-Chaperon cell I have found, when first set up, to give very nearly one volt on very great (practically infinite) external resistances. After it has worked for a considerable time through small external resistances, its potential, which recovers slowly when the work is stopped and the cell is put on to an electrometer or galvanometer of very great resistance, does not come back to the one volt. In specimens of the Lalande-Chaperon cell of several different sizes, on which I have at present made trials, the potential has come back to from ·82 to ·94 volt.—Yours &c.,

WILLIAM THOMSON.

The University, Glasgow, January 21, 1884.

### THE AMPERIAN CURRENT HYPOTHESIS.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: Mr. FitzGerald has, I think, somewhat mistaken the purport of my former note on this subject. I need hardly say that I do not propose to dispute such a fact as the polarity of a solenoidal currents; but I merely question whether the molecular currents required by the amperian theory (as it is usually stated) have any real physical existence.

It seems to me that there is a very considerable difference between the idea of a miniature voltaic current endlessly circulating around a (homogeneous?) molecule, and the, to say the least, more intelligible conception of the molecule having a static charge. Not to mention other obvious distinctions, one case, as Professor Ayrton remarks, requires a continuous expenditure of energy, while the other is free from such a fatal objection. In speaking of the former hypothesis (under its usual title of the "amperian current theory") I expressed no opinion on the latter. But I may now say that I do not quite see how to reconcile it in detail with recent experiments, and it is in the hope that Mr. FitzGerald may be induced to deal with the question in detail that I venture to offer the following "notes and queries" upon this theory.

It is probably my own fault that I was not previously

Digitized by Google

acquainted with the very interesting experiment by which in the year 1868 Mr. FitzGerald showed that the rotation of a charge produces magnetic polarity.

I cannot, I think, be wrong in assuming that the polarity changes sign with the direction of rotation. Will Mr. FitzGerald be good enough to say whether the polarity is also reversed when the *sign of the charge* is reversed? If the direction of polarity is independent of the sign of the charge, the result would not seem to accord with the analogous case of the polarity of a solenoid. On the other hand, if the direction of polarity varies with sign of charge, as well as with direction of rotation, it is clear that, with a charge of one sign (either + or else —), a given polarity will require a rotation opposed in direction to that of the "amperian currents," or to the current in a solenoid of the same polarity. It occurs to me, however, that possibly if a charge of *one sign only* is consistent with magnetic phenomena, then a charge of opposite sign may be connected with the phenomena of diamagnetism. I mention the idea for what it is worth. Very probably Mr. FitzGerald has already treated the question experimentally.

With regard to Mr. FitzGerald's recent paper on the Gramme ring, to which he makes reference in his letter, the "amperian theory" is always admitted (as I said in my first note) to be a good working hypothesis, and in Mr. FitzGerald's hands it leads to a logical and consistent account of the Gramme machine. But this can hardly be held to demonstrate that molecular currents are the *vera causa* of magnetism.

I note that in the third paragraph two instances are given in which the results of induction are different from what Mr. FitzGerald thinks "the average electrical *savant*" would expect to find. It is then remarked that "the mischievous explanation of magneto-electric induction by the cutting of lines of force has much to do with the mystification which is prevalent in relation to these phenomena." But it seems to me that the explanation of these cases by the "lines of force" method can at least claim to be more simple and straightforward than that offered or implied by Mr. FitzGerald in his next paragraph. It is only necessary to consider the relative rate at which, in the part of the field under consideration, the number of lines of force cutting the coil undergoes variation.

I am glad to see that Mr. FitzGerald promises "on another occasion to refer to the erroneous explanations" of the Gramme ring "hitherto put forward." Might I venture to draw his attention to that given by Mr. H. Cunninghame, originally published in his "Law of Electric Lighting," in 1883. A criticism of this paper cannot fail to be of much interest.

Not wishing to occupy too much of your valuable space, I will postpone until next week anything else I may have to say in reply to Mr. FitzGerald's letter.

Permit me, however, to say that as I am indebted to Mr. FitzGerald for very much valuable information, and especially as his long-continued study of these questions and his position in the scientific world entitle any opinion of his to the greatest respect, I can only regret that I should have the misfortune to entertain any views differing from his own. But the circumstance will not, I trust, occasion him any excessive mental perturbation.—Yours, &c.,

Liverpool. W. H. SNELL.

## PROVISIONAL PROTECTION.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: Can you inform me through the medium of your valuable journal if it is allowable to put the word "patented" upon articles which have received provisional protection?—Yours &c., F. L.

Manchester, Jan. 21, 1884.

[The patent agent is the best authority to consult on legal questions relating to patents. Our own opinion would be, however, that the designation "patented" cannot be used until the patent is obtained.—ED. *E.*].

## THE GRAMME RING.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: It has struck me while reading through the correspondence on the above that the so called lines of force theory, which Mr. FitzGerald so heartily despises, offers a much more easily understood explanation of the action of the Gramme machine than that offered in his much involved and lengthy contribution of some weeks back. The difficulties which Mr. FitzGerald has encountered in explaining the action of magneto and dynamo machines in terms of the addition and subtraction of lines of force enclosed by the rotating coils I am at a loss to understand, as I know of no machine whatever in which the action cannot be expressed in these terms. It requires very little mental effort to remember that the addition to a coil of lines of force coming from a N pole causes a current to flow in a direction opposite to that of the hands of a watch, and when this fact is firmly grasped, we have at once the clue to the following, always remembering that we are looking on that side of the coil which is the nearer to the magnet:—

(*a*) Adding N lines of force { Current flows in opposite direction to hands of watch.
(*b*) Subtracting S „ „ {
(*c*) Adding S „ „ { Current flows in same direction as hands of watch.
(*d*) Subtracting N „ „ {

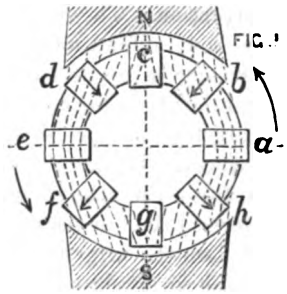

FIG. 1

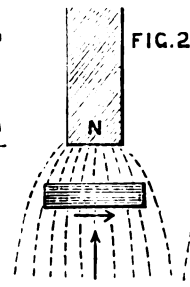

FIG. 2

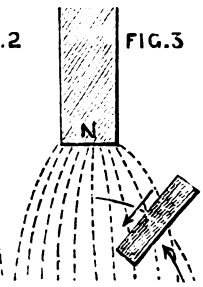

FIG. 3

The annexed sketch, Fig. 1, pretends to explain the application of these facts to the action of the Gramme machine. N and S are north and south poles respectively, *a b c* and *d* being coils. The machine rotates in the direction of the large arrows, and we will suppose that the spectator is stationed in front of the approaching coil. If a coil starts from *a* towards N, manifestly lines of force coming from a north pole will be subtracted from the coil, and the current will be seen to flow in the direction of the hands of a watch, as at *b*. After the coil passes *c*, lines of force from a S pole will be added to the same face of the coil; the current will therefore continue to flow in the same direction, as at *d*. When the coil passes *e*, lines of force from a S pole are being *subtracted*, the current reverses and flows in the opposite direction to the hands of a watch, as at *f*. After the coil passes *g*, lines of force from a N pole are being added to the same face of the coil, and the current continues to flow in the same direction until the coil arrives at *a*, when the same cycle is re-repeated. The explanation is simple and complete.

Mr. FitzGerald seems to imply that because the current in a coil flows now in this direction, now in that, when approaching say a N pole, it is impossible to explain the action on the "lines of force method," but really the *approach* has nothing to do with it. The question is, are lines of force added or subtracted? In Fig. 2, if a coil approaches a N pole end on, the current will flow as shown by the arrow from left to right, but if it approaches in a circular path, as shown in Fig. 3, the current will flow in exactly the opposite direction—and why? Because in the first instance lines of force are being added, whereas in the second case they are being subtracted.—Yours, &c., E.

## MANUFACTURE OF INDIA RUBBER STAMPS.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: Can any of your numerous readers inform me where I can purchase a machine for the manufacture of indi a rubber stamps, and the probable cost of same?—Yours, &c·,

Bristol, Jan. 17, 1884. J. R. R.

Digitized by Google

## SECONDARY BATTERIES.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: If Mr. Desmond G. FitzGerald will read the "Recherches sur l'Electricité" a little more carefully he will, we think, see that the quotation he gave has nothing whatever to do with the working, or general use, of the batteries, but relates to the process of "formation" only. Any one who has had any experience in "forming" and working Planté cells knows that the oxidation, and, consequently, the capacity for storage, does not increase unless the cells be first overcharged and then reversed. This overcharging and reversing may be carried on to any extent, at the risk, of course, of endangering the life of the cell. But, to show how far the process of formation may be carried with safety to the life of the plates, we give the following extract from M. Planté's writings:*—"*If only half of the thickness of the positive plate were completely transformed into peroxide of lead, a very great quantity of energy could be stored, more than* 200,000 *coulombs per kilogramme of lead in the cell* (see *Comptes Rendus*, August, 1882, T. XCV., p. 418).

Now, the Elwell-Parker (Planté) battery plates are only converted into peroxide and spongy lead respectively, to the depth of one-fifth of the total thickness of the plates, in order that a cell containing 40lb. of lead may possess a capacity of 120 ampere hours. A deeper "formation" than one fifth seems useless, except in very few cases, because the rate of charge and discharge cannot be increased as the capacity increases; on the contrary, some care is required in charging and discharging plates that are very deeply "formed."

We have a letter from M. Planté in which he confirms our statement regarding the long life of the cells as follows:—(Translated) "If you think well to answer them, you can say, in reply to the first letter, that you have seen in M. Planté's laboratory at Paris some secondary cells, the plates of which are *twenty-four years old*, and which have been used frequently during that period, either for experiments or for galvano-caustic operations, and of which the positive plate, one millimetre thick only, partially transformed into peroxide of lead of a crystalline nature, possesses, nevertheless, sufficient metallic support in the interior to enable the cell to still work in a very satisfactory manner" (January 19th, 1884).

He goes on to say that "It is evident that, if the thickness of the plate were less, it would be converted into peroxide to a proportionately greater extent; and that if, on the other hand, it were thicker, say by one or two millimetres, it is certain that it would possess sufficient metallic support to stand a very prolonged usage."

Consequently, although we cannot, of course, prove that the Elwell-Parker Planté battery will last twenty-three years—and we certainly did not state anything of the kind—there is every reason to believe that, with ordinary care, they will last a very long time, and even the most gross overcharging and rough usage has failed to have any noticeable effect upon plates now subject to it for some twelve months.

We are interested in hearing what experiments Mr. FitzGerald has carried out, assisted by the staff of skilled electricians, but we beg to suggest, with all due respect to Mr. FitzGerald's superior knowledge, that he might have arrived at something much more valuable had he been assisted by a few skilled chemists as well as electricians, as he would not then have troubled to try the use of acetic acid in hastening the formation of a Planté cell.

It is a property of acetic acid to attack lead in preference to other metals, consequently there would soon be uncommonly little pure lead left in plates subjected to a treatment of acetic acid.

Nitric acid, on the other hand, attacks the *impurities* of the lead plates *in preference to the pure lead*, and the "great discovery" (we still think it deserves the title) consisted, not in the fact that nitric acid corrodes lead plates (which every schoolboy knows, or ought to do), but that nitric acid was beneficial in the highest degree for creating a condition of plate most suitable to receive the action of the electric current in Planté batteries. The plates appear quite as smooth when drawn from the nitric acid bath as they were before immersion. Mechanical roughening by means of sand-blast, &c., has not an effect at all analogous, and the fact that M. Planté, after more than twenty years devoted to the study of his batteries, and after trying many chemical processes for hastening the formation of the plates, with more or less success (see *Les Mondes*, August 26th, 1873, T. 31, p. 743, July 25, 1881, &c.), thought nothing worth a patent until he arrived at the nitric acid process, points forcibly to his great opinion of its value—compared to other chemical processes.

If Mr. FitzGerald be successful in "dissolving out" one of the components of a lead alloy, he will be cleverer than most electricians, or chemists either.

Again, referring to his concluding quotation, it is perhaps more satisfactory to any of your readers interested in the question to give the whole of the paragraph to which Mr. FitzGerald refers. He did not tell us where to find it, but, as we almost know the book by heart, we remembered that it was in the chapter upon the "formation" process, page 54, and is as follows:—"On laisse alors le couple secondaire au repos pendant huit jours, et on le recharge en sens inverse pendant plusieurs heures, sans faire, le même jour, de nouveaux changements de sens. Puis, on porte, peu à peu l'intervalle de repos à quinze jours, un mois, deux mois, &c., et la durée de la décharge va sans cesse en augmentant. Elle n'a d'autre limite que l'épaisseur même des lames de plomb. La lame positive, si elle est mince, finit par être transformée pres-que entièrement, avec le temps, en peroxyde de plomb à texture cristalline. La lame négative se trouve peu à peu formée, jusqu' à une certaine profondeur audessous de sa surface, de plomb réduit, grenu et cristallin. Il n'est pas toutfois nécessaire de pousser la preparation électro-chimique des couples secondaires jusqu' à cette transformation complète de la nature physique et chimique des lames; car les couples finissent alors par acquérir un plus grande résistance et exigent plus de temps pour être chargés."

With regard to the cunningly-worded letter from the Electrical Power Storage Company (Limited), it suffices to say that nitric acid is *not even mentioned* in Mr. John S. Sellon's patent of the 10th September, 1881, and the general manager now does not appear to know what the chemical effect of nitric acid upon lead plates consists in. As for claiming *any process*, chemical or mechanical, we can only refer the company to the various publications of Gaston Planté.

In conclusion we must make, in reply to a statement in the latter of the two letters, the remark that the Elwell-Parker battery is purely a Planté battery in electro-chemical formation, but the entire credit for the successful mechanical construction of the large cells now in general commercial use is due to Mr. Thomas Parker.—Yours, &c.,

THE WOLVERHAMPTON ELECTRIC LIGHT, STORAGE, AND ENGINEERING COMPANY.

January 23, 1884.

## THE CAUSE OF MAGNETISM.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: I observe that Mr. FitzGerald states that he published in 1868 a proof that the rotation of a body electrically charged produced magnetic polarity. As this proof is usually accredited to Professor Rowland, who in 1876 made the expe-

* We translate from the French for the benefit of any of your readers who have not the advantage, like Mr. Desmond G. FitzGerald, of understanding that language.

Digitized by Google

riment in Helmholtz's laboratory, it would be interesting to learn the details and exact results of Mr. FitzGerald's experiment.—Yours, &c., SUBSCRIBER.

Jan 19.

[We hope to give the article referred to by Mr. FitzGerald in our next issue, so that "Subscriber" and others interested in the question will see how far, if at all, the experiments of Prof. Rowland were forestalled.—ED. *E.*].

## ANGLO-AMERICAN BRUSH ELECTRIC LIGHT CORPORATION.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: As an impression seems still to exist in some quarters that the Anglo-American Brush Electric Light Corporation (Limited), confine their operations, almost exclusively, to the arc system of electric lighting, in connection with which their name is so generally known, I think this an opportune time, when the corporation is issuing a new-priced catalogue of its various machines and apparatus, to point out that so far from this being the case, the corporation has always most fully recognised that the incandescence system and the arc system has each its proper field of development. The operations of the corporation were at first and in its initiatory stages naturally directed chiefly to installations of arc lighting, for which the Brush machine has proved itself so pre-eminently adapted, and which pre-eminence it has maintained up to the present time; but it must be remembered that this was only because incandescence lamps had not in those days attained to a degree of perfection which rendered their large employment practical, neither was the public mind ripe for the introduction of domestic electric lighting.

The corporation, however, fully appreciated the large development that incandescence lighting was destined to make, and recognised that it must be prepared to meet the demand for this class of apparatus which the growing interest of the public in the advantages of electric lighting would inevitably ensure. The corporation had to secure not only the production, on a large commercial scale, of incandescence lamps which should be durable, uniform, and of good appearance, but also to provide a dynamo to answer all the requirements of incandescence lighting as perfectly as the Brush dynamo answers those of arc lighting, and which should be cheaper to buy than the Brush machine as adapted for incandescence lighting. The result of the measures early undertaken by the corporation has been that it has now for a considerable time been in possession of an incandescence lamp which fulfils all the above requirements in a high degree, and is believed to be by far the best lamp in the market, and as the result of a long series of carefully conducted experimental work, the corporation has more recently been placed in possession of a specially designed dynamo for incandescence lighting of high efficiency, and suitable in every way to meet the large demand that has arisen for such machines.

This dynamo in the larger sizes in which it is made gives a return in electrical energy of as much as 96 per cent. of the mechanical energy expended on it, it embodies the electrical patents of Schuckert, Mordey, and others, which are the property of the corporation, and as it appeared to the corporation that it was desirable to give their new machine a distinctive name, they have called it the "Victoria" dynamo. These machines are made of several sizes, and of various electrical capacities, the smallest being that capable of maintaining twenty lamps of 10 candle-power (actual), and the largest at present designed is capable of maintaining 1,600 lamps of 10 candle-power (actual).

Inasmuch as the unparalleled success which has attended the Brush machine has been due not only to its electrical efficiency, but also to its great perfection as a piece of mechanical workmanship, the corporation, in working out the details of its more recent Victoria machine, has devoted much care and attention to its mechanical as well as to its electrical details, and has thus produced a machine which in the excellence of its construction and design is, they believe, unequalled.

A considerable demand has lately arisen for slow-speed dynamos. This is entirely due to the fact that many of the machines at present before the public are so faulty in their mechanical construction, that, at the high speed at which they have to be run to do their work, they soon wear out, the bearings become abnormally hot, and excessive destructive sparking occurs at the commutator and brushes. It therefore obviously became necessary to keep down the speeds of these dynamos, and where slow speed machines were required, large machines, running under their normal speed, were necessarily supplied to do the work of smaller ones.

Such serious defects as those above enumerated entail great loss of power and shorten the life of the machine. For the Victoria dynamo it is claimed that the material is so judiciously employed, that all iron work is so made use of both magnetically and mechanically, and the frames so braced together, that there is no racking. The bearings are made very long and true, to avoid wear and heating, loss of energy is avoided both by making the commutator and all the electrical fittings large and massive, and sparking at the commutator is reduced to a minimum by the arrangement of the pole pieces. Simplicity is further obtained by means of the patented system of connecting the bobbins, by which means no more than one pair of brushes are ever required.

In this dynamo all undue heating of the armature consequent on the free circulation of induced currents in the armature core itself, is avoided. This is brought about by suitably laminating the core, insulating the parts, and for further protection against these injurious influences, a free natural circulation of air through the laminated core is secured.

Attention to the above points distinguishes the Victoria machines from any other in the market, with the result that they will bear to be run *continuously* at their advertised speed and power, and after a twenty-fours' run the armature is as cool as the field magnets.

Further, it should be noted that although the corporation is opposed to the exceptionally slow speeds which have been lately advocated as alone compatible with economy, yet the speeds of its machines are distinctly moderate as compared with those of other makers, so that when it is called upon for machines to be driven directly and to run at an exceptionally slow speed, it is enabled to supply these without largely increasing the weight and dimensions.

The following is a list of such special compound-wound slow-speed machines which the corporation manufacture, more especially for ship lighting and for direct attachment to the Brotherhood, Westinghouse, Willans, Tower, or other suitable type of high-speed direct-acting engine, adopted by it for the normal speeds:—

Special Compound-wound Slow speed Victoria Incandescence Dynamos.

| Type of Machines. | No. of 10 C.P. lamps in parallel. | No. of 20 C.P. lamps in parallel. | Revolutions per minute. | Prices. |
|---|---|---|---|---|
| $B^2S$. | 60 | 30 | 700 | £80 |
| $D^2S$. | 140 | 75 | 650 | £150 |
| $D^2LS$. | 200 | 100 | 600 | £175 |
| $E^2S$. | 400 | 200 | 450 | £275 |
| $H^3S$. | 800 | 400 | 450 | £475 |
| $M^4S$. | 1600 | 800 | 400 | £950 |

The system of compound winding adopted by the corporation is, I venture to submit, perfect, since a dynamo running at a constant speed *will run one lamp with the same degree of incandescence as it will run the maximum number of lights for which it is made*; in other words, any number of lights can be turned on or off without any regard whatever being paid to the dynamo machine, which continues to run at its normal speed, while the power absorbed by the dynamo remains at all times practically proportional to the number of lamps in action.

For the normal sizes of Victoria machines I would refer

Digitized by Google

you to page 29 of our illustrated catalogue. In incandescence lamps a slow but sure advance has been made within the last year in perfecting the details of the manufacture so as to insure regularity and durability. The corporation manufacture lamps of a great variety of powers, but make a special point of their 10 candle-power lamps, which they claim to be unrivalled in the above respects as well as in appearance.

With regard to the Brush arc machines, they still retain their high position as the only dynamo in the market proved to be capable of running a large number of lamps in series. Mistaken and injurious comparisons are sometimes made with regard to its first cost compared with that of dynamos of other systems, but such can only be made with even a show of justice by ignoring the economy accomplished by the Brush dynamo in the *first expense for insulated leads.* If this item is included it will be found that the Brush machine is the cheapest as well as the best.

The Brush arc lamp has also experienced considerable improvement within the last year, in appearance and also in some of the smaller details of its fittings. In cheapness, durability, and simplicity it still keeps its unrivalled position. Where great steadiness of light is of more importance than economy, the corporation advocates the use of soft cored carbons.

There is a growing demand for the electric light for lighting up large halls, churches, and concert rooms. For such application *absolute* steadiness is essential, and as in these positions the lamp is far less liable to rough usage than in street lighting or other exposed situations, the corporation recommends the employment of its new Rachet lamp for such installations.

The corporation also invites attention to its lanterns, both hanging and for fixing on posts, which are of very handsome patterns, and suitable for exposed situations at the seaside and elsewhere.

I also take this opportunity to inform you that the attention of the corporation has been directed to the question of the advisability of providing periodical inspection of the dynamos and lamps which it has supplied, and having full confidence in obtaining the support of its customers for this purpose, the corporation is at present engaged in maturing the necessary arrangements for carrying this scheme into operation.

In conclusion, I am authorised to inform you that not only on this point, but also on all others which may be of benefit in assuring the satisfactory working of the electric light, the corporation is most anxious to consult the convenience and advance the interests of its customers.—Yours, &c., FRANK WYNNE, Manager.

The Anglo-American Brush Electric Light Corporation (Limited), Belvedere-road, S.E.

[We have been asked to give publicity to this letter, a copy of which has been sent to the shareholders of the corporation, and we gladly do so to show that the corporation is endeavouring to march with the times.—ED. *E.*]

## RUNNING TWO DYNAMOS TOGETHER.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: I am much obliged to you for inserting my letter, under the heading "Running Two Dynamos Together." The difficulty may be solved, perhaps, before I get your next issue. But, to save time, should any of your readers kindly think fit to take up my case, I should say that my dynamos are series wound of equal power (nominally), and also that when coupled up for quantity to the lamps they seem hard at work, though they are of no use as far as lighting is concerned. My own idea is that they are simply working against each other, though why they should do so I cannot make out. Anyhow, they give the engine as much to do as when each is running on its own account and lighting its moiety of lamps. I should add that the E.M.F. of one seems slightly higher than that of the other.—Yours, &c.,

Bath, Jan. 21. A CONSTANT READER.

## THE DAVY MSS.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: Allow me to correct a slight mistake regarding the above made by your reporter on page 234 of last Saturday's *Electrician.* The volume of MS. papers, letters, &c., relating to Edward Davy's early and important discoveries in electric telegraphy was presented to the Society of Telegraph Engineers and Electricians by Dr. Henry Davy, of Exeter, a nephew of the veteran scientist, and to him, therefore, and not to me, were the thanks of the society awarded.

It ought to have been mentioned at the same time that Dr. Davy had presented two of the Daniell cells with which his uncle had performed his telegraphic experiments 1836-9. These interesting relics were discovered by me in the manner described in your issue of July 21, 1883, and, with the no less interesting volume of MSS., may now be seen in the library of the society.

It is gratifying to learn "that the council have under consideration how to deal with Mr. Davy's claims." Mr. Davy's fellow-colonists have long ago solved this problem for themselves (1) by electing him with acclamation a life honorary member of the Royal Society of Victoria, and (2) by appointing a committee to devise the best means of doing him public honour. The telegraph engineers of England cannot do more, and they ought not to do less.—Yours, &c.,

London, January 21, 1884. J. J. FAHIE.

## A STANDARD OF LIGHT WANTED.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: I should be extremely obliged if any of your readers could give me the names and description of other standards of light than that of the standard candle (Sugg's), also their comparative accuracy as compared with the unweighed method by the standard candle. I have occasion to measure illuminating powers between 5 and 100 candle-power, and have daily used for the past two years the ordinary standard candle of Sugg unweighed. This method, even with constant practice and attention, is not delicate enough; anything requiring more practice and attention than a "candle standard" would be useless, as on an average over 150 tests are made per diem.

Any form of standard of light suiting the above requirements, no matter how expensive, would be a great boon, especially to incandescent lamp manufacturers.

Having personally made thousands of tests of every make of incandescent lamp, and, using the maker's actual E.M.F.'s given for a particular candle-power, I find the variations so great that the lamps of the different makers, and even those of our own make, tested with the same "candle standard" from day to day, would, when hung together, be found to burn some to excess, and others again giving only 7 or 10 candle-power.—Yours, &c., A CONSTANT SUBSCRIBER.

## THE ELECTRIC SUN LAMP AND POWER COMPANY.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: Having seen a statement in one of the electrical papers that Mr. Paget Higgs was about to be appointed manager of the Electric Sun Lamp and Power Company, I shall be glad if you will allow me to state that this is quite incorrect.—Yours, &c., J. REEVE, Secretary.

St. Margaret's Offices, Victoria-street, Westminster, Jan. 19, 1884.

CABLE COMMUNICATION WITH HOLLAND.—Lord Granville has informed the Dutch Government, in reply to their representations, that the Postmaster-General has under consideration the question of the defective telegraphic communication between England and Holland, and that a speedy decision may be looked for.

## FLETCHER'S WATCHMAN'S DETECTOR.

Since we described Elliott's Detector, Vol. VIII., p. 11, other apparatus has been devised for the same purpose. One of the latest and simplest forms is that designed by Mr. Fletcher, the telegraph engineer of the North Western Railway, and manufactured by Messrs. Blakey, Emmott, and Co., of Halifax. This system requires only one wire, but, on the other hand, a piece of apparatus is required at every point to which it is desired to show that the watchman has duly gone. The principle is a registering apparatus, and a circuit broken at various points. The watchman visits and completes the circuit at each point, and on completing the whole circuit a signal is transmitted and registered. In making the signal the circuit is broken again at each point, and the connections must be re-made before another signal can be sent. In Fletcher's apparatus we have a battery with one terminal to earth, a line with one end to earth containing at various points the necessary apparatus and a recording apparatus. The methods adopted for carrying out the arrangement are shown in the accompanying illustrations. At each station to be visited by the watchman the apparatus represented in Fig. 1 is erected, except the final station, where the apparatus shown in Fig. 2 is placed. The mechanism is contained in neat walnut boxes, about 8in. by 6in. At the intermediate stations the ends of the line wire are connected to two terminals. One of these terminals is connected to the armature shown in an angular position above the horseshoe magnet. The other is connected to a contact spring behind the white disc, so that in the position shown the circuit is broken, and no current can pass the apparatus. To complete the circuit the watchman inserts a key through the door, and turning a lever contained in the box above the armature, he depresses the armature into contact with the pole

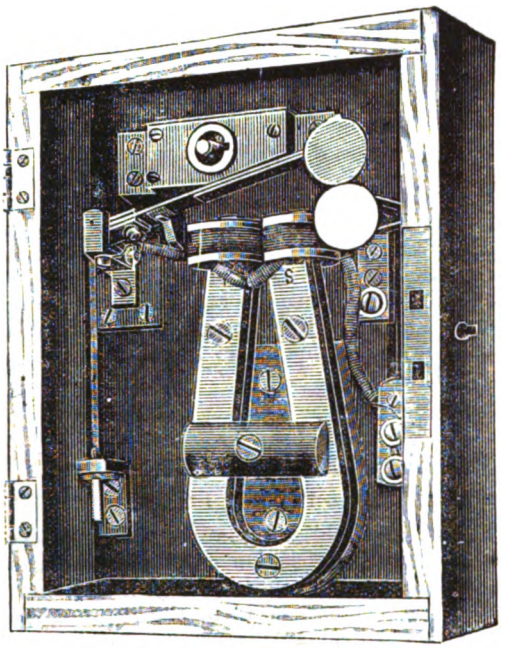

Fig. 1.—Apparatus for Intermediate Stations.

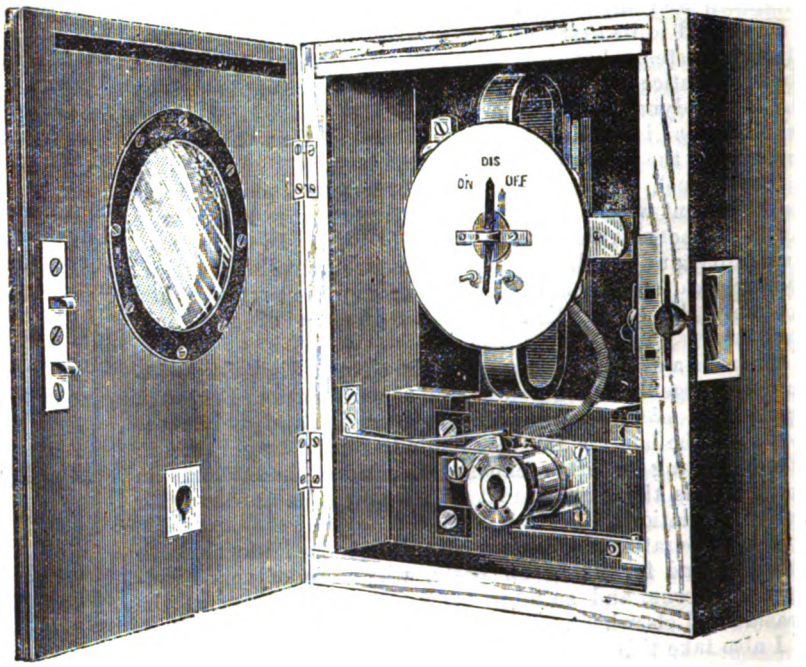

Fig 2.—Apparatus for Terminal Stations.

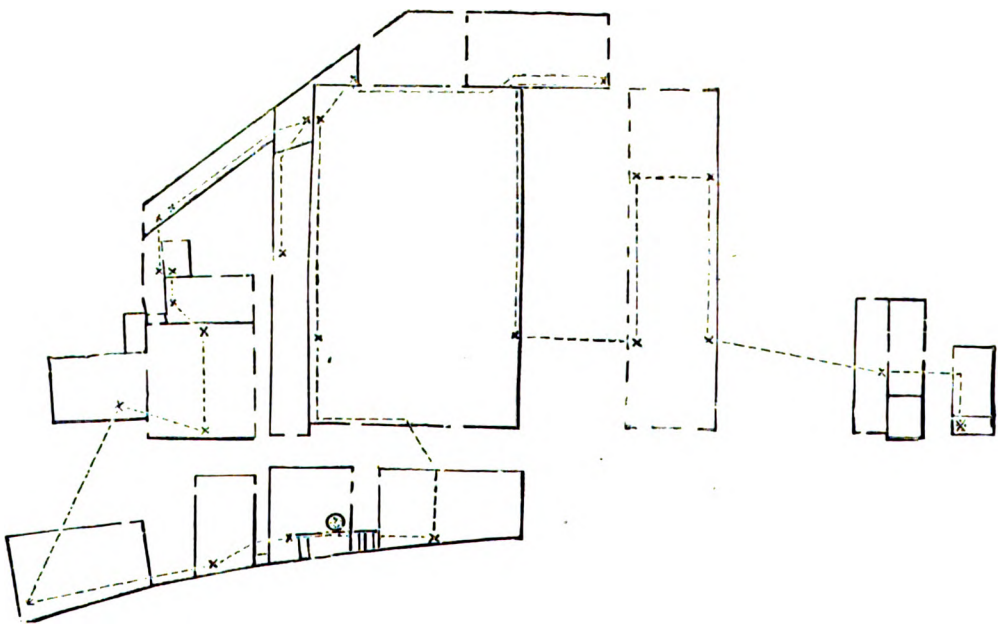

Fig 3.—Plan of a "Detector" Installation.

Digitized by Google

pieces of the magnet, the attraction of which holds it in position. On the end of the armature is a red disc, which then covers the fixed white disc, and thus gives the watchman an indication that he has made the necessary connection. The disc is visible through a circular piece of glass in the door of the apparatus. Suppose the watchman to have made his round, and to be about to transmit the recording current. Upon the poles of the magnet there are mounted two soft iron pole pieces, surrounded by coils of wire now included in the circuit. These coils are so wound that on receiving a current there will be induced in the pole pieces a contrary magnetism to that of the horseshoe, and the attraction of the latter for the armature will therefore be greatly weakened, when the opposing spring pressing back the armature overcomes the magnet pull and pushes back the armature into the position shown, and thus breaks the circuit. The instrument in use at the terminal station is shown in Fig. 2. Here the watchman inserts his key as before, which then turns the commutator opposite the keyhole. By this action the circuit is completed, and at once a current of electricity flows along the line, and through each apparatus, with the result described. If every station has been visited, and the necessary contacts made, the needle on the dial will be deflected; but if one or more stations have been omitted the needle will not be deflected till the contacts have been made. The position of the needle shows the watchman if any contact has been omitted. If at "dis," something is wrong, and must be put right; but if the needle passes first to "on" and then to "off," all is right and ready for the next round. The record is permanently made by including, at any convenient place, an electro-magnet in the circuit. This magnet governs a pencil which traces a mark on paper or card driven by a clock, so that a mark will be produced on the diagram for every round completed. The positions of these marks will show exactly how often and at what periods the man has completed his rounds.

To prevent the armature being shaken down or falling, otherwise than by legitimate means, a locking arrangement is provided. The points at which contact is made are self-cleaning, so that the circuit may not be interrupted by dust. The front of the lock is covered by a plate of glass (*see* Fig. 2), between which and the lock is inserted a piece of paper printed with a special design. This paper can only be inserted or withdrawn when the box is opened, and the key cannot be inserted without making a hole through the paper, and thus rendering any attempt at tampering with the apparatus at once apparent. The simplicity of the system is very obvious. To prevent a too-cunning watchman from joining over the instruments with pieces of wire and then sending currents at his will, all the connections are made inside the boxes, and nothing but insulated wire is available outside, so that an attempt at a fraud of this character would be doubly indicated—first, by the nature of the deflection made by the pencil, and secondly, by the existence of bare wire at each side of the instruments. A typical method of the arrangement of the wire and stations is given in Fig. 3, which represents an actual installation. The dotted line represents one circuit or round and the broken line another, the various stations being shown by small crosses. The whole of the requirements seem to have been well considered, and we have no doubt the apparatus will be found of great service in factories, railway goods yards, and, in fact, wherever watchmen are employed.

---

Fire Risks and Electric Lighting.—The Government have entered into a contract for the lighting of Bethnal Green Museum by electric lamps. Mr. Musgrave Heaphy, C.E., of the Phœnix Fire Insurance Company, has been commissioned to inspect the installation, and report as to the fire risks, if any. We may remark that the whole work has been carried out under the rules drawn up by the Phœnix Office for electric light installations. These rules have proved so satisfactory as regards safety that no fire has yet occurred in places where they have been enforced.

## A HISTORY OF ELECTRIC TELEGRAPHY TO THE YEAR 1837.

BY J. J. FAHIE, MEMB. SOC. TEL. ENGS. AND ELECS.*

Note.—Being anxious to make his History as complete as possible, the Author will be grateful to his readers for any information, no matter how small, in relation to the subjects treated of in these pages.

(continued from page 203.)

### Chapter VI.—Electro-magnetism and Magneto-electricity.

#### History in Relation to Telegraphy.

Faraday next took a ring of soft iron, round the two halves of which he disposed two copper-wire coils. In passing a current through one coil, and thus magnetising the ring, a current was induced in the other coil, but, as in the former cases, only for an instant. When the primary current ceased, and the magnet was unmade, an opposite current shot through the secondary coil. The primary coil was now suppressed, and the piece of soft iron embraced by the secondary coil was magnetised by a couple of powerful bar magnets, with which contact was alternately made and broken. Upon making contact the needle of the galvanometer was deflected, continuing the contact the needle became indifferent and resumed its first position, and on breaking contact it was again deflected in the opposite direction, and then became once more indifferent. When the magnetic contacts were reversed the deflections of the needle were also reversed.

In order to prove that the induced current was not occasioned by any peculiar effect taking place during the formation of the magnet, Faraday made another experiment in which soft iron was rejected, and nothing but a permanent steel magnet employed. The ends of the empty helix being connected as before with the galvanometer, either pole of the magnet was thrust into the axis, when immediately the needle was momentarily deflected. On rapidly withdrawing the magnet a second and instantaneous deflection ensued, and in the opposite direction.

The strength of these induced currents depends on many circumstances; as on the length and diameter of the wires of the coils, the energy of the inducing current, or the strength of the magnet.

Hitherto, in order to produce the phenomenon of induction by electric currents we have spoken of two conductors—one for the inducing, and another for the induced current; but experiment has shown that the same results can be obtained with only one conductor, and in this case the phenomenon is termed the induction of a current upon itself. In the sparking of relays and commutators of dynamo machines, &c., we have familiar examples of this action. Its discovery we owe to Professor Henry, of America, as far back as 1832. He was the first to observe that when the poles of a small battery are united by a copper wire by means of two mercury cups a brilliant spark is obtained at the moment the circuit is broken by raising one of the ends of the wire out of its cup of mercury. To obtain this effect, however, the wire must not be less than twelve or fourteen yards long, and if, further, it be coiled into a helix the effect will be greatly increased (Silliman's *Journal*, Vol. XXII.).

Faraday made a particular study of this phenomenon, and showed the existence of the *extra current* not only on the breaking, but also on the making of the circuit. To the former he gave the name of *extra current direct*, to the latter *extra current inverse*. The latter, of course, cannot be perceived, since it flows in the same circuit as the current of the battery itself, and cannot be developed until this current is established, and consequently not until the circuit is closed. As it moves in a contrary direction, it has the effect of diminishing for an instant the strength of the battery current, and hence the retarding effects observed in magnetisations by means of the current.

---

### Chapter VII.

#### Telegraphs based on Electro-Magnetism and Magneto-Electricity.

"The invention all admired; and each how he
To be the inventor missed;—so easy seemed
Once found, which yet unfound most would have thought
Impossible."—Milton's "Paradise Lost," book vi.

#### 1820.—Ampère's Telegraph.

Very soon after Oersted's discovery of the deflecting power of the current, La Place, the distinguished French mathematician,

* The author reserves all rights of translation.

Digitized by Google

suggested its employment for telegraphic purposes; and, on the 2nd October in the same year (1820), Ampère, in a paper read before the Paris Academy of Sciences, sketched out roughly a telegraph in which the signals were to be indicated by the deflection of small magnets placed under the wires. His idea was a purely theoretical one, and was thrown out simply *par parenthèse* in the course of his memoir.

He says:—"According to the success of the experiment to which La Place drew my attention, one could, by means of as many pairs of conducting wires and magnetic needles as there are letters, and by placing each letter on a separate needle, establish, by the aid of a pile placed at a distance, and which could be made to communicate by its two extremities with those of each pair of conductors, a sort of telegraph, which would be capable of indicating all the details that one would wish to transmit through any number of obstacles to a distant observer. By connecting with the pile a key-board, whose keys would carry the same letters and establish the connection (with the various wires) by their depression, this means of correspondence could be established with great facility, and would only occupy the time necessary for touching at one end, and reading at the other, each letter."*

It will be seen from this passage, which we have literally translated from the original, that Ampère makes no mention of surrounding the needles with *coils of wire*, as is so frequently stated by writers on the telegraph. Indeed he could not then have even heard of the galvanometer; for, although Schweigger's paper on the subject was read at Halle on the 16th September, 1820, it was not published until the November following.

### 1830.—Ritchie's Telegraph.

In order to increase the effect of the current on the needles, and to enable this effect to be delivered through a great length of intervening wire, Professor Fechner, of Leipsic, suggested in 1829 enclosing the needles in the multiplier coils of Schweigger. He says in his *Lehrbuch des Galvanismus*:—"There is no doubt that if the insulated wires of twenty-four multipliers, corresponding to the several letters of the alphabet, and situated at Leipsic, were conducted underground to Dresden, and there connected to a battery, we could thus obtain a means, probably not very expensive comparatively speaking, of transmitting intelligence from the one place to the other, by means of signals properly arranged beforehand. I confess it is a very seductive idea, to imagine that by some future development of such a system, a communication between the central point and the distant parts of a country can be established, which shall consume no time, like communication between the central point of our organism and its members by means of the nerves, by what appears to be a very analogous arrangement"† (p. 269).

Acting on this suggestion, Professor Ritchie, of the Royal Institution, London, improved upon Ampère's plan; and, on the 12th of February, 1830, exhibited a model of a telegraph in which were twenty-six metallic circuits and twenty-six magnetic needles, each surrounded by a coil of wire.

The exhibit is thus referred to in the *Philosophical Magazine*, for 1830 (Vol. VII. p. 212):—"Feb. 12.—This evening Ritchie briefly developed the first principles of electro-magnetism, with a view of setting forth, in a distinct and practical manner, M. Ampère's proposal of carrying on telegraphic communication by means of this extraordinary power. Of course, the principle consists in laying down wires, which at their extremities shall have coats [coils] of wire and magnetic needles so arranged, that, when voltaic connections are made at one end of the system, magnetic needles shall move at the other. This was done by a small telegraph constructed for the purpose, where, however, the communication was made only through a small distance, the principle being all that could be shown in a lecture room."‡

In his paper "On a Torsion Galvanometer," Ritchie refers to the subject in these words:—"We need scarcely despair of seeing the electro-magnetic telegraph established for regular communication from one town to another, at a great distance. With a small battery, consisting of two plates of an inch square, we can deflect finely-suspended needles at the distance of several hundred feet, and consequently a battery of moderate power would act on needles at the distance of a mile, and a battery of *ten* times the power would deflect needles with the same force, at the distance of a *hundred* miles, and one of *twenty* times the force, at the distance of *four hundred* miles, provided the law we have established for distances of seventy or eighty feet hold equally with all distances whatever."§

In speaking thus guardedly, the learned professor had evidently in view Barlow's experiments of 1824, which seemed to prove the utter impracticability of all such projects. Barlow then wrote:—"In a very early stage of electro-magnetic experiments it has been suggested [by Ampère] that an instantaneous telegraph might be constructed by means of conducting wires and compasses. The details of this contrivance are so obvious, and the principles on which it is founded so well understood, that there was only one question which could render the result doubtful, and this was, is there any diminution of effect by lengthening the conducting wire? It had been said that the electric fluid from a common electrical battery had been transmitted through a wire four miles in length without any sensible diminution of effect, and to every appearance instantaneously, and if this should be found to be the case with the galvanic circuit, then no question could be entertained of the practicability and utility of the suggestion above adverted to.*

"I was, therefore, induced to make the trial, but I found such a sensible diminution with only 200 feet of wire as at once to convince me of the impracticability of the scheme."†

Dr. Jacob Green, of Jefferson College, Philadelphia, re-echoed this opinion in 1827; and there can be no doubt that the opinions of such men, so clearly enunciated, and supported by such apparently irrefutable experiments, had the effect of retarding for a while the introduction of electric telegraphs.

### 1825-37.—Schilling's Telegraph.

The invention that we are now about to describe is a very interesting one, not only because it was by far the most practicable of the proposals that had hitherto been made, but because it was the prototype of our well-known needle instruments, and was the immediate cause of the introduction of electric telegraphs into England.

According to Dr. Hamel,‡ Baron Pawel Lwowitch Schilling (of Carstadt), then an *attaché* of the Russian Embassy at Munich, saw for the first time, on the 13th August, 1810, a telegraph (Sömmerring's) in action, and so impressed was he with the beauty and utility of the contrivance that, from that day, electricity and its applications became one of his most favoured studies. In the following five, or six, years his duties frequently took him to Munich, and at these times he was a constant visitor at Sömmerring's house, whither he delighted to bring his friends from all parts of Europe to witness the performances of the telegraph. Indeed, during much of this time he may be said to have lived in an electrical atmosphere in the society of Sömmerring, Schweigger, and other kindred spirits.

Schilling's first application of electricity was to warlike ends. We learn from Hamel§ that the war impending between France and Russia, in 1812, made him anxious to devise a conducting wire which could be laid, not only through moist earth, but through long stretches of water; and which should serve for telegraphic correspondence between fortified places and the field, as well as for exploding powder mines.

So diligently did he work at this task that before the autumn of the same year he had "contrived a subaqueous galvanic conducting cord" (a copper wire insulated with a solution of india-rubber and varnish), and an arrangement of charcoal points, by means of which he was able to explode powder mines across the Neva, near St. Petersburg. At Paris, during the occupation of the allied troops, in 1814, he also frequently ignited gunpowder across the Seine with this *electric exploder*, to the great astonishment of the *gamins*.

In the next ten years (1815-25), Schilling divided the spare moments of a busy diplomatic and military career between lithography, an art then recently developed at Munich and

* *Annales de Chimie et de Physique*, Vol. XV., p. 73.

§ *Journal of the Royal Institution*, October 1830, pp. 37-8.

* It may save some future inquirer a good deal of trouble if we here refer to a supposed early suggestion of an electric telegraph, which we find thus recorded in *Notes and Queries*, for October 30, 1858, p. 359:—

"In *Notes to Assist the Memory*, 2nd edit., 1827 (the first edition of which was published in 1819), the following note is added to the article on telegraphs:—'The electric fluid *has been* conducted by a wire four miles in length, apparently instantaneously, and without any diminution of effect. If this should be found to be the case with the galvanic circuit, *an instantaneous telegraph* might be constructed by means of wires and compasses.'"

Now if this passage occurred in the 1819 edition it would be prior to Oersted's discovery! Our curiosity was aroused in the highest degree, and we instituted a fatiguing search for the book in the British Museum. We found at last a small 12mo volume, of which the following is the full title: *Notes to Assist the Memory in Various Sciences*, London, John Murray, 1825. On the face is written in pencil "By Walter Hamilton, M.R.A.S." The note above quoted appears on p. 110. This is the only book of the name in the British Museum, and there is no mention anywhere of a previous edition. The writer in *Notes and Queries* must therefore be wrong in his figures, and this will appear all the more certain on comparing the words of the note with those of Barlow, which we give in the text.

† *Edinburgh Phil. Journal*, for 1825, Vol. XII. p. 105.

Digitized by Google

which he was anxious to introduce into Russia, and electricity. In these circumstances, then, the surprise is, not that he brought out an electric telegraph of his own construction, but that he did not do so at an earlier date than the one usually assigned. Dr. Hamel vaguely fixes this date at about 1825, for he says that the Emperor Alexander (who died on 1st December, 1825) "had been pleased to notice the invention in its earlier stage."*

Schilling's apparatus was based on the property of a voltaic current to deflect a magnetic needle. It is sometimes described as a single needle telegraph, and sometimes as one with five or six needles. What seems probable is that he tried many arrangements, that he first constructed a telegraph with one needle, and was thence led on to combine several into one system, so as to be able to transmit a number of signals at once.

(TO BE CONTINUED.)

## EASTERN TELEGRAPH COMPANY (LIMITED)

The twenty-third half-yearly ordinary general meeting of the Eastern Telegraph Company was held on the 24th inst., at the City Terminus Hotel, under the presidency of John Pender, Esq., M.P.

The SECRETARY (Mr. George Draper) read the notice calling the meeting, and the minutes of the last meeting, which were read and confirmed by the present meeting.

The CHAIRMAN stated that the revenue for the six months ended September 30 last amounted to £283,070, or a decrease of £58,081 as compared with the corresponding period of 1882, mainly owing to the reaction consequent on the termination of hostilities in Egypt. At the corresponding period of 1882 they paid a dividend and bonus of 6 per cent. on their ordinary capital, and carried forward £56,836, and this time they paid the same dividend and bonus, and carried forward £13,679. They were also paying interest on additional capital. He was happy to say that their current revenue was satisfactory, and that at the end of the financial year they hoped—they saw their way to it, indeed—to pay the same dividend as they were paying that day. The chief decrease in the revenue was in traffic with Egypt, but there had been a serious falling off in the receipts from the Black Sea Company, which was worked by this Company, no remuneration being paid to the directors or the officials for this service. An interruption of seven weeks deprived the line of all revenue for that period, and the Eastern Company under its agreement had to pay the working expenses of the Black Sea Company, with the exception of Odessa, in consideration of receiving all earnings in excess of 4 per cent. on its nominal capital. The return from this investment, however, even last year was nearly 5 per cent, but in previous years they had over 7 per cent. The Eastern and South African Company's dividend was 8 per cent., the same as last year. The subsidies in connection with that company's system supplemented the traffic to a considerable extent. As they were now receiving 8 per cent., with improved trade they were not likely to do worse. Their ordinary working expenses had been £80,849, being an increase of £11,040 when compared with the corresponding period of 1882, but a decrease as compared with the March half of 1883 of £6,978. The general expenditure in London had been £1,573 more. At the stations the increase had been £5,627, principally in salaries (£2,723). He might mention that during the time of the cholera in Egypt they considered it of the highest importance to keep their staff as comfortable as possible. The expenses of the issue of the debenture stock had been £2,487. They would, however, better understand the general increase of expenditure when he mentioned that their mileage of line was now 18,225, as against 16,825 in September, 1882; the number of their stations 49 as against 46, and the number of their staff 500 against 464, excluding messengers, servants, &c. The expenses of repairs and renewals of cables had been in the past half year only £29,520, showing a reduction of £27,281 as compared with the same period of 1882. Two of their ships were at present in dock in London, and he might say that they could never be better employed, so far as the Company was concerned, than in doing nothing and lying in dock During September and October the managing director and he visited the stations. They opened a new station at Trieste, and another at Corfu. They afterwards went to Athens, and saw that a considerable improvement and extension might be made there. They themselves entered into negotiations with M. Tricoupis on behalf of the Greek Government, and he believed that the arrangements made would result in considerable benefit to the Company. They next proceeded to Constantinople, where they found that ample scope existed for business. The Turks had now in anticipation a very considerable extension of the cable system. Negotiations were pending, and he would now merely say that he believed they would result in considerable benefit to the Company. They had recently obtained considerable influence in connection with the Direct Spanish Company's system, and they had also made an agreement to purchase the undertaking of the Mediterranean Extension Telegraph Company. This agreement would require the confirmation of the Italian Government, which they had no doubt would be granted before long. They had also had some negotiations with the Egyptian Government regarding connecting their system with Suakim. The ship was now on the spot making the connection, and at their next meeting he hoped to be able to make a very satisfactory statement to them as to that transaction. As showing the position the Company now occupied, he alluded to the discussion which had taken place at late meetings in regard to the issue of the debentures of the Company. They had 6 per cent. debentures out, and it was considered a very bold step indeed to try to issue debenture stock at 4 per cent. He was, happy, however, to say that out of the £500,000 offered, £400,000 had already been allotted, and the other £100,000 was going off by degrees. He thought that that showed the confidence of the public in the soundness of the investment, and he had no hesitation in saying that, looking to the extended system the Company represented, it was now a real property. He concluded by moving the adoption of the report and accounts.

The VICE-CHAIRMAN (the Marquis of Tweeddale) seconded the motion, which was carried unanimously.

The retiring directors and auditors were re-appointed.

Mr. WILLIAMS observed that he noticed that only about half the reserve fund was invested, but he understood that the other portion consisted of money in cables, &c. He, however, thought that a higher rate might be obtained on their investments than the Company received.

The CHAIRMAN stated that they were not allowed to invest in any risky securities, and they could now scarcely buy North Western or any good railway debentures to yield more than 3½ per cent.

An extraordinary meeting was held afterwards, when the agreement with the liquidators of the Mediterranean Extension Company for the purchase by the Company of that company's cables and concessions was approved.

A vote of thanks to the chairman and directors brought the proceedings to a close.

* Hamel, Cooke's reprint, p. 41.

## THE WESTERN AND BRAZILIAN TELEGRAPH COMPANY (LIMITED.)

The eleventh ordinary general meeting of the shareholders of this Company was held at the City Terminus Hotel, on Wednesday, the 23rd inst., under the presidency of Sir Henry Drummond Wolff, G.C.M.G., K.C.B., M.P.

The SECRETARY (Mr. R. M. Cunningham) having read the notice calling the meeting and the minutes of the last meeting,

The CHAIRMAN said: Gentlemen, before moving that the report and balance-sheet be adopted, I would ask your leave to make a few remarks upon the present position of the Company. I think that if we look to the past history of the line our present position is at all events comparatively satisfactory. In the course of last year, in consequence of the competition that took place between us and the Brazilian land lines, we determined to lower our tariff rates to those of the land lines, and this we did by lowering our rates from 5f. 50c. per word to 1f. for half the line, and from 8f. to 2f. for the whole line. We did this about the beginning of the month of September, and for some time the experiment was very fortunate, but unhappily in the month of September the Brazilian Submarine cable was broken, and an interruption took place in the international traffic which was naturally most detrimental to us, but I am happy to say that since the resumption of working by the Brazilian submarine telegraph the returns that we have received from our traffic are most satisfactory. In fact, we have nearly, if not entirely, realised the same returns from our traffic that we did under the old tariff, and the local traffic is improving in a marked manner. In fact, I believe that we get of the international traffic a very large percentage—something like 88 per cent., and we hope (and there is no reason to make us believe to the contrary) that the reduced tariff will certainly turn out to our advantage, inasmuch as at the present moment, as I said before, the traffic is equal to what it was under the higher rates. The state of the cables is also satisfactory—at any rate comparatively so, and it contrasts favourably with that of the last six years, because this year we have had only 174 interruptions, as against 429 for the year before, which was about the average of previous years. The shareholders will also be glad to know that the policy adopted by the Company for many years of renewing cable out of the year's returns has been satisfactory, inasmuch as we have now absolutely renewed three-fifths of our cable, having changed the old deep-sea type of hemp cable for sheathed cable. Out of the 2,500 miles of our system 1,500 have been entirely renewed, and we do not suppose that there will be any cost for repairs on that section. With regard to the other thousand miles, we do not apprehend any necessity for renewing it for some time, as the type of old cable still in existence is adapted to the deep sea line, and whenever it has been inspected it has been found to be in a good condition. But supposing that we had to renew the whole of that thousand miles of cable, we have fortunately in our possession ample means to do so in the renewal fund. Indeed, if you look at the accounts you will find that we have a renewal fund of £146,000, which we consider a very adequate amount at the present moment, though, of course, we shall have to add to it hereafter. That £146,000, representing more than £2 a share, is certainly ample for renewing those thousand miles of cable if necessary. The attention of the Board has been turned also to the question of expenses, which perhaps are higher than we would wish them to be, but the principal expense is owing to the maintenance of the "Norseman." Now, considering the very large amount of repairs that has been necessary for so many years, the employment of the "Norseman" was absolutely essential. She is perhaps a larger vessel than is now required, because the experience which we have had from the working of the "Viking" shows that a smaller vessel would do equally well for the work. But our attention is being now devoted to the question of reducing those expenses, and negotiations have been undertaken with the view of diminishing them. I shall not refer further to this subject, as I conceive it would not be desirable to enter into any question of our negotiations with other parties, but the shareholders may rely upon it that we will do our best to diminish the expenses generally, and especially those connected with the "Norseman." I may say that the line we have to repair is, I believe, from the experience of others, the most expensive that exists in the telegraphic world, being on the coast; therefore, so far, the labours of the "Norseman" have been indispensable. With regard to other expenses, it must be recollected that a great deal of the confidence reposed in us in Brazil, which enables us to take up so much of the traffic, arises from the circumstance that the greater number of our *employés* are Englishmen, and have the confidence of the natives. There is more punctuality, and I think there is, perhaps, more secrecy in our line than it would be possible to have if we had *employés* who were not men of a very confidential character; but, naturally, if you send out Englishmen to a tropical climate you cannot expect them to expatriate themselves and undergo the discomforts consequent on their situation

Digitized by Google

except at considerable expense. The question of dividend will shortly be brought before you, and we think that that dividend may safely be paid, inasmuch as the money is in hand. We have, as I said, all this reserve fund entirely liquid, and the prospects that we have at the present moment of the traffic are exceptionally fair. I may say that this renewal fund is perfectly liquid. If you will go through the various items of the balance-sheet you will see how easily it can be obtained if necessary. During the first three months of the new year, as I have told you, owing to an unfortunate breakage of the cable between St. Vincent and Pernambuco, the returns will be small, but we hope to make that loss up to a certain extent by our traffic and also by certain recoveries which we have made, and which we hope to increase, through the recovery of the Central American cable. The last time we met we proposed to the shareholders the elimination from the accounts of certain items which had been objected to by the auditors, and those items in this balance-sheet disappear entirely. You are aware that we have reduced the nominal value of our shares, and I think that we have now a very clear and straightforward balance-sheet. Some time ago I informed the Company that negotiations had been undertaken with the Government of Brazil. They have not as yet made much progress; but I am happy to say that the British Government, through Lord Granville, has been good enough to instruct Her Majesty's Minister at Rio to interpose in our favour with the Brazilian Government, and at the present moment communications are going on. I think these are the principal points to which I wish to call your attention. I shall be very happy to answer any questions that any shareholder may put to me, but for the moment I shall content myself with moving "That the report and balance-sheet be adopted."

Mr. H. WEAVER seconded the motion.

Major WOOD, in answer to questions put by Mr. Morrison as to the relative expenditure of the Brazilian Submarine Company and the Western and Brazilian, said that shareholders might not be aware that in the expenses to which that gentleman referred they had a debenture interest on their line, which absorbed £27,600 a year, and whereas the Brazilian Submarine Company had only three stations to maintain, which were comparatively inexpensive, their Company had eleven, all of them being in the tropics, and they were exceedingly expensive to keep up. This Company had twenty-two shore ends as against six of the Brazilian Submarine. They also had two ships, whereas the Brazilian Submarine unfortunately had none. Their cable lay along the coast, and was consequently more subject to breakages than those in the deep sea. When the directors notified to the shareholders that they were compelled to employ two ships instead of one, the "Viking" was sent out, and she had more than justified the policy of the directors. The chairman had touched on the question of the "Norseman," but he quite agreed with Mr. Morrison as to the large expenditure in connection with that vessel. He believed that they would be able to carry out what the chairman had foreshadowed, and have a smaller ship, which meant less expense. With reference to the London expenses, he would like to say that it was found a good plan to do a considerable amount of checking work in the London office, instead of having it done at greater cost in the Brazils, a process by which they actually saved money, so that they had considerably more work to do at home than their friend and ally the Brazilian Submarine, a fact which must not be lost sight of in contrasting their relative expenses. As to otherwise employing their vessels when not actually engaged in cable work, experience in the past had shown them that it was impracticable to do so.

Mr. R. KENDAL thought the shareholders might safely leave the matter of expenditure to the Board. The comparison between the two companies was a most unhappy one, because it so happened that the Brazilian Submarine Company had little or no repairing to do. He thought there was room for some reduction in the expenses connected with the "Norseman," but presumed that that matter was under the careful consideration of the Board.

The CHAIRMAN in answer to a shareholder repeated that it would be impolitic at the present time to reveal the nature of the negotiations now pending between the Brazilian Government and the Company. The motion for the adoption of the report and accounts was then put to the meeting and declared carried unanimously.

The CHAIRMAN then proposed, and Mr. W. S. ANDREWS seconded, the payment of a further dividend (free of income-tax) at the rate of 2½ per cent. for the half year ending 30th September, which was agreed to.

Major WOOD proposed the re-election of Sir Henry Drummond Wolff, M.P., as a director of the Company, observing that the chairman's assiduous attention to the affairs of the Company, as well as his great experience and influence, had contributed in a great measure to the success which had attended the operations of the Company.

Mr. W. C. EARLE seconded the motion, which was carried unanimously.

The CHAIRMAN having briefly acknowledged this renewed mark of confidence,

On the motion of Mr. WEAVER, seconded by Mr. ANDREWS, Mr. D. H. Goodsall was also unanimously re-elected to his seat at the Board.

The Company's auditor (Mr. J. Weise) was likewise unanimously re-appointed.

Major COTTON proposed, and Mr. MORRISON seconded, a vote of thanks to the chairman and directors, which was passed, and the proceedings terminated.

## UNITED TELEPHONE COMPANY (LIMITED).

An extraordinary general meeting of this Company was held at the Cannon-street Hotel on the 22nd inst., for the purpose of considering and of passing (if approved) the following resolution:—"That the Bill which is proposed to be introduced into Parliament in the ensuing Session, intituled 'A Bill to afford to the United Telephone Company (Limited) Additional Facilities for Telephonic Communication in the Metropolis, and for other purposes,' is approved, subject to such additions, alterations, and variations, as Parliament may think fit to make therein." Mr. James Brand, the chairman of the Company, presided.

The SECRETARY (Mr. Thomas Blaikie) having read the notice convening the meeting,

The CHAIRMAN, in the course of his remarks in moving the resolution, said: The meeting is purely formal, to comply with the Standing Orders of Parliament, and to take the authority of the shareholders to go to Parliament for this Bill for proper authority, if we can get it, for laying telephone wires, whereby the business of the Company is conducted. As we proceeded with our work we found the difficulty of carrying on the business with these overhead wires growing, I may say, constantly; and we felt that the best way would be to face the matter at once, and go to Parliament for a Bill which will put the laying of the wires under some properly constituted authority. We do not want, of course, to ride roughshod over any one's property or rights, or even their susceptibilities, but of course we want some due regulations made. The want we supply by way of our telephone has now become a necessity all over the world, and we want to get proper authority to enable us to lay our wires with a minimum of danger to the public—if any exists at all—and also to meet the cry that is raised in some parts about the disfigurement of the streets caused by our cross spans and long spans, and so forth. There are plenty of schemes already created by people accustomed to this business, by which, if we had the requisite authority to cross the houses and streets in a proper way, our wires would by no means disfigure the streets. As regards the danger to the public, if any exists, we do not think very much about it. We believe it has been greatly exaggerated, and some writers in the Press seem to take it for granted that these wires are a matter of danger, and talk about a man not being able to walk about the streets without the chance of having his throat cut or sustaining some other serious injury. We ourselves, during the time we have been in existence—for the last four or five years—have not paid £50 for any damage at all caused by our accidents. We have the authority of Mr. Preece, a very eminent man in the electrical world, and electrician to the Post Office, who stated the other day at the Engineers' Society that out of 400,000 accidents that had occurred in the streets of London during the last sixteen years only two were in any way attributable to overhead wires. So far as that goes, I think it does away with the idea of danger. Of course one reason of our going to Parliament for a Bill is because it is said that we can lay our wires underground, and carry on our business just as effectually without any of the trouble and annoyance which they say exist from overhead wires. We know very well that communication can take place, and take place very satisfactorily, under certain circumstances, by underground wires, but it is not established at all satisfactorily that underground communication is as good as overground for telephone purposes. Besides that, we have not the power to go underground, and the expense would be something enormous. If we had the power, the streets, as a matter of fact, are already occupied. All the main thoroughfares of this city, and even the secondary thoroughfares, are now occupied by gas and water pipes, pneumatic tubes, telegraph wires, sewers, &c., and the Post Office have told us that if we applied to the authorities there they could not give us any of the leading thoroughfares. Again, imagine another Company being able to break up the streets in London. It is very difficult to get along now with one obstruction and another, and it would be worse with this fresh power. As I have said, too, the expense would be enormous, practically deterrent, and it would do away with all chances of a penny telephone, which has been so touchingly alluded to by Mr. Batten (one of the directors). The owners of property have been very kind and useful to us in many ways, and from a great many of them we have received a good deal of assistance. Others, however, have not treated us in the same way. Some people do not like the wires; but there is one thing that all owners of property should reflect on, especially in outlying districts and in back streets—that the telephone is a great benefit to the value of their property. People can have offices now if they choose in cheap places, some distance away from the centres of business, and be able to carry on their business as well as if they were close to the Royal Exchange, and so save a considerable amount. I do not know if you saw *The Times* of Saturday last, but if not I should like to read you an extract from Sir Arthur Hobhouse's letter, which really puts our view of the case a great deal better than I can. Sir Arthur Hobhouse says:—"It appears to our vestry (St. George's, Hanover-square) reasonably clear that whatever our dominion in the streets, we have not been made rulers of the air, and cannot treat wires placed there as trespassers upon us." Then he adds his own personal view and says:—"If other vestries take another view of their duty (as I understand our neighbours in Marylebone to do), it is possible that after three or four years of litigation a final decision on the point may be obtained from the House of Lords. Possible I say, but not certain, for long contested lawsuits are sometimes decided on by-issues. Let us, however, suppose that the question is decided, and decided in favour of the vestries. What then will be the state of things? Why, that in each of the thirty-nine London districts an independent authority will have an absolute discretion to say whether wires shall hang suspended over the streets or not. Chelsea may decide to allow them freely, St. George's under conditions, Paddington to allow a few, Marylebone to forbid them altogether, and so on through London. Is that a workable, or even a tolerable jurisdiction to apply to operations which must extend through a number of districts? It will be found that the same organic defects which have prevented Londoners from making their own arrangements with respect to water, light, tramways, markets, public conveyances, and other affairs common to more than one parish will operate to make parochial control over wires either ineffective or intolerably capricious and vexatious. In what way the control should be exercised I do not attempt to forecast. I feel with Sir C. Dilke that there are difficulties here, as there are in most matters concerning a large number of interests. I only urge that in a matter concerning the public some public authority should have an effective voice. If there were a Government of London there would be no difficulty in saying where the authority should be found." That is a matter of opinion of course, but I quite agree that there should be some public authority; and I am glad to say that we have anticipated the opinion which has been expressed by so great an authority as Sir Arthur Hobhouse, and gone to the House of Commons to get this Bill to do that which he says is an absolute necessity. I now have to ask you to give us your authority for what we propose to do, and I move this resolution (as above).

Mr. JAMES STAATS FORBES: I have great pleasure in seconding the motion, and do not know after what our able chairman has said that I can add much. I have some experience of parliamentary com-

Digitized by Google

mittees, and whatever may be said of private legislation I have discovered this: that it is a very good place to test ignorance or misconception; and I think when this Bill is before a parliamentary committee, with the aid of counsel and science, we shall be in position to dissipate all the fears which seem to be entertained of these overhead wires. Of course all things in great cities are questions of compromise. I suppose that we at all events are perfectly satisfied among ourselves of the enormous value of this telephonic system from a commercial as well as a social point of view. If that be so, the interest of the community would appear to lie rather in giving facilities than in presenting every kind of obstruction; and although we felt it would be wise to go on discreetly, as we have done, we have arrived at the conclusion, which every day is confirmed by our experience, that this thing is too important to the public to remain dependent on what you may call the goodwill of individuals, or even of local authorities. We therefore thought the time had arrived, looking at the importance of this communication and its rapid extension, to test before Parliament the value of all that could be said against it. The danger appears to be *nil*. We have heard from the chairman, who also had it from a very eminent authority, Mr. Preece, that practically there is an entire absence of danger. Of course the thing must be subject to some reasonable control, and that is what the Bill provides for. One knows too well—we old dwellers about Loudon—what the pitfalls are that await us in every direction. Omnibuses are very useful, so are cabs and steamboats, and I myself believe that railways are rather useful; but we know the large tribute that is every year paid in London to the necessities of these things in the deaths and accidents which arise from their use in the public streets and other places. In fact, you cannot have any great public advantage without some drawbacks: but in all my experience—and I have had a great deal in this sort of thing—there is nothing I know of where the relative advantage to the public is purchased at so small, absolutely small, a risk of either danger or inconvenience as this great telephonic system. Then, the unlearned say, why do you not carry the wires under the streets? Well, the chairman has given you one reason, and I may give you another. This telephonic business is very peculiar. The thing itself is so exceedingly sensitive that in the air seems to be, at present at all events, the only effective way of working it. Some one has said—I am not a scientist, and therefore do not know whether the statement is correct—that if you put a telephone wire under the earth you diminish its value by 15 times out of 16. That simply means that you so destroy the efficiency of this very delicate instrument that you make it comparatively useless. We know that a small change in the atmosphere, the neighbourhood of some building, or telegraph wire, will interfere with it. If the public are to have this thing it must be on conditions on which it is possible to have it, and one of the conditions seems to be overhead wires. I daresay we shall teach the unlearned a good deal through the evidence of our scientific witnesses when we come before Parliament, and I believe that Parliament will be found in this, as in a great many other things, to listen to reason, and measure the public advantage against the public inconvenience—as they do in railways, docks, and other things.

The SOLICITOR (Mr. Winterbotham) then pointed out the general purport and effect of the Bill, reading the heads and some of the principal clauses. Clause 6 stated that, "Subject to the provisions of this Act the Company may execute works as follows (that is to say):—(1) They may place and maintain a telephone wire under any street and may alter or remove the same. (2) They may place and maintain a telephone wire over, along, or across any street and place, and maintain posts in or upon any street, and may alter or remove the same. (3) They may, for the purposes aforesaid, open and break up any street and alter the position thereunder of any pipe (not being a main) for the supply of water or gas. (4) They may place and maintain a telephone wire and posts under, in, or upon, over, along, or across any land or building, or any railway or canal, and may alter or remove the same." Clauses 7 and 8 contained provisions as to compensation and gas and water pipes; Clauses 9 and 10 provided that the Company should not place telephone wires under any street without the consent of the local authorities, or break up the streets without first giving them notice; Clauses 17, 18, 19, and 20 contained regulations as to the suspension of wires, &c., along, over and across streets; restrictions as to breaking up private streets; provisions as to the height of wires over houses; and regulations as placing posts near dwelling houses. Clause 21 contained provisions under which, for building or other purposes, any owner, occupier, &c., of land or buildings might require the removal of works of the Company. Clause 24 was, he said, an important clause, dealing with the inspection of the wires by the Board of Trade. It was as follows:—"In every case where by virtue of any enactment herein contained, the Company shall have suspended or carried a telephone wire over, along, or across any street or land or building or railway or canal, the Board of Trade shall, upon credible information being given them that any such telephone wire is or is likely to become dangerous to the public safety, make an inquiry into and inspect the condition of the telephone wire complained of, and make such order with respect thereto and upon such terms as may seem to be necessary and expedient in the public interest under the circumstances of the case, and the Board of Trade also of their own motion and without receiving any such information may from time to time after twenty-four hours' notice to the Company proceed to inspect, test, examine, and inquire into the state of repair and condition of any telephone wires or posts to which such notice shall refer, and may make such order as to the removal, repair, or alteration of any such telephone wires or posts as shall seem to the Board of Trade necessary for the protection of the public." The next clause provided that the Board of Trade might make and enforce rules for preventing danger from the Company's works; and the remaining clauses provided that the Company was to be responsible for all damages; as to protecting their wires from distress; penalty for injuring their works; reserving their powers under the Limited Liability Acts; as to works affecting Crown property; and for saving the rights of the Postmaster-General.

The CHAIRMAN then put the resolution, which was carried unanimously.

On the motion of Mr. ROBINSON KENDAL, seconded by Mr. E. H. GALSWORTHY, a vote of thanks was passed to the chairman and directors.

The CHAIRMAN, in reply, stated that the directors were most ably seconded by Mr. Morgan, the managing director, to whom a great deal of the success and progress of the Company was due.

The proceedings then terminated.

## ELECTRIC SUN LAMP AND POWER COMPANY (LIMITED).

The annual general meeting of the shareholders of this Company was held at the City Terminus Hotel, Cannon-street, on Tuesday, the 22nd inst., the Right Hon. Lord Brabourne in the chair.

The SECRETARY (Mr. J. Reeve) having read the notice convening the meeting,

The CHAIRMAN, in moving the adoption of the report and accounts, said that the shareholders would naturally expect from him an explanation of the circular which they had just heard, and some account of the general position of the Company, and of the reasons of the directors for proposing the adoption of that circular. It was just eight months since they held their last meeting, and he then addressed the shareholders full of the belief that they were about to attain a success which would have been, as he hoped, unparalleled (although he did not say so) in the annals of electric lighting. He told them then that they had three strings to their bow. They had the South Kensington Museum, which they were lighting; they had various country installations, and they had the hope of lighting from house to house in London, under the vestries of St. James's and Marylebone, having the belief that they would obtain a license to do so, which, if they had obtained it, would have enabled them to work, as they hoped, so as to announce by this time remunerative returns. He told them at the time that the battle of the great or non success of this Company was to be fought out in London, and he had great confidence that the battle would be speedily and successfully decided. It was after that meeting (and he wished to be particular on this point, because some of the shareholders had addressed letters to him under the impression that the Board must have known everything before the meeting which had come to their knowledge up to the present time)—it was after that meeting that they became aware of certain difficulties which they did not know of before. There was no concealment necessary in the matter. The Act of Parliament which was passed in 1882, just after the formation of the Company, had to be interpreted and regulated by the Board of Trade, and the Board of Trade's regulations were not made known to them until that meeting had been held, and they had no reason to suppose that these regulations would have been otherwise than conducive to the development and prosperity of their lamp. What they found, however, in a short period was briefly this. In the first place he would remind them that there were two conditions under which a company could work, either by obtaining a provisional order for 21 years, or agreeing with the local authorities for a license which was to last for seven years; and they found, when they came to inquire practically into the matter, that the same conditions were to be required from them for a period of seven years which were to be exacted if they had had a provisional order for 21 years. Now they had passed the time for getting the 21 years' order. A provisional order could only have been obtained at considerable expense, and their Company was not formed soon enough in point of fact to get the opportunity of obtaining that privilege. Therefore it was evident that if they were expected to do as much for the benefit that was to accrue in seven years as they were expected to do in 21 years they were handicapped to a considerable extent. They would have been obliged to lay down mains in the streets, and thus incur an expense which they could not hope to be remunerated for if they had only seven years to run. There was another thing of a more serious character. The Board of Trade declared that the parallel system was the only one on which lighting from house to house could be permitted. The result was that while it was certain that the series system might work very well, and that the "Sun" lamp was the best that existed, there were, to say the least of it, great doubts as to its working on the parallel system. Opinion had been divided on the matter, and although there was nothing about the parallel or series system in the Act of Parliament, the moment the Board of Trade said that no other system would be permitted, that of course entirely altered the whole position of affairs. His brother directors and himself felt at once, therefore, that they would not like to be responsible for going on with the project of lighting from house to house, especially as its full development would require, as he had said at the last meeting, the subscription of a greater capital—that they could not be responsible for that until it was properly shown, and thoroughly ascertained, that the lamp could be worked on the parallel system. From their experience at South Kensington and elsewhere, in factories, and certain classes of buildings where isolated and particular attention could be shown to the lamp, there was no lamp comparable to the "Sun," and for certain places and under certain conditions, they believed still that it was the best that had appeared, but he for one could not be a party to proceed upon lines which they were not sure could be successfully carried out, and they doubted whether it would not be their duty to advise the Company either voluntarily to wind up, or to suspend its operations, or else adopt the other alternative to reduce the Company to very humble limits, and to confine itself entirely to attempting to make the light work in those isolated buildings and factories of which he had spoken, and without any hope of immediate dividends, reducing expenditure and waiting, as it were, until electricity became more developed and the merits of their lamp became known, when they might see a good future before them. But while they were doubting, they had to consider the circumstances under which a voluntary liquidation could take place. One circumstance was of a very important character. At the commencement of this undertaking the directors, being very anxious that they should not cripple the Company by taking away all its ready cash in payment of the vendors, reduced that payment to the smallest possible amount by giving them shares. And the vendors met them very liberally in that respect. There was nothing to complain of on their part. But then arose the question that the vendors and those who had taken shares from the vendors had a very considerable voting power in the Company, and that unless they desired that there should be a voluntary liquidation, or some other arrangement to which they could be parties, it was impossible to carry out any such arrangement. He was bound to say that the vendors held to the opinion that the lamp was a good lamp, and that its development in the future was certain, and that nothing could be so injurious to the shareholders as to go into liquidation. That being their view, the directors thought it was absolutely their duty to support that which appeared to be the opinion not only of the vendors but those who, independently of the vendors, had taken the largest number of shares in the undertaking. Then it was evident that it was necessary to have as

Digitized by Google

great a reduction of expenditure as possible, and, instead of having a staff of directors and a large staff of other men under them, it was desirable to have a small number of directors, practical electricians, who would be able to give attention to the affairs of the Company, and who would reduce the expenditure, and thus bring about possibly a good future to the Company, and give the shareholders a return for their outlay. There was another consideration which weighed with them, and which he hardly liked to mention, namely, that if there had been a voluntary liquidation there would have been hardly anything left to divide among the shareholders, for the reason that the law said that those who ranked as fully paid-up shareholders were put on an equal footing with other shareholders, and the result of that would have been that the assets would have been almost all absorbed in paying the vendors, so that the vendors really in taking the course they wished to take were showing not only great confidence in the future of the undertaking, but great generosity, because instead of taking all that they could get they were desirous that the money which they might legally claim should with that which the shareholders paid be thrown into one common boat, and that they should mutually endeavour to make this Company ultimately a successful undertaking. They had felt it their duty to elect Mr. Brickdale (who held 1,000 shares in the Company) to a seat at the Board as a representative of the shareholders, and at the same time to yield their seats in favour of the gentlemen whose names appeared on the circular. He had himself such confidence in the lamp that he took 100 shares, and he was very anxious that there should be such a result as to give him a dividend on them some day. He was in the same boat with the shareholders, save that he and his brother directors had received certain reduced fees, the amount of which for his part he would have gladly sacrificed, if by so doing he could have prevented any gentleman from losing any money in the concern. But he did not think it was at all certain that they would eventually lose their investment, though up to this time they had not done that which they might have been able to do if they had not been subjected to such restrictions from the Government department as they could not have foreseen. Let them not think he was blaming the Government. They might have excellent reasons for those restrictions, such as the safety of the public, or their own investigations might have convinced them that only one form of developing electric lighting was proper and advisable in the public interest. But the fact had been to throw considerable doubt on the possibility of their working their lamp in the manner in which the directors believed it would have been most remunerative. It was possible those difficulties might be overcome. The men who were able to take the place of the present directors, if it was the will of the shareholders, were energetic and talented men who understood electricity, and if that was the case, they would know what rocks to avoid and what shoals to steer clear of, and the best way of developing the light. He was very far from giving up hope in the future of this lamp. Every one said there was no lamp like it, and he could not help thinking still, although there were difficulties to be got over, that means would be devised to surmount them, and that the "Sun" lamp would yet become what he thought at its inception it would have been [applause]. Of this he was sure, that if it was to succeed it must be by a vigilant attempt at economy, and by endeavouring to light in the direction in which it had been found to answer, since they could not light from house to house. He did not see why if the lamp was a success at South Kensington (where it had been an approved success) it should not be largely used for factories and such places, and he could not see why with care and attention it could not be developed and made in that way a remunerative business. Under the circumstances which he stated he did not think they could do better than place the management in the hands of those gentlemen who were the largest shareholders in the undertaking. Unitedly they held more than half the shares, and thus showed their confidence in undertaking the work, and that they would bring it to a successful issue. For his own part he was most ready to yield his position to them. At the same time he would give the new Board if elected all the support he could in carrying the concern to a satisfactory issue, and he thought the present directors had taken the wisest course in the interests of the shareholders in retiring in favour of those gentlemen.

Mr. JONES seconded the motion, remarking that it would be for the interests of the shareholders to adopt the policy suggested by the chairman. He expressed his approval of the "Sun" lamp, which he had been invited to see at the South Kensington Museum the previous evening. He had been told at the office that the light which he saw there could be supplied at the same price as gas, leaving for the shareholders a fair margin of profit, and there could be no doubt that if that was the case it would come to be very largely adopted.

Mr. LAVENFELDT, while concurring in the opinion that the "Sun" lamp was irreproachable from a lighting point of view, could not entertain sanguine expectations as to the future of the Company. It would be from five to ten years before the country was prepared to adopt electric lighting on a scale that would remunerate electric companies, and he therefore suggested that the Company should be wound up voluntarily. If this course were adopted the whole of the assets would be divided, giving them about 10s. a share, whereas if they prosecuted the business there was not the ghost of a chance of its succeeding, their assets would dwindle down to nothing, and, at last, they would be compelled to go into liquidation and lose everything.

Mr. M. GRANT thought that the previous speaker had shown in an otherwise able speech that he had an interest in the Company's going into liquidation. He could not concur in that gentleman's opinion. He then gave an outline of the history of the Company, referred to an interview which he had had with some of the head officials of the Board of Trade, who he said assured him that they would give the Company every possible assistance under the special powers which they possessed under the Act, so that he hoped they might yet conquer any difficulties that had arisen in that quarter. Every light had got its own special work to do. The special work theirs had to do had been explained by the chairman. It was admirably suited for factories, theatres, churches, restaurants, clubs, picture galleries, museums, large shops, railway stations, newspaper and printing establishments. Whenever large rooms were to be lighted, it was, *par excellence*, the light of the future. The present Board were entitled to the thanks of the shareholders for what they had done on the terms they had received [hear, hear]. The new Board, however, were willing to work more for the sake of improving the value of the shares they held, and their remuneration would only be £100 each, and with regard to the other officers of the Company, a similar system of economy was to be exercised. The principle now to be adopted was that each man would receive a minimum salary and a commission on the work done, an arrangement well received by every one connected with the Company. Therefore, from the directors downwards, it would be the interest of all connected with the business of the Company to exert themselves to make it prosper in the future.

A long discussion then ensued, in which several shareholders took part, as to the advisability of going into liquidation, or letting the Company go on under the proposed new *régime*, the majority of the speakers inclining towards the latter course.

The CHAIRMAN, in reply to questions, said that when the terms of the vendors were altered with regard to the purchase, a circular was sent to every person to whom an allotment of shares had been made, and every shareholder had then an opportunity of withdrawing if he pleased after knowing the number of shares that had been allotted. Besides, the whole subject was fully discussed at the statutory meeting, when Sir James Carmichael was in the chair. One could hardly blame the directors for believing that the money they originally raised was amply sufficient for the purposes of the Company. Electricity was yet in its infancy, as had been truly said by one speaker, and there might yet be a good future for the Company. He believed that by electing the gentlemen who were proposed as substitutes for the present Board, they would elect gentlemen who would not be able to evince a more sincere desire to promote the prosperity of the Company than the retiring directors, but who would by their practical knowledge give more attention to the technical details of the undertaking than he and his colleagues could do. If the Company were put into liquidation, the liquidator would call up the uncalled capital, and there would not be anything like the amount to be divided among the shareholders that one gentleman seemed to think. The retiring directors believed that their successors would eventually make the Company a success. He did not like to prophesy, for if he thought it was certain to be successful he would advise the present Board to continue in office, but he believed that the most likely way of adding to the assurance of that success was for the present directors to resign the management to the new Board, in whom they had the greatest confidence [applause]. The report and accounts were then adopted, there being but two or three dissentients.

Messrs. Price, Waterhouse, and Co., were unanimously reappointed auditors of the Company, at an annual fee of forty guineas, and

On the motion of Mr. M. GRANT, seconded and supported by several shareholders, the following gentlemen were elected as a new directorate in place of those retiring:—Mr. W. Perkins, Mr. Henry de Grelle, and Mr. Paul Cremieu-Javal.

A vote of thanks having been accorded to Lord Brabourne for presiding, the proceedings terminated.

## NOTES.

CABLE INTERRUPTED.—The cable between Pernambuco and Fortaleza is interrupted.

ORIENTAL TELEPHONE COMPANY.—We learn that this company have opened an exchange in Port Louis, Mauritius.

JAPAN.—A telegraph station has been opened at Fusan by the Japanese Government. The tariff will be 1·10 francs from Nagasaki.

THE SANITAS COMPANY.—This company have declared a dividend of 7½ per cent., making a total dividend of 10 per cent. for the year.

LONDON CENTRAL ELECTRIC RAILWAY.—The Bill asking for powers to construct this railway has passed the examiner and complied with standing orders.

SLIGHTLY BETTER.—During the week ending Saturday last five hours of sunshine were registered at Greenwich. This is a little better than none at all.

ST. GEORGE TELEPHONE COMPANY.—Mr. Justice Chitty has made an order for the winding up of this company, in pursuance of a petition by Messrs. Paterson and Cooper.

UNITED TELEPHONE COMPANY'S BILL.—This company's Bill, relating to wires, &c., having complied with the standing orders, and being unopposed, was passed by the examiner this week.

EASTERN EXTENSION TELEGRAPH COMPANY.—The coupons on this company's six per cent. debentures due yesterday (Friday) will be paid at the Consolidated Bank, 52, Threadneedle-street, E.C.

NEW BOOK.—We have received a copy of "Die Mortoren der Elektrischen Maschinen mit bezug auf Theorie, Construction und Betrieb." Von Th. Schwartze. It is published by A. Hartleben, of Vienna.

TELEGRAPHIC COMMUNICATION WITH HOLLAND.—An address to the Dutch Government is being circulated on the Bourse at Amsterdam which asks for better telegraphic communication with England.

HONOURS FOR AN ELECTRICIAN.—Sir William Thomson has been appointed a Foreign Knight of the Order "Pour le Mérite" by the German Emperor, at the instance of the Berlin Academy of Science.

SPANISH TELEGRAPHS.—Senor Couzada Villamil has just been asked to again undertake the general direction of the Spanish Posts and Telegraphs, an office which he occupied for several years prior to 1881.

INSTITUTION OF CIVIL ENGINEERS.—Last night (Friday) Mr. Edgar Smart was to read a paper before the first students' meeting of this institution for this session on "Some Elementary Electrical Notes."

ELECTRIC LIGHTING IN AUSTRALIA.—The *Argus*, of Melbourne, has made trial of the incandescent system for lighting its composing room. The current was supplied from the central station of the Australian Electric Light Company.

WESTERN AND BRAZILIAN TELEGRAPH COMPANY.—The traffic receipts of this company for the week ending Jan. 25, 1884, were £2,503, after deducting the "fifth" of the gross receipts payable to the London Platino-Brazilian Telegraph Company (Limited).

THE EDISON AND SWAN COMPANY.—We are requested to state that on and after February 1st, the only London office of the Edison and Swan United Electric Light Company (Limited), will be at 57, Holborn-viaduct, E.C. The Coleman-street office will be discontinued after that date.

SHOOTING PUNTS.—Messrs. Gilbert Bogle and Co., of Glasgow, are fitting Clark's motor and battery to shooting punts with success. A trial was made a few days since with a punt 23ft. long by 4ft. 6in. beam, and drawing 9in. aft. A speed of four knots an hour is said to have been attained.

THE SKRIVANOW BATTERY.—The battery alluded to in last week's "Notes" under this name, as being used to light the lamps on the ballet dancers' heads at the Paris Opera House, was supplied by Messrs. Elliott Brothers, of St. Martin's-lane, W.C. This firm are, we learn, the sole makers of this battery in England.

RATES TO CANTON.—The Great Northern Telegraph Company notify that the rate for messages from Hongkong to Canton will for the future be 5d. per word, with a minimum of seven words per message. The charge for messages from all stations in Great Britain to Canton will therefore now be 8s. 9d. per word.

THE CUBA SUBMARINE TELEGRAPH COMPANY.—At a meeting of the board of this company, held on Wednesday, it was resolved, after providing for the dividend on the preference shares, to recommend the payment of a dividend on the ordinary shares at the rate of 7 per cent. per annum, free of income-tax, leaving £594 to be carried forward.

ELECTRIC LIGHTING FOR THEATRES.—The special committee on theatres and public halls, appointed by the Citizens' Association of Chicago, recommended, in a recent report, the substitution of incandescent lamps for gas-burners in theatres. Circulars were sent to the proprietors of all the city theatres, requesting them to adopt the incandescent system of lighting.

THE EDISON LAMP.—A correspondent of the *Water-Gas Journal*, an American paper, has been making some photometric tests of Edison's incandescent electric lamps. He finds that the 16-candle lamps, when the glass is clean and bright, are of from 15·64 to 15·87 candle-power. When the glass is slightly covered with carbon the illuminating power falls to 12 or 13 candles.

SOCIETY OF TELEGRAPH ENGINEERS' LIBRARY.—Mr. A. J. Frost, librarian to the Society of Telegraph Engineers, has forwarded us a list of works that have been kindly presented to that library by Lady Siemens. The list includes the titles of several valuable books, and this latest addition to the society's already well-stocked library will doubtless be appreciated by the members.

TRAIN LIGHTING.—The Cheesewright primary battery has been tried on the South Eastern Railway during the week. A saloon carriage was fitted with three incandescent lamps, the current being supplied by cells placed in the guard's van. The light is said to have been very steady on the journey from Charing Cross to Dover. The company are, we believe, contemplating a more extended use of this means of lighting their carriages.

THE SUAKIM CABLE.—The Eastern Telegraph Company notifies the opening for traffic of Suakim, a new station in the Red Sea. Telegrams for Jeddah, which is connected by cable with Suakim, will also be accepted for transmission by this route. Before these lines are in our readers' hands, therefore, the Suakim cable will be completed. The cable would have been laid sooner, but that bad weather in the Red Sea prevented the Eastern Company's cable ship getting to work.

THE METROPOLITAN BRUSH COMPANY.—The directors of this company have issued a circular to the shareholders, calling their attention to the fact that the committee recently appointed to inquire into the affairs of the company have thought fit to go beyond the powers entrusted to them and to file a petition for the winding up of the company. The

Digitized by Google

directors think this course is a mistaken one and adverse to the shareholders' interests. We shall probably have something more to say on this subject later on, and we therefore refrain from expressing an opinion now.

THE METROPOLITAN FIRE BRIGADE.—In his report for the year 1883 Captain Shaw says:—"During the year there has been a large development of our telegraphic system, and we have now the following lines of communication in complete working order:—45 telegraphs between fire stations, 18 telephones between fire stations, 1 direct fire alarm between fire stations, 23 alarm circuits round fire stations with 151 call points, 4 telegraphs to police stations, 13 telephones to police stations, 16 telegraphs to public and other buildings, 13 telephones to public and other buildings, and 12 direct fire alarms to public and other buildings."

THE TONQUIN CABLE.—The Paris correspondent of the *Standard* telegraphs from that city on Wednesday night as follows:—"The laying of the anxiously-awaited Tonquin cable by the Eastern Extension Company does not proceed so smoothly as could be wished. On the 20th instant the "Calabria," which is engaged upon the work, arrived in the Tourane Bay, and on the 21st an attempt was made, with the aid of several French vessels, to place the cable ashore at Thuan An, but the sea was so high that the bar at the mouth of the Hué river could not be crossed. Another attempt made the following day was equally unsuccessful."

ELECTRIC LIGHTING FOR HOTELS.—We briefly mentioned in a recent note that the Royal Hotel, Blackfriars, was to be partially lighted by electric lamps. This has now been done. There are four Siemens arc lamps in the large dining room, while the reading room is lighted by sixty-three Swan lamps. The ladies' drawing room also is lighted by twelve Swan lamps. The current is supplied by a Siemens dynamo driven by a 16 horse-power Otto gas engine. The work has been done by Messrs. Siemens Brothers and Co., of 12, Queen's Anne's-gate, Westminster, under the superintendence of the architect of the hotel, Mr. E. A. Gruning.

OVERHEAD WIRES IN THE PROVINCES.—The Winsford Local Board having declined to allow the erection of telegraph poles and wires through their district, which lies in the line of the proposed new service from London to the north, an action has been commenced against them by the Postmaster-General. The defendants object to the poles as dangerous and unsightly, and ask that the wires should be carried underground. It is stated that this is the first refusal that has been met with by the Post Office in the course of erecting 900 miles of wire. It will be recollected that at Peterborough a few days since, in a somewhat similar case, when a surveyor figured as the defendant and the Post Office as the plaintiff, the verdict was for the plaintiff.

MARKET OPERATORS.—In a recent article our contemporary *The Standard* says:—"What, however, counts more than anything else against the future progress and ultimate triumph of the electric light is the speculative element which has, thus far, been mixed up with the commercial side of it. It has been the prey of the market operator more than any other form of enterprise of recent date, not excepting gold mines. The operator is rarely or ever anything but a source of trouble to the enterprise he undertakes to assist. He is least of all a good friend to a new invention, because his object is not the development of an industry of any kind, but an immediate profit. It is no part of his business to find the means with which to pursue costly and protracted scientific investigations."

THE JABLOCHKOFF COMPANY.—A petition for the winding up of this company was presented on the 21st January by Messrs. J. Edmundson and Co., of Great George-street, S.W., and will be heard before Mr. Justice Pearson to-day (Saturday). On the same day another petition, presented by Mr. Davitt Hulett, of High Holborn, W.C., with the same object, will also be heard. The directors of the company have issued a circular to the shareholders recommending its reconstruction, and for this purpose they have convened a meeting to pass the necessary resolutions for voluntary liquidation. It is stated that under the scheme of reconstruction the present shareholders will retain a substantial interest in the company, while provision will be made to satisfy the creditors in full.

THE TELEPHONE IN ABERDEEN.—We have received a copy of the list of subscribers to the Aberdeen exchange of the National Telephone Company. Since the issue of the last list, in September, 1883, some forty or fifty new subscribers have been connected up. The total number of subscribers is now 293, and there are 13 private lines. Together these represent nearly 180 miles of wire. The longest line at present erected by the company is that to Stoneywood works, which measures $5\frac{1}{3}$ miles; but a longer one is being put up to connect the Culter Paper Mills Company, of Culter, with the exchange. This line will be over 8 miles long. The list is very neatly, not to say tastefully got up, and we notice that the Aberdeen exchange is still under the management of Mr. J. D. Miller.

IS "H" A NEW KIND OF CEMENT?—We are from time to time amused by the attempts of the ordinary newspaper reporter to describe things electrical, and we think the following will take no mean place in the history of ignorance:—A few days ago a description of additions to Messrs. Crompton's works at Chelmsford was given in a local paper. One of these additions is a small magnetic observatory fitted up to obtain the value of "H" at Chelmsford. This value is, we believe, to be used in the calibration of the Crompton-Kapp measuring instruments. The sapient reporter tells us that "upon the horizontal component of the earth's magnetism will be erected a large powerful tangent galvanometer," &c. Evidently the reporter imagines that the "horizontal component" is a new kind of cement-concrete, or something upon which to erect a substantial superstructure.

MORNING GLOW.—The following information, communicated to the *Daily Telegraph*, together with our note of last week on Professor Guy's experiences at Perpiguan, in France, may be interesting. Our contemporary says:—"A correspondent writes from Budleigh Salterton, Devonshire, relative to the recent gales: 'About 2:30 on Saturday morning the storm calmed for a short time, when a curious phenomena occurred. The eastern and south eastern horizon became illuminated with a bright light, similar to that which sometimes precedes the early rising sun, while above the light, extending to the zenith, was a dense dark cloud, from which shot forth vivid flashes of lightning, accompanied by heavy peals of thunder and pelting rain. The storm continued until the evening, the day closing with a beautiful aurora, the illuminated part of the sky being surrounded by dark clouds, from which also shot flashes of lightning.'"

UNIVERSITY COLLEGE, NOTTINGHAM.—At the formal opening of the technical schools in connection with this college by Sir Frederick Bramwell, on Thursday, Jan. 24th, the workshops were illuminated with Swan lamps, arranged in series of three, the current being supplied by a Ferranti machine (with Siemens's exciter) lent for the purpose by the Ham-

Digitized by Google

mond Company. The Ferranti machine was driven by two 2½in. single belts from a countershaft carrying two 60in. wrought-iron pulleys, made by Hudswell, Clarke, and Co., of Leeds. The countershaft was driven by a 6in. double belt from the flywheel of a 20 horse-power Robey engine, the driving pulley on the countershaft being 15in. in diameter. The lights were perfectly steady, and the installation was in all respects satisfactory. Three lamps, silvered over their upper halves by Messrs. Abbey and Co., of White Hart-street, in accordance with the patent of Messrs. Lorrain and Maher, were very much admired.

Electric Lighting in Newcastle-on-Tyne.—Messrs. Tangye Brothers, the well-known engineers, of 8, Nicholas-buildings, Newcastle-on-Tyne, have adopted the incandescent system for lighting their machinery show room. Up to the present time this room has been lighted by gas, and the result has been that the firm have suffered great annoyance from the rust that has collected on the machinery, due to the condensation which invariably follows the use of gas. To avoid this Messrs. Tangyes have adopted the incandescent system. The show room is now lighted by means of four pendants, each carrying five 20 candle-power Swan lamps. Ten similar lamps are also used to light the offices. The current is supplied by a Siemens self-regulating dynamo, driven by a Tangye "Soho" engine, mounted on a "colonial" boiler. The whole installation has been carried out with success by Messrs. J. H. Holmes and Co., of 67, Westgate-road, Newcastle-on-Tyne, under the personal supervision of Mr. J. H. Holmes, A.M.I.C.E.

Electric Lighting in Newspaper Offices.—The offices of the *Irish Times* were lit up on Thursday week by the incandescent system, nearly 200 Swan lamps being used throughout the premises. The current is generated by one of Siemens's new type alternate current machines, the novel feature in which is that the helix is composed of straps or ribbons of copper, instead of coils of wire, as in the older form of alternate machine. An upright shunt-wound dynamo is also used as an exciter, and at 1,500 revolutions the alternate machine gives a current of 180 amperes under an electromotive force of 45 volts. The machines are driven from a countershaft, the latter being coupled up with two 12 horse-power gas engines, so that one or other of the engines may be used at pleasure. Each lamp is provided with a switch, so that the light may be turned off or on as required. Safety plugs are also provided. The installation has been fitted up by Messrs. Siemens, under the personal superintendence of Mr. J. Angelo Fahie, M.S.T.E. and E., of Dublin.

The Bell Patent in America.—The *Standard's* New York correspondent telegraphing last Sunday night, said:—"The Stock of the American Bell Telephone Company fell yesterday from 180 to 145 within 30 minutes. Later in the day, upon the largest sales known taking place, it was quoted successively at 134, 145, and 160, and it closed at 152. The cause of these fluctuations was the prevalence of conflicting reports as to the decision of the case of the Bell Company *v.* the Overland Company. The fact is that no decision has been given, the Court having reserved it pending the decision in the case of the Bell Company *v.* the People's Company, which deals with fundamental points, and involves the question of priority of invention now disputed between Bell and Drawbaugh. The fluctuations measure the public estimate of the validity of Drawbaugh's claims, and their appreciation of the fact that his success would be fatal to the existing monopoly. If it was freed from that obstruction the telephonic art would enter upon a new era of world-wide usefulness. The financial bearings of the subject are therefore insignificant, compared with its popular and scientific aspects."

Anglo-American Telegraph Company.—At a meeting of the Board of Directors of this company, held on Friday week, it was resolved (after placing £37,500 to the credit of the renewal fund for the quarter ending 31st December, 1883) to recommend to the proprietors at the next half-yearly general meeting of the company, to be held on the 8th February, the declaration of the following dividends, all free of income-tax:—1. A balance dividend of 20s. per cent. upon the Ordinary Consolidated Stock for the year ending 31st December, 1883. 2. A balance dividend of 30s. per cent. upon the Preferred Stock for the year ending 31st December, 1883. 3. A first and final dividend of 10s. per cent. upon the Deferred Stock for the year ending 31st December, 1883, all payable on 9th February. After paying the foregoing dividends, there will be a balance of about £600 to be carried forward to the next account. The above dividends, together with those already paid, will amount to 3¼ per cent. on the Ordinary Consolidated Stock, 6 per cent. on the Preferred Stock, and ½ per cent. on the Deferred Stock, for the year 1883. The register of transfers will be closed up to the 8th February, both days inclusive.

A Portable Soldering Furnace.—We have had a sample of a handy little soldering furnace sent us, which is intended for use on housetops, or other positions where the usual process of heating a soldering iron would be inconvenient, or, where no fire was obtainable, impossible. The furnace consists of a small copper reservoir for methylated spirit, with a couple of wick-holders projecting from its upper side. Over this fits a hinged cap, also of copper, the top of which consists of a gutter, in which the solder is placed, with perforations on either side to keep up a draught. This cap is fitted with hinges, and can be thrown back to light the wicks, after which it can be closed and fastened with a spring catch. The solder melted, the joint to be soldered is placed in the trough, and in a few seconds the work is done. The whole apparatus can be held in the hand by means of a handle projecting at right angles, and securely fastened to the reservoir by an iron band. We have not had an opportunity of testing the capabilities of this portable soldering furnace as yet; but it seems, to judge from the specimen before us, to be handy and of practical utility. It should be particularly useful to linemen as well as to electric light *employés*. The London agents are Messrs. Buck and Hickman, of 280, Whitechapel-road, E.

Pyro-Electricity of Blende, Sodium Chlorate, &c.—Messrs. C. Friedel and J. Curie have investigated this subject, and the following is the result of their researches as given in the *Comptes Rendus*, and abstracted for the January number of the *Chemical Society's Journal*:—"Crystals of the cubical system which show tetrahedral hemihedrism behave like crystals of the hexagonal system. If heated or cooled regularly, *i.e.*, so that the expansion or contraction is equal along all the axes of hemimorphism, there is no development of pyro-electricity, but if the heating or cooling is irregular, so that tension is produced in different parts of the crystal, then electricity is developed. These phenomena have been observed with blende and with sodium chlorate. Mallard has shown that boracite at ordinary temperatures belongs to the rhombic system, but at about 265° its form changes to one belonging to the cubical system. The authors find that if a plate of boracite cut parallel with one of the tetrahedral faces is heated at 300—320° for some time and then allowed to cool regularly, no electricity can be

Digitized by Google

detected until the temperature falls to about 265°, but at this point there is a considerable development of electricity, which gradually diminishes in intensity, and eventually changes in sign. It appears, therefore, that when boracite cools regularly it only becomes pyro-electric at the point at which it ceases to belong to the cubical system."

THE PILSEN-JOEL COMPANY.—This company have, during the past year, fitted up their lamps at Messrs. Lewis and and Co.'s, Liverpool; the Art Schools, South Kensington; Messrs. Gibbs, Son, and Co., Milton-street; Messrs. Falder and Co., Stockport; Messrs. Hopkins and Peggs, Shoreditch; Messrs. Kruzinski, Shoreditch; the Tower of London, the Junior Army and Navy Stores, and in a portion of the city of Stockholm. They have just completed a most important incandescent and arc installation at the mills of Messrs. Baxter and Son, of Apperley Bridge, near Leeds. This installation consists of 300 incandescent and four arc lamps, the whole of the apparatus, lamps, dynamo-machines, &c., having been manufactured at the Pilsen Company's Works, Kentish Town. The company have recently introduced their system in Exeter, on the premises of the *Devon Evening Express*; their light may also be seen on the premises of Messrs. Hirder and Sons, Plymouth. The Joel semi-incandescent and the Gatehouse incandescent lamps have been introduced into New Zealand by Messrs. Ross and Glendenning, and in Australia the Pilsen lamp has been fathered by the Australasian Brush Company. It will be remembered that the Pilsen Company have obtained a provisional order for lighting an important area in St. Giles's district, Holborn, and that the company established a lighting centre in that district a year and a half ago, and the lighting has given great satisfaction to users in that immediate neighbourhood. We understand that the company have recently tendered for the lighting of the Crystal Palace, Sydenham, experience having proved that the success of any important public exhibition or entertainment depends largely on the use of the electric light.

THE GALES.—The damage caused to telegraphic communication by the succession of gales which have occurred since Friday, the 25th January, has been serious and widespread. From Marseilles, in the south of France, to the extreme north of Scotland we hear of communication interrupted. A correspondent of a daily paper, telegraphing on Sunday last, stated that for eighteen hours Paris had been without telegraphic communication excepting with Rome, and in that case only by one wire. At the time of telegraphing, viz., Sunday night, he stated that out of the many hundred wires converging in Paris from all parts of the world only nine were in operation. He probably forgot the underground cables, however. In the United Kingdom the wreck has been universal and complete, even now many circuits are broken, and it will be some few days before everything is in working order again. Dover experienced the full force of the storm on Saturday, and was cut off entirely from neighbouring towns. The Dover-Ostend cable was also interrupted. In London the wires appear to have stood very well, and we have only heard of one or two breakages. The greatest ruin appears to have occurred in the north of England and Scotland, where communication was entirely stopped. Indeed, the damage was so great that we doubt if its extent has been fully ascertained even yet. The Caledonian Railway Company had at least thirty miles of wire down, poles and all, and to this must be added another twenty miles on the North British line. The North Eastern Railway also suffered severely. The consequence of all this was that the Post Office communications with Scotland were entirely stopped on Saturday, and were not wholly restored at the time we went to press. The gale was accompanied by thunder and lightning, but the latter does not appear to have done much damage either to property or life.

WHEELER V. THE UNITED TELEPHONE COMPANY.—This case came before Mr. Justice Watkin Williams and a common jury in the Queen's Bench Division of the High Court of Justice on Saturday last. The plaintiff brought an action against the defendants for breaking and entering upon land which he occupied at Stratford, and erecting telephone posts upon it without his permission.—The defendants, whilst denying liability, paid £5 into court as sufficient satisfaction. —Mr. Fillan was counsel for the plaintiff, and Mr. Cock for the defendants.—The plaintiff said when the defendants' men came to put up the posts on his farm he went to protest against the proceeding; that thereupon they asked him "Who are you?" and that on his stating he was the tenant of the farm they said they did not care. They had authority to erect the posts on the land, and would throw him and his servants into the river if they interfered. The defendants' men denied having used any such threat.—Mr. Cock said his clients proceeded to erect the posts by the authority of the East London Water Works Company, believing at the time that this company was entitled to give it. Finding afterwards that this authority did not extend to the land where some of the posts were being erected on the plaintiff's farm, which was held of the Great Eastern Company, the defendants desisted, had one of three posts which had been put up removed, and undertook that if plaintiff would allow the posts to stand and some more to be erected they would pay him a yearly rent of 7s. 6d. for each, and be responsible for any injury that might arise from there presence there. The offer had not been accepted, and the defendants met the action by paying the £5 into court.—In answer to the judge, Mr. Cock said he was prepared to admit the trespass, so that the only question would be as to whether the £5 paid into court was sufficient.—The judge was of opinion that it was sufficient, and the result was a verdict for the plaintiff on the question of his title to resist the erection of the posts, which the defendants in their pleading had disputed, and a verdict for the defendants in regard to the sufficiency of the compensation.

COAL CUTTING BY ELECTRICITY.—The latest novelty in mining machinery is an electrical coal cutter, or, to describe it more accurately, a coal cutter of the ordinary type driven by electricity. "It is obvious," says Mr. G. G. André, in the last number of the *Colliery Guardian*, "that electricity can be readily applied to this purpose, and it is strange that we have not heard of the application before. The advantages afforded by wires over pipes for the transmission of the motive agent are so clearly apparent that they need not be pointed out. The electric motor is of extremely simple construction, and is designed for the circumstances under which it will have to work. Thus, one of the conditions of success has been fulfilled, and it is the one over which inventors usually stumble. In many cases the inventor is not what is called a "practical" man, that is, one who is practically acquainted with the work which the machine is designed to perform. As a consequence, it is defective in some details, and, failing in consequence to satisfy some one of the conditions of practice, it is condemned and thrown aside. Many a useful invention has been lost in this way that in competent hands might have been made a success. The electric coal-cutter, if reports are to be believed, will not fail on this account, for it is in the hands of men who know well what they have to deal with. It is said to be an

Digitized by Google

American invention modified by a French mining engineer. Curiosity has been greatly excited respecting this machine, and the results of the trials about to be made are awaited with interest. It is easy to foresee that however satisfactory the machine may perform its work, it cannot be used in a fiery atmosphere, on account of the inevitable sparking at the brushes, or other moving contacts. This fact will limit its application to non-fiery workings. Another obvious application of electrical power to mining purposes is to haul coal from dip workings. Portable hauling machinery of this nature could be constructed that would be perfectly reliable in action. This is a point to which attention might profitably be directed. There have been some attempts made to employ electricity as the motive power for rock drills. These attempts have failed for the reason I have pointed out in the preceding paragraph. If electricity is to be successfully applied to this use, it must be by means of a rotary motion. A percussive action may, of course, be derived from this; but it is a necessary condition of success that the motor revolve. Jalorimek's drill, which I have recently described, might be very effectively driven in this way. But whatever the construction of the motor may be, its moving parts at least must be protected against the water and the grit to which it will be exposed under ground. It should not be difficult to enclose the whole of the motor within a metal casing, and such a shield would not only protect it against grit and water, but would render it capable of bearing the rough usage it cannot escape in the hands of miners."

Electricity v. Gas at Berechurch Hall.—In our issue of December 2, 1882, we gave a description of the lighting of Berechurch Hall, the residence of Mr. O. E. Coope, M.P., by incandescent lamps, and in our issue of January 20th following we quoted in our "Notes" a letter from Mr. Coope to *The Times* which went very fully into the question of the relative cost of gas and electricity in this particular instance. According to this letter the cost of electricity for lighting the above Hall came to £1,470 8s., against £1,333 18s. for gas, but Mr. Coope now says that £20 should be added to the £1,470 8s. for stores, making it £1,490 8s. These figures were based upon the results of three months' working, so far as electricity was concerned, and Mr. Coope now writes to *The Times* (January 25th) giving the actual results of the year's working. We regret that we cannot reproduce his interesting letter in full, but the pressure on our space prevents our giving any more than an abstract of its contents. Mr. Coope states that there has been no mishap during the year with the exception of the belt slipping three times, causing but a few minutes' delay, and a drunken engine driver, who had to be summarily dismissed. The lights have been steadier than gas, and are giving 20 candle-power in place of 18 candle-power, the maximum light they were estimated to give at the outset. The number of hours of working has also been exceeded; it was estimated at 1,150, but has amounted for the year to 1,823. Mr. Coope recapitulates the figures given in his last year's letter as follows:—"Estimated annual expense of the electric light, 200 18-candle lamps, each working 1,150 hours per annum: Coal, at 20s. per ton, £38 10s. 1d.; engine driver, at 30s. per week, £78; renewal of lamps, 153 at 5s., £38 5s.; depreciation, 10 per cent. on cost of machinery, £74; ditto, 5 per cent. on conductors, £4; total, £232 15s. 1d.; or, say, one farthing per 18 candle-power lamp per hour (the real figure being ·97 of a farthing)." He then gives the actual cost for the past year as follows:—"Coal (small, at 13s. 6d. per ton, mixed with coke at 18s. per ton), £90; wages (engine driver and lad), £79 14s.; renewal of lamps, 300 at 5s., £75; oil, cotton waste, &c., £20; repairs, £5 8s. 1d.; sundry small items and expenses, £7 16s. 8d.; depreciation, 10 per cent. on cost of machinery, £78; do. 5 per cent. on conductors, £4; total, £359 18s. 9d., which is just under a farthing per 20 candle-power lamp per hour (the exact figure being ·95 of a farthing)." He then goes on to say: "It will be seen, therefore, that in the estimate contained in my letter of last year I overstated the probable expense. I have not only kept the installation in repair, but I have actually placed a sum by of £82, which annual amount will enable me in less than nine years to entirely renew the engine and electrical machinery, taking advantage of any improvements that may have been made in the meantime; or, in the event of the machinery still being in good working order, to entirely recoup myself for its expense. My engine does a large amount of pumping, and I calculate that on this head alone it is saving me at the very least £60 per year. The renewal of lamps (300) may seem large, but there is little doubt that the late engine driver by his carelessness weakened the carbon filaments of many of these, and caused them to break sooner than they would otherwise have done. However, this is an item I hope to see reduced this forthcoming year, and as time goes on to shrink into a very insignificant amount. I am also hoping to reduce the fuel charge, but it must be remembered that Berechurch Hall is about four miles from the nearest railway station, which is at Colchester. Speaking of the lighting in my letter of last January, I said, 'The result has been a success that has exceeded my anticipations. The light is quite as easy to manage as gas, while the softness, the purity, and the agreeableness are such that a return to any other method of illumination would be now quite out of the question. The pictures, books, and decorations have no chance of injury. The ceilings and walls remain unsoiled, while the difference in health felt after sitting an evening in a room electrically illuminated and another lighted with gas must be experienced before it can be appreciated.' The whole of which a year's further experience enables me to most emphatically reassert." Mr. Coope concludes by an energetic protest against the common mistake of "bunching" the lights, and states that as a rule single lights are used at Berechurch, those for the dining room and hall being single lamps suspended by silk cords from the ceiling, "producing a charming effect, the lights appearing as if floating in the air." Mr. Coope also says that at present he has not sufficient confidence in accumulators to adopt them. We may mention that before obtaining a tender for this work Mr. Coope called in the assistance of Mr. Musgrave Heaphy, C.E., of the Phœnix Fire Office, and got him to draw up a detailed specification in which particular regard was had to fire risks. The work was carried out to this specification by Messrs. R. E. Crompton and Co., of Chelmsford, and the excellent working of the whole installation shows how well everything was done. In a subsequent issue of *The Times* Professor George Forbes calls attention to the fact that by employing professional assistance Mr. Coope saved himself a great deal of annoyance and trouble; and thinks that if "independent professional advice" were more often called in by those intending to use the electric light, it would save them from much "useless expenditure and the annoyance of failure." He states that he knows of one company even who "contracted to light the streets of an important town, and did not seek the opinion of their consulting engineer, a well-known electrician." This remissness cost them £10,000, or at least they owned to that amount. Mr. Forbes thinks it "was probably more."

## CURRENT ENERGY.—XIII.

BY OLIVER HEAVISIDE.

(CONTINUED FROM PAGE 201.)

*Chemical Contact Force.*

We now approach one of the most interesting subjects in the whole of electrical science, on which there has perhaps been more debate than on any other of its branches. He is a learned man who is fully acquainted with all the details in the history of the matter. But one may not be therefore made wise; on the contrary, one may easily become utterly confused in the attempt to reconcile the multitude of facts and hypotheses, especially as the observations are mostly only qualitative. He may wish to obliterate all that has been done, and start afresh in the unbiassed state of mind accompanying perfect ignorance.

Put any two metals in contact with one another, but otherwise insulated; they are said to acquire different potentials. That they are apparently at different potentials is made certain by the modern electrometric measurements, using no finger contacts or multiplying machines. Thus, zinc and copper in contact apparently differ in their potentials by about ·75 volt. Professors Ayrton and Perry found this to be so constant that they used it as a standard of comparison in their observations on the apparent differences of potential of other metals in contact. It is proved that when zinc and copper are put in contact, the zinc becomes positively, the copper negatively electrified, and that they act inductively on other conductors just as any two conductors similarly charged would.

If we join the zinc and copper by a wire of some other metal, say iron, instead of making immediate contact, just the same thing happens; the difference of potential is ·75 volt as before. This applies to all pairs of metals, whence follows the "summation law." If metals A and B in contact apparently differ in their potentials by $x$ volts, and A and C by $y$ volts, then B and C will differ by $x - y$ volts.

However, it is merely inferential that zinc and copper in contact really differ by ·75 volt. But assuming provisionally that such is the case, it follows that since in a state of electrical equilibrium the whole of the zinc is at one potential, and the whole of the copper also, there is an E.M.F. of ·75 volt acting at their junction from copper to zinc; this being required to balance the supposed difference of potential. If so, if we pass an electric current from any source across the junction, there will be, by elementary principles, a continuous absorption of energy when the current goes from copper to zinc, and generation in the converse case, amounting per second to ·75 × strength of current. Or, make a closed circuit of any number of metals and a battery; there will be similar absorptions and generations of energy at all the junctions, meaning by absorption that energy is taken in by the current from some source which—electrically speaking—may be called external, and by generation that energy is given out by the current, or through its mediation.

But there is no evidence of any such relatively enormous conversions of energy going on at metallic junctions. The known thermo-electric E.M.F.'s are of such inferior strength as to be almost of a different order of magnitude. The source of energy is heat, *i.e.*, the energy of molecular agitation. There may be other small conversions of energy, but certainly none able to account for an E.M.F. of ·75 volt between copper and zinc, or ·6 volt between zinc and iron.

The thermo-electric forces being, then, so very small compared with the apparent contact forces now considered, we may neglect them altogether, in order to save continual reference to them and small corrections. Copper and zinc, then, when placed in contact, are necessarily at One potential.

It follows that if they were uncharged before being put in contact, and not in a field of electric force, they must have been at Different potentials. For, on contact, electricity passed from copper to zinc, reducing them to the same potential. But, having been, as stated, uncharged in the first place, and not in a field of force (or, say simply, neither showing any signs of electrification), the air being then all at one potential, and the potentials of the copper and zinc differing from one another, must be different from that of the air, as thus defined. Taking the air potential as zero, and that of the copper separately insulated as $(-x)$ volt, that of the zinc is $-(x + ·75)$ volt. So far we do not know whether $x$ is positive or negative, but we take it as positive here for convenience of statement. Thus a piece of uncharged zinc insulated in air has its potential $(x + ·75)$ volt below that of the air, and a piece of uncharged copper insulated in air is also at a lower potential, but by a smaller amount, namely $x$ volts. This requires that there shall be, over the whole zinc surface, an E.M.F. of strength $x + ·75$ volt acting from zinc to air; and similarly over the whole copper surface an E.M.F. of strength $x$ volt from copper to air.

Electricity, in conductors, is subject to the same law of continuity as an incompressible liquid. There cannot be current entering a certain space without there being at the same time an equal current flowing out of that space. At the surface of conductors electricity was once supposed to accumulate. Maxwell extended the law of continuity to the surrounding dielectric. There is great advantage in this view in facilitating conceptions. We may imagine an incompressible liquid filling *all* space, perfectly free to move by the slightest force in certain regions answering to pure conductors, with no tendency to return when displaced, but always meeting with resistance proportional to the velocity. Also perfectly free to move in the rest of space answering to a pure dielectric, and without frictional resistance, but now only elastically displaced, so that there is a force of reaction called into play proportional to the displacement, which will make the displacement subside when the force that produced it is removed.

Replace the material liquid by an imaginary something called electricity, filling all space (not the electricity of the mathematical definition, but capable of becoming it by displacement), let it be free to move in conductors when acted upon by electromotive force (answering to real force when the subject is a real fluid), but only capable of elastic displacement in the dielectric, and we may transfer results from one case to the other. We may remark, in passing, that the quasi-fluid cannot be really matter, because that would require electromotive force to be ordinary mechanical force.

If to the surface enclosing a portion of the material liquid in which there is no reactive force, but outside which there is, we apply uniform normal pressure or tension, the liquid is not moved, because the forces balance, but the pressure within is increased or decreased by an amount equal to the applied surface pressure or tension.

In the electric case, the uniform E.M.F. $x + ·75$, acting normally outward from a piece of zinc insulated in air, lowers its electric potential below that of the surrounding air by the amount $x + ·75$, but cannot displace electricity. Similarly the E.M.F. $x$, acting normally outward from the copper surface, lowers its potential below that of the air by the amount $x$. But the moment the copper and zinc are touched, we substitute at the place of contact metal for air; the force $x + ·75$ is removed from a portion of the zinc, and the force $x$ from a portion of the copper surface; the differential force ·75 volt acts; there is a current from copper to zinc, from zinc to air, and from air to copper, which is stopped by the force of reaction of the electric displacement in the dielectric. The zinc and copper are reduced to the same potential; let this be $y$. Then, in the new state of equilibrium, the potential rises from $y$ to $y + x + ·75$ in passing from the zinc to the air, then falls continuously along the lines of electric displacement in the air till the air outside the copper surface is reached, where it equals $y + x$, and then falls by the amount $x$ in passing into the copper, where it is $y$, the common copper and zinc potential.

This may seem unnecessarily diffuse, but the importance of the subject, and the difference of the above from views in general acceptance demand a somewhat amplified statement.

The reason of the summation law readily follows. For let the zinc and copper, previously insulated, be joined by an iron wire. This, if insulated and free from charge, will have its potential lower than that of the air surrounding it by $x + ·60$ volt; or, $x + ·60$ is the E.M.F. from iron to air. In contact with the copper only, when their potentials equalised, the field of force in the air would show a difference of poten-

Digitized by Google

tial along any line of force of ·60 volt, and in contact with the zinc only, of ·15 volt, the iron being positively electrified in the first case, and negatively in the second. But when the iron wire is intermediate between the zinc and copper, the force $x + ·60$ from iron to air, since it can now draw electricity both ways, from the copper and from the zinc, can have no influence in altering the difference of potential between the air just outside the zinc and just outside the copper, although altering the actual potentials relative to the original potential of the air. If $z$ is the final potential of the three metals, those just outside the copper, the iron and the zinc are $z + x, z + x + ·60$, and $z + x + ·75$, with a fall of ·75 as before through the air from the zinc to the copper surfaces.

It may be remarked that the field of force is perfectly determinate with any number of metals in contact, between each of which and the air there is a given E.M.F. The bounding surface of the dielectric has then everywhere a given potential (+ a constant), and by Green's theorem this is sufficient to fully determine the distribution of force. Of course mathematical difficulties prevent the practical solution in general.

In the above we have, for simplicity, supposed the metals to be pure and homogeneous, and to have clean surfaces. Some little difference is made when there are surface impurities. The nature of the effect may be readily seen. Start, for example, with a piece of absolutely pure zinc, and put a small particle of iron on its surface. The iron and zinc are at once reduced to the same potential, with positive electrification of the zinc and negative of the iron, and a fall of potential of ·15 volt through the air. Yet there will be no apparent electrification whatever, for the field of force can be only sensible quite close to the particle of iron, so that we cannot get at it. The air all round the zinc mass will be practically at one potential. If we enlarge the iron particle the field of force extends and becomes sensible at sensible distances, and so with further enlargement we can get sufficient separation of the parts of air at the extreme difference of potential to affect the electrometer inductively.

Similarly, when there are, as in commercial zinc, innumerable foreign particles exposed to the air, side by side with the zinc and in contact with it, there are innumerable local fields of force quite close to the surface set up by the unequal E.M.F.'s. But at a sensible distance from the surface there can be no appreciable force, the air potential will be there unaffected, and the zinc will appear uncharged.

Put this mass of impure zinc in contact with a mass of copper—it may be also impure—then, besides the complex local fields close to the surface there is the extended one which can influence the electrometer. The difference of potential cannot be so great as with perfectly pure zinc and copper, the impurities acting to reduce it.

Now change the medium. Let zinc and copper be in contact not in air, but in water, with a little acid to facilitate electrolysis; from being in a medium in which only elastic displacement can happen, let the zinc and copper be wholly immersed in an electrolyte. The surface E.M.F's are now probably not the same—it is very unlikely that they should be—but there they are. Instead of their producing a mere momentary current, we now have a continuous current from zinc to liquid, liquid to copper, copper to zinc. The two metals are not now exactly at one potential, owing to the current, but practically all the fall of potential is in the liquid. The lines of force, which are of course also the lines of flow of current, are, when the sides of the vessel containing the liquid are sufficiently remote, distributed in the same manner as the lines of force in the corresponding case with air as the medium, though of course they become considerably altered if the vessel is small, the current being forced to be tangential at its sides.

The local superficial fields of force have now great importance, for there are naturally local currents to correspond between the zinc and its impurities with consequent waste of energy; waste in not being externally available. This is the same when the zinc is alone in the liquid. The purer the zinc the more slowly is it burnt in acid. Absolutely pure untarnished zinc would last for ever, owing to the balance of forces, but the least impurity getting on the surface would start galvanic action.

If a copper wire joins the zinc and copper, all being still wholly immersed, circumstances are not materially altered; the current goes from the zinc to the copper (say plates now), and also to the copper wire through the liquid and back through the wire; the current in the wire, however, is not everywhere of the same strength. But lift the wire out of the liquid together with that portion of the zinc plate to which it is attached, and the whole current (not counting the local currents) returns by the wire outside the vessel, and we have a full-blown galvanic cell.

The new E.M.F. introduced by the new contacts, viz., between the zinc and air, and the copper and air, do not in any way alter the integral E.M.F. in the circuit, nor can any difference of potential between the liquid and the air. The metals in connection may be nearly at one potential, or may differ by nearly the full E.M.F. of the cell, according to the resistance of the external wire. There is a large rise at the zinc-liquid surface, and a fall of much smaller amount at the liquid-copper surface, the excess of the rise at the zinc over the fall at the copper being equal to the available E.M.F. of the cell. But in other galvanic arrangements, as when there are two fluids, the E.M.F.'s and changes of potential become more complex.

The absorption of energy is at the zinc surface where the current goes with the E.M.F. there. The evolution is at the copper surface where the current goes against the E.M.F. there. The excess of the former over the latter becomes heat in the circuit.

At the zinc surface we know there is oxidation of zinc, and the supply of energy is readily accounted for. The heat which would have been produced locally if the zinc were burnt in oxygen now turns up in all parts of the circuit, through the intervention of the unknown electric agency, and the artificial disposition of conductors and insulators we have made.

The evolution of energy at the copper surface is more obscure. There is a local development of heat independent of the frictional heat in the circuit. The heating of galvanic batteries has not been fully investigated.

Regarding the cause of the E.M.F.'s, next to nothing is known. Separated zinc and oxygen have potential energy, they tend to unite, and in the act of union a store of energy is set free. At the same time there is E.M.F. from the zinc to the oxidising agent. But why zinc and oxygen should unite, or why E.M.F. should accompany the action I have not come across any intelligible explanation. And I do not expect it.

But the known transformation of energy taking place at the zinc surface in our galvanic cell, together with the similarity of electrical conditions, enables us to conclude with a tolerable amount of certainty that the source of the electrostatic energy which is set up when zinc and copper are put in contact in air is oxidation of the zinc. The amount of oxidation is, of course, very small—infinitely unrecognisable. This will be evident on remembering what a large quantity of electricity must pass before any visible consumption of zinc takes place in the cell, or even before enough is consumed to be detectable by the most delicate chemical balance. In the air case the action is stopped in its very birth by the elastic reaction of the electric mechanism. The facts observed long ago by Sir W. Thomson confirm this conclusion regarding oxidation. The difference of potential is greatest when the zinc surface is clean—that is, in the best state for oxidation—and when the copper surface is already oxidised, and therefore in the worst state, amounting then to about 1·1 volt instead of only ·75 volt.

## ON THE MEASUREMENT OF ELECTRIC CURRENTS AND POTENTIALS.*

BY SIR WILLIAM THOMSON, F.R.S.

In this communication, after referring to the electrometer as being when available, in one form or other, the most proper instrument for measuring differences of electric potential (inasmuch as it disturbs the difference of potential to be measured not at all, because the insulation of the insulated part or parts may be made practically perfect), it was shown that the functions of an electrometer can, for many practical purposes, in a thoroughly satisfactory manner be performed by means of a galvanometer of high resistance. Thus galvanometers of from 200 or 300 to 30,000 ohms resistance can be very conveniently used for measuring differences of potentials of from one to 600 volts, provided that in each case the coil is not heated by the current produced in it so much as to cause more than allowable error by augmentation of its resistance. To obviate the need for a temperature correction on account of difference of atmospheric temperature, it is necessary, for fairly satisfactory accuracy in ordinary practice, to have the coils of potential galvanometers made of German silver wire instead of copper. In cases, however, in which the sensibility obtainable by copper is desired, the galvanometer coils may be made of copper wire, but the proper temperature correction, amounting approximately to 39 per cent. per degree centigrade, must be carefully applied. But there is no need for the sensibility obtainable by copper coils in almost any of the practical applications of electricity except telegraphy; and for general use in scientific laboratories, or in electrical factories, or in connection with electric light installations, the potential galvanometer ought to have its coils of German silver wire, because the increase of resistance for this alloy is only about ·04 per cent. per degree centigrade, and is less than for any other known and practically available metal.

The author showed a new form of potential galvanometer, with four German silver coils acting on the two needles of an astatic combination hung by a single silk fibre. The astatic combination has for most practical applications great advantage over the single needle galvanometer in respect to liability to disturbance by magnets in its neighbourhood. The new form of astatic needle galvanometer, whether for current or potential, may be used even in close proximity to a dynamo machine without being sensibly disturbed. In this instrument the two needles of the astatic combination are controlled by two equal magnets, or combinations of magnets, symmetrically arranged and adjustable for zero; but, in the instrument which the author prefers, not adjustable in respect to power. This last adjustment, which is used in one of the forms of the new instrument, has not been found very convenient, and is at present, at all events, liable to suspicion of inconstancy. The method which the author at present prefers for adjustment to any desired sensibility is by the use of adjustable resistances placed in series with the coils of the galvanometer. A very convenient and ready appliance of this kind constituted part of a complete instrument shown to the society, and designated by the author a long-range potential galvanometer. After many years of trials and anxious thought the author had come to prefer for practical purposes the use of a standard Daniell cell to any other means hitherto realised for standardising a potential galvanometer. Accordingly he has made, to be used in connection with the new galvanometer, a convenient form of a standard Daniell cell.

A specimen of the cell was shown to the society. It consists of a shallow rectangular tray of sheet copper, about 15 centimetres square, and having vertical sides about 5 centimetres high. Within this tray is placed a zinc plate about 3 mm. thick, and 14 centimetres square, supported firmly in notches of four wooden blocks resting securely in the four corners of the tray. In the centre of the zinc plate is a hole about one centimetre diameter, through which the stem of a filler, long enough to reach the bottom of the tray, passes, which is used to pour into the bottom of the tray a measured quantity of a saturated solution of sulphate of copper. The tube of the filler is very fine, and the capacity of the wide part is sufficient to hold the whole amount of copper solution, which is poured quickly into the filler, and flows slowly out of it in the course of about a minute, so as to spread slowly over the bottom of the cell. The wide part is flat, so as to rest stably on the top of the zinc plate. To set up in action this cell a solution of sulphate of zinc of 1·02 specific gravity is poured into the tray so as to fill it as high up as the zinc plate, and by means of the filler the concentrated solution of sulphate of copper is poured in along the bottom of the tray in quantity sufficient to make a layer of half a centimetre deep.

The instrument, without any resistance added to its coil, is of good sensibility for a single cell. In this condition its coefficient is determined. Then a very simple calculation, or a table of numbers, tells the proper quantity of resistance to be added in order to give exactly the right sensibility with single divisions or round numbers of divisions, corresponding to single volts or round numbers of volts, according to convenience, in the special application for which the instrument is wanted. The user can always, with great ease and with very little expenditure of time, standardise his own instrument in this manner by aid of a standard cell and standard solutions which are supplied along with the instrument.

The pointer by which the deflections are read consists of a light tube of aluminium with one end shaped to a fine edge, by which the deflection is read on a circular scale, divided and numbered, as in the author's graded galvanometers, according to tangents of angles of deflection. As in those previous instruments, the scale is of paper pasted on a horizontal mirror, by aid of which error from parallax is avoided with great ease in taking the readings. To the other end of this pointer is attached about a centimetre of fine platinum wire turned downwards so as to dip about a quarter of a centimetre below the surface of a large flat dish of heavy paraffin oil, with which a little olive oil may be mixed when more of viscous resistance than is given by the paraffin is desired. The author has found that thus a most satisfactory dead-beat effect is obtained, without any sensible error in respect to the position of equilibrium, whether for zero or for the deflection produced by a current. A properly shaped metallic pipette bottle, by which, when the galvanometer is to be moved at any time, the oil may be drawn off from the oil vessel with great ease, carried away without risk of losing any of it, and replaced in the vessel in the galvanometer, is supplied with the instrument. To make the galvanometer itself portable, the frame carrying the steel needles and pointer, which is hung by a silk fibre when the instrment is in use, is let down by aid of a screw so as to hang upon a brass pin passing through a ring which forms part of the framework. In this condition the instrument may be turned upside down or carried about in the roughest way, without the possibility of breaking the silk fibre. To set the instrument in action all that is necessary is to place it in position and level it, and by the screw pull up the upper end of the fibre to its proper position.

A current galvanometer with portable silk fibre suspension, oil vessel to give the dead-beat quality, astatic needles acted on by two circular coils in the main circuit surrounding the two needles respectively, and two magnetic systems of controlling magnets acting symmetrically on the two needles, was shown to the society. This instrument is in all respects exceedingly convenient for the practical measurement of currents, except for the comparative difficulty of standardising from time to time, necessary on account of the inconstancy of the steel magnets. This may be done electrolytically, with sufficient accuracy for most practical purposes, by weighing the deposit of copper from a solution of sulphate of copper, in the manner described at the end of Chap. VII. of Mr. Andrew Gray's book "Absolute Measurements in Electricity and Magnetism," (Macmillan, 1884). The process is, however, somewhat troublesome, and takes a good deal of time. The standardising may be done with much greater ease, by comparison with a standard current meter on the principle of Weber's electro-dynamometer. A very valuable

* Abstract of a paper read before the Philosophical Society of Glasgow, 9th January, 1884.

Digitized by Google

and convenient instrument of this class, Siemens's well-known electro-dynanometer, with its novel and ingenious method for measuring torque by means of a spiral spring acting on the movable coil or arc, which is suspended by a silk thread passing down along the axis of the spring from a fixed point above, and has its two ends dipping in cups of mercury below in the same vertical with the bearing thread, was shown to the society.

Among the instruments shown to the society was also a Siemens watt meter, which is the same as his electro-dynanometer, except that the fixed coil, instead of being of a small number of turns of thick wire in the main circuit, is of a very large number of turns of fine wire connected by its two ends to two points of the main circuit between which the measurement in watts of the electrical activity of the current is to be made. The movable coil is of thick copper, and is, by means of its cups of mercury, joined in series with the main circuit. The instrument is an exceedingly convenient and valuable realisation of an idea which has no doubt occurred to many electricians,* but which so far as the author knew was first published by Prof. John Perry in the *Journal of the Society of Arts* for April 15, 1881, as embodied in an instrument designed by Prof. Ayrton and himself.

The author remarked upon the great want which existed of a name for the unit of conductivity. He repeated a suggestion which he had made in his lecture on "Electrical Units of Measurements," delivered before the Institute of Civil Engineers in London on 3rd May, 1883, that the name "Mho" might be adopted for the unit of conductivity corresponding to the resistance of one ohm. He showed to the society a new instrument which he had designed, and which he termed a mho-meter. It illustrated the great advantages of using the conductivity method in many electric measurements.

This instrument is simply an astatic needle current galvanometer, with the steel controlling magnets replaced by coils of very fine German silver or copper wire, placed perpendicularly to the galvanometer coils proper. The two ends of the controlling coils are put in metallic connection with two points of a conductor, between which the conductivity is to be determined, this conductivity being exceedingly great in comparison with that of the controlling coils. The galvanometer coils proper are connected so that the whole current through them passes through the conductor whose conductivity is to be measured, except the small part of it which goes through the controlling coils. With these connections it is clear that the conductivity to be tested is equal to an absolute constant multiplied into the product of the conductivity of the controlling coils and the tangent of the angle of deflection. One main object of the instrument is to give a ready measurement of the conductivity of dynamo armatures and electric light mains, or of specimens of copper submitted for tests of their specific conductivity. For this application the controlling coils are made of copper, so that no temperature correction may be required (provided the temperature of the galvanometer is approximately enough the same as that of the conductor tested), and the instrument thus made may be called a "Copper Conductivity Meter."

When the object is to measure electric light currents, the controlling coils are made of German silver wire, and are fixed in series with an adjustable resistance, also of fine German silver wire, so wound in a convenient position in the base of the instrument as to exert no electro-magnetic force on the needles. In this instrument the conductivity of the controlling coils, and of the resistance wire in series with them, varies so little with the practical variations of temperature that the conductivity to be measured is for most practical purposes given with amply sufficient accuracy by the tangent of the deflection multiplied by an absolutely constant coefficient. The added resistance may be adjusted to make this coefficient such that one division corresponds to a mho, or a decamho, or a hectomho, or to any other value, within a wide range, which may be found convenient. It may, for example, be adjusted to give deflections at the rate of one division per lamp, and for this application the instrument may conveniently be called a "Lamp Meter."

The author has such an instrument now in use on the lighting system of his house, with varying numbers of from one to 40 Swan lamps, some of the old type, 42-volts, and some of the new type, but of only 84 volts (instead of the 110, which of course would be preferable if it were not for the old lamps, which he has had in use for two years, and which he wishes to keep in use for as many years longer as they will last). It is beautiful to see the pointer moving up two divisions when a pair of the old lamps in series, and by one division when one lamp of the new type is lighted, and falling similarly when any number of the lamps are extinguished; and it is very useful to be able, merely by looking at the instrument, to tell how many lamps are lighted at any time. The inequality of the lamps gives scarcely an uncertainty of one lamp in the whole number when 30 or 40 are incandesced.

The potential galvanometer, which is also always kept on the mains, shows considerable inequalities (checked always, in the course of a few seconds, by the author's potential regulator, with its pair of mutually-geared horizontal cog-wheels dipping on one side or the other, according as the potential is too high or too low, into a hollow centrifugal cylinder of oil rotating rapidly round them), but the pointer of the lamp meter remains absolutely unmoved (or rather with absolutely no perceptible motion) throughout these inequalities.

## A NEW SOURCE OF ELECTRICITY.

BY JOHN T. SPRAGUE.

A paper has been read recently to the Royal Society by Mr. J. A. Kendall, of Middlesbrough, describing a series of experiments as to a new method of generating electric currents, and as some of those experiments were performed some months ago in my laboratory by the inventor, when consulting me as to the originality of his idea, and some of the means for carrying it into effect, I may as well give some account of them.

It has been known for many years that many metals, which, at the ordinary temperature, are absolutely impervious to any gases, permit them to pass pretty freely at high temperatures; but it is not known how the transmission occurs, whether it is due to porosity resulting from expansion, or whether it is a kind of chemical action of the metal with its two sides in different atmospheres. The name "occlusion" is used for a temporary combination of gases with metals, which in the case of palladium and hydrogen appears to be an actual alloy, but little is known except the mere facts. Liquids also have, we know, a power of dissolving gases, and giving them up in such a manner that two gases separated by a liquid seal will gradually diffuse with each other.

Early in 1881 it occurred to Mr. Kendall that a heated platinum plate through which hydrogen was passing might act as an electrode. He attached tubes of platinum foil closed at the end to glass tubes, and placed these in a platinum crucible containing alkaline nitrates, phosphoric acid, and other salts in a state of fusion. On connecting a galvanometer to the tube and crucible no current was observed, but immediately that hydrogen gas was passed into the tube a deflection indicated the production of current.

Experiment also showed that if the inner tube contained air and the crucible was heated in a *reducing* flame a current in the reverse direction was produced.

Mr. Kendall's paper describes a long series of experiments with different saline substances and with different metals, resulting in the use of glass of some particular characters, and ultimately of porcelain and porous earthenware. It was found that the quantity of electricity produced was proportional to the area of the heated surface, and that the degree of temperature modifies the action, and must be adjusted to suit the materials used.

The experiments so far have been on a small scale to

Digitized by Google

examine principles, and Mr. Kendall has thus far found that hydrogen passes at about the rate of 0·7 cub. cent per minute (measured at ordinary temperature) per square inch at a nearly white heat, and that platinum with borate of lime gives E.M.F. = 0·36 of a Daniell, and with Berlin porcelain 0·7 of a Daniell. He has used a galvanometer which he graduated for his particular purposes by a voltameter, the indications of which represent

| | | | | | |
|---|---|---|---|---|---|
| 10° | deflection | = | 0·07 | cc. | hydrogen per minute. |
| 20 | „ | „ | 0·21 | „ | „ |
| 30 | „ | „ | 0·60 | „ | „ |
| 40 | „ | „ | 1·35 | „ | „ |

He further states that these deflections represent roughly the amount of hydrogen which must be supplied to the tube in order to produce those deflections. This statement, if confirmed, has great interest and importance, because it will show the molecular correspondences involved, and that the current is really related to the quantity of hydrogen, as it is to that of zinc in a battery, and that it is not simply a calorific action that is involved.

It is found that while the fused vitreous substances do not conduct electricity of low tension, yet they become conductors when hydrogen is present on one side and air or vacuum on the other. One experiment bearing on this is described by Mr. Kendall.

"A platinum tube 2¾in. long and ⅜in. diameter closed at one end was soldered to a strong iron tube and fixed vertically so as to be immersed 2¼in. in fused glass contained in a platinum cell 2¾in. deep and 1in. in diameter. The platinum tubes were connected to a galvanometer and the iron tube to a Sprengel pump. The cells were heated to bright redness in an oxidising flame and a good vacuum produced. Then, while no bubbles of hydrogen came down the fall tube of the pump, the galvanometer gave no deflection. The cell was then heated by a reducing flame, the galvanometer soon gave a steady deflection of 15deg., and bubbles of hydrogen came down the fall tube of the pump."

Experiments have been made towards producing a practical apparatus capable of working on a large scale, and producing electricity on a commercial scale. Whether merited success will attend Mr. Kendall's efforts remains yet to be seen, but there can be no doubt of the scientific interest of his researches.

Earlier experimenters have worked in a similar direction. Becquerel charged a condenser by means of a platinum wire in a heated glass tube which had another wire wound outside it; but he attributed the result to the transmission of electricity by this exterior wire from that dreadful delusion of the earlier electricians, the earth reservoir, through the agency of the differential temperatures. He probably was using a spirit flame with liberated hydrogen in it. Becquerel and others also obtained what they called "pyro-electric" currents; rods of iron and copper heated in a furnace gave no current, but when the copper was in glass heated to fusion a current was generated. The iron oxidises naturally, and it was considered that this was the origin of the electricity, and a galvanic cell was constituted of rods of iron and copper in a crucible of molten glass. But much as these experiments resemble those now described, and certain as it is that in the usual style of depreciating present workers by claiming their results for some earlier worker, or even dreamer, they will be considered as anticipating Mr. Kendall, yet they are absolutely distinct in principle. The essence of the present discovery is the presence of, and the part played by, free hydrogen.

It would appear that the electric current is related quantitatively to this hydrogen, which passes through the metals and intermediate substance on its way to combustion, attracted through the resistances by the differential state of the two atmospheres in which the electrodes stand. It is probable that the E.M.F. arises partly from capillary action in the metals, partly from the combustion of the hydrogen.

## CORRESPONDENCE.

### ZINC PRIMARY BATTERIES FOR ELECTRIC LIGHTING.

TO THE EDITOR OF THE ELECTRICIAN.

Sir: Mr. Desmond FitzGerald has contributed an article to *The Electrician* of Jan. 26 to which I must ask of your courtesy to be allowed to reply. Writing as he does with all the authority of a Gamaliel on a subject on which he probably has the support of the numerous body of scholars who have sat at his feet and learnt to regard his dogmas as indisputable, Mr. D. FitzGerald has greatly the advantage of me, who am but a practical man, extremely averse to, and with very little time at my disposal for paper controversies; but *magna est veritas, et prævalebit*, and, brushing aside all personalities as of no interest whatever to your readers, I will answer his points *seriatim*.

1. Mr. D. FitzGerald is impressed—perhaps also oppressed—by the belief that if it can be proved that the minimum consumption of zinc in a primary battery is at the invariable rate of 2·022lb. per horse-power per hour, then the impracticability of applying zinc carbon batteries to electric lighting will be indisputable. But even in that case his logic would be somewhat at fault, if it should be found that products of any value are recoverable from the electrolysis of the zinc; and in my battery, for example, 100lb. of zinc has been shown to have produced 167lb. of solid oxychloride of zinc.

2. The report of Mr. F. Ormiston from which he has quoted, showing the consumption of zinc with my battery to have been at the rate of 10·95oz. and 12·75oz. per horse-power per hour, was prepared not for myself, but for the Metropolitan Brush Electric Light and Power Company (to whom it is addressed), after exhaustive tests had been made by him during a fortnight at their central testing station in Milford-lane. Mr. Ormiston's ability and accuracy is very well known and could be vouched for by electricians of the highest authority; perhaps I may venture to name Mr. Latimer Clark, in whose service he was before he entered that of the Government. He is now absent from England, assisting to lay a cable in the Atlantic. The E.M.F. in action was not obtained from a single cell, as Mr. D. FitzGerald seems to suppose, and his inference as to the E.M.F. of the battery then under examination is therefore fallacious.

3. On Mr. FitzGerald's amiable suggestion that I am unaware of the elementary fact that water can only be decomposed when the current acting upon it is impelled by a minimum E.M.F. of close upon 1·49 volt, I will only remark that, if he intends his readers to understand that this must occasion a "back electromotive force" of 1·49 volt in each cell of a battery, such a view is as singular as it is original. When working, as in my battery, with an initial E.M.E. exceeding 100 volts and 50 amperes of current, this back electromotive force is overcome without very much influence on the meters, or on the "total (actual and potential) quantity of heat generated."

4. Mr. D. FitzGerald, coming to what he rightly says is practically the most important part of his article, traverses my assertion that the consumption of zinc per horse-power of energy is *not* a constant quantity, but a "varying amount according as it is influenced by one or other of several liquid electrolytes." In a paper on "Galvanic Batteries," written in 1882, and printed "for private circulation only," I pointed out that "experiments elaborately conducted since Faraday's 'Table of Electro-chemical Equivalents' was given to the world (1834) by such eminent investigators as Joule, Favre, and Silbermann, Andrews, Woods, Dulong, and others, which have definitely determined the heat of combination of metals with acids, must be considered to have conclusively demonstrated" . . .—to put the point succinctly—that the consumption of zinc in a primary battery cannot be correctly estimated from its so-called electro-chemical equivalent only, but that the amount consumed will vary when the zinc is acted upon by nitric, sulphuric, muriatic, or combinations of these acids. I might have added that the consumption will be influenced

Digitized by Google

by the nature of the electrolytes both in the carbon and in the zinc cell, and even have cited the authority of the illustrious Faraday himself in support of the further assertion that the total current is not produced by the sole action of the acids on the zinc.

In other words, I pointed out in the paper above referred to only one of several ways of accounting for a fact which many others besides myself have observed.

Mr. FitzGerald's calculations rest, on the contrary, upon the assumption that "the weight of zinc consumed in each cell of a battery per hour when current (1) is unity is (invariably) 18·9578 grains," which value is "derived from the fundamental . . . gram equivalent of zinc (32·75)." He arrives, therefore, at the same result as those who use the more familiar formula known to all electricians, viz.:

$$W = Z\,C\,t,$$

in which W is the weight in grams of the zinc,

Z the electro-chemical equivalent, or ·0003412,

C the strength of the current,

$t$ the time in seconds during which the current flows,

$$(z) \quad (c) \quad (t)$$

and $\cdot0003412 \times 746 \times 3600 = 916{\cdot}32672$ grams.

$= 2$lb. ·02 *of zinc per horse-power per hour.*

It would take too much of your space, sir, were I to attempt fully to disprove the accuracy of this formula, but I would beg to refer your readers to one or two indisputable authorities in support of my assertion that the theory on which it is founded is not less inaccurate than it is generally regarded as convenient for ordinary purposes, such as electro-plating, in which broad, practical results are more essential than mathematically accurate theories.

It was disproved in 1851 by Mr. Joule by experiments and observations of phenomena depending on the actual working electromotive forces of the battery.

Dr. Andrews disproved it in his papers in Vol. XXXII. of the *Phil. Mag.*, "On the Heat Disengaged during the Combination of Bodies with Oxygen and Chlorine," and in other subsequent papers.

Professor (now Sir William) Thomson disproved it in his paper "On the Application of Mechanical Effects to the Measurement of Electromotive Forces," in the *Phil. Trans.*, Vol. II., 1851. Observing that Mr. Joule's results gave a much higher thermal equivalent than could be accounted for on Faraday's theory, he showed that besides the heat evolved by the combination of zinc with oxygen, there must be additional heat generated, and therefore additional current produced by the further action of the acid on the zinc oxide.

Even Faraday himself, the originator in 1834 of the theory of electro-chemical equivalents, admitted its insufficiency six years later. In 1840 ("Exp. Res." 2,074) he wrote: "In a former series I have said that I do not think any part of the electricity of the voltaic pile is due to the combination of the oxide of zinc with the sulphuric acid. . . . But I now wish to say that the researches of Mr. Daniell on the nature of compound electrolytes ties together the electrolysation of a salt and the water in which it is dissolved in such a manner as to make it almost certain that, in the corresponding cases of the formation of a salt at the place of excitement in the voltaic circuit, a similar connection between the water and the salt formed must exist, and I have little doubt that the joint action of water, acids, and bases in Becquerel's battery [in which *no metal* is dissolved], in Daniell's electrolysations, and at the zinc in the ordinary active pile, are in principle closely connected together."

Finally and conclusively, Faraday ("Exp. Res.," 1137-40) made a series of experiments with the object of demonstrating the very fact that I have asserted, and which Mr. Desmond FitzGerald disbelieves. Using a battery composed of forty pairs of 3in. plates, he found that the amount of zinc consumed whilst producing a given amount of electric energy and decomposing a given volume of water in the voltameter *varied, according as it was influenced by one or other of several electrolytes*, as follows:—

| | | parts. | |
|---|---|---|---|
| With dilute sulphuric acid the zinc consumed was | | 186·4 | |
| „ Muriatic | „ ditto. | 152 | |
| „ Nitric | „ | 8 parts... 74·16<br>16 parts... 72·80<br>32 parts... 84·20 | Average 76·39 |
| „ Sulphuric | 9 parts + nitric 4 parts | 111·50 | |
| „ Sulphuric | 9 „ + nitric 8 „ | 90·40 | |
| „ Muriatic | 16 „ + nitric 6 „ | 84·40 | |

*Quod erat demonstrandum.*

Yours, &c.,
O. C. D. Ross,

## AMPERIAN HYPOTHESIS AND SECONDARY BATTERIES. ANSWERS.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: Mr. Snell will perhaps have the opportunity of gathering from some of my old writings that I came to the conclusion that "the polarity is reversed when the sign of the charge is reversed." I have not yet perused the explanations, to which he refers, given by Mr. H. Cunningham, but shall have an opportunity of doing so shortly.

The Wolverhampton Company are "too many" for me this week. Perhaps I may have something to say in regard to their letter on another occasion. They are doing good work on good business principles, and if they have not experienced ill results from the local action in a charged anode, which generally is of such detriment to the working of the battery and to the life of the element—well, I for one congratulate them on the fact. It is a great deal to be able to say that "gross overcharging" has failed to produce "any noticeable effect," even during twelve months, if we are to understand that the battery has been kept continuously working for that period.—Yours, &c.,

DESMOND G. FITZGERALD.

ERRATA.—In my article on "Zinc Batteries, &c.," page 250, line 19, a comma after the word "Still" alters the meaning; seven lines lower, "To that" should read "So that."

## RUNNING TWO DYNAMOS TOGETHER.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: I am sure all kindly disposed electricians will sympathise with "A Constant Reader" in his difficulty of harnessing two dynamos abreast who obstinately refuse to pull together, but seem to prefer, as your correspondent puts it, to work against each other, at the same time giving the engine plenty to do. There is, however, nothing abnormal in such behaviour, and "A Constant Reader" may derive some consolation from the consideration that the phenomenon he observed is explicable on strictly scientific principles. I do not venture to give the explanation here, for I think your space too valuable for descanting at length upon such elementary questions, but in order to help your correspondent out of his difficulty I will merely mention that not only the terminals of the two series machines, but also their brushes should be connected in parallel arc if he wishes to get their combined energy into the external circuit.—Yours &c.,

K—a.

## SIEMENS'S ARMATURE.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: I should esteem it a great favour if you or some of your valued correspondents would inform me if there is any advantage in the Siemens compound armature over the simple H form of armature for incandescence lamps; and, if so, how it is wound? A diagram would greatly oblige.—Yours, &c.

J. P. MUNRO.

### *ANSWERS TO CORRESPONDENTS.*

T. L. COCKS, JUN.—*You will find some particulars concerning the battery in our issue of the 22nd December last. We do not know where it is to be obtained.*

W. H. POTTER.—*You had better write Messrs. Siemens Brothers and Co., of 12, Queen Anne's-gate, S.W.*

### IMPORTANT NOTICE.

*** On and after the 8th inst. all communications should be addressed to our new premises, 1, Salisbury-court, Fleet-street, E.C., at which place *The Electrician* will, after next week's issue, be printed and published.

Several important letters, and the promised reprint of Mr. FitzGerald's paper, are postponed in consequence of our removal to fresh premises, and the introduction of entirely new type.

## THE POST OFFICE TELEGRAPHS AND THE NEW PATENTS ACT.

Not the least notable of the changes which have come into operation under the new Patents Act is that in the relations between patentees and Government departments. Previous to the 1st January of the present year the Crown might adopt for its own use the whole or any portion of an invention without paying for it, and complaints have occasionally been heard of valuable inventions being appropriated by Her Majesty's civil service without any compensation whatsoever reaching the proprietors. This can now no longer happen, the State having abandoned its right to invade or adopt any patented invention without paying an agreed price for it. With this abandonment, however, arises the necessity for compulsory right of usage. Formerly a patentee could retain the sale of his invention in his own hands against all comers except the Government. This exception being now abolished, it became necessary to abolish also the right of exclusive manufacture, and probably the much-discussed clause in the New Patents Act compelling the inventor to grant licenses for making the patented article arose out of the obvious necessity for protecting the State from the exorbitant charges of an inventor who might otherwise refuse to let anybody else make the article in order to sell it at a fancy price. The Government can demand the granting of a license, and it can make or use any invention at its pleasure, only it must pay for the privilege.

How far this new arrangement will prove acceptable to inventors whose chief relations are with Government departments we will not discuss at present, but it must materially affect these departments in relation to the servants employed by them, and in a way which it is perhaps worth considering just now. Under the old Act, a servant of the Crown had something to risk and nothing to gain by taking out a patent on his own account, for the Government department could have adopted it without acknowledgment, and censured the servant for patenting it. By the new Act, however, the Crown is put on a level with the general public, and thus an opening is afforded for patents to be taken out by its own servants. But there are sufficient reasons, both practical and moral, why this should not be permitted, and the Government appears to be quite alive to the fact. There is probably no department of the State more interested in the working of the Act than is that over which Mr. Fawcett presides, and it will be remembered that we published not long ago a notification issued by him prohibiting any servant of the Post Office taking out a patent without the permission of the head of his department. A similar notification has, we believe, been issued from the War Department. Now, the effect of this regulation on practice will, perhaps, be very slight indeed; but what we will call its moral effects may not be inconsiderable. For whereas the servant of the Crown and a private individual were formerly treated exactly alike—that is to say, rewarded or not at the pleasure of the Crown—the former is now treated exceptionally. The boon which the law has conferred on the inventing community generally is, in fact, withheld from servants of the Crown by a departmental order.

Inside such departments as the War Office, where inventions of great pecuniary value, and the Post Office, where inventions of great public utility are constantly introduced, the moral aspect of the question will present itself in this wise: The Crown has voluntarily chosen to figure in public as an ordinary buyer, but privately it declines to buy anything of its own servants, and thus places them now at a disadvantage as compared with inventors outside the Civil Service. Directly the Crown abandoned its claim upon all inventions for the Crown's use, it deprived itself of the legal right to the inventions of its own *employés;* and while admitting, as probably they all would admit, the inexpediency of their patenting inventions relating to their own department, they cannot fail to observe that, as the external value of their inventions has risen in the market, the intrinsic value of their services have risen proportionally. This fact will probably be borne in upon the departments themselves by the novel experience of having to pay expensively for outsiders' inventions, unless their own servants are sufficiently smart—and we may now add sufficiently disinterested—to forestall everybody else.

The commercial value of the services rendered by the exist-

Digitized by Google

ing technical branches of the departments we have named is almost incalculable; but to confine ourselves to that branch with which our readers are most interested, let us look at what has been done in electric telegraphy under the control of the State. The enormous extension of telegraph lines since their transfer to the Government is evidence of great labour and engineering skill; but the examination and testing of stores and apparatus for working these lines requires technical knowledge of a high order, without the command of which the Government would be at the mercy of the manufacturers. Besides this, a considerable proportion of the apparatus is made by the department itself, and the improvements introduced may be said to be of home growth. We infer this from the silence of non-official inventors. An exception must be made in respect to duplex and quadruplex working, for which we believe the department pays heavy royalties; but it is well known that both these systems, and especially the quadruplex, have been so remodelled that their telegraphic value has been almost doubled since they came into the hands of the department. In respect to the Wheatstone fast speed apparatus this is literally the fact, for whereas its fastest speed a few years ago was from 60 to 90 words a minute, and on cables much slower, it is now working uniformly at a speed of 200 words a minute, and a higher speed even than this is very often attainable. Of course something is due to improved construction of lines; but the exhibitions at Paris, Vienna, and the Crystal Palace showed plainly that the chief credit was due to improvements in the apparatus. Some altogether novel forms of signalling appliances were shown on those occasions, many of which, especially those comprised under the head of Relays, Repeaters, and Translators, excited the highest admiration among foreigners who understood their value, and provoked the remark that if the inventors had possessed patent rights their pecuniary reward would have been a very handsome sum. In galvanometers, too, and in electrical measuring instruments the Postal Telegraph Department appears somehow to have got the most exact and delicate appliances to be had anywhere. A few of them were recognisable as well-known forms, but improvements had converted them into something quite novel and better, whilst others were wholly new. Those devices, on the other hand, which are specially designed for combatting with a climate such as ours hardly receive their due recognition at foreign exhibitions; but they are in reality the triumph of the electricians of the British Post Office, and without them the nominal speeds of the higher class instruments would constantly fail. To maintain uniformity of working at the highest possible speed is an achievement to be proud of, and this from all trustworthy sources available to us is what the department's technical branch may lay claim to. That it also possesses the best form of batteries obtainable is only natural; but the method of employing them is peculiar to it, and results in the most economical system that could probably be devised. And economy in this relation means a huge saving for an undertaking of such magnitude as the English telegraphs.

To this array of successes we must add the telephonic systems in the several towns where telephony has been taken up by the Government. Notably in Newcastle it has perfected a system which in popularity, in efficiency, and we need hardly add in freedom from overhead wires, excels any system controlled by private enterprise. Not only are the general arrangements better, but the appliances are in every way simpler, more trustworthy, and more efficient, and the perfecting of these latter for the practical use of the public has, we believe, been entirely the work of the postal telegraph officers.

Now, the first thing that strikes us after a review of this kind in relation to the subject under discussion is the immense advantage reaped by the department having a staff of technical workers and advisers who are forbidden to make a market of their talents. Of course it will be said that they are paid for their talents, paid by the year. As we have no data on this point, we can only express a hope that the said talents are paid at their full valuation. But be this as it may, their public recognition is a matter which nobody will grudge, and after visiting the exhibitions we refer to we have often thought that those services were not as publicly recognised as they ought to be. When an officer in the army or navy invents or improves anything worth having the world hears of it; if an officer of the telegraphs does the like it would seem to be the fashion to regard it as part of his duty. At all events, we do not remember noticing any example of an opposite tendency. Whether that fashion will bear the strain of the new patent law remains to be seen. It seems to us that the law has materially altered the relations formerly obtaining between public servants and their employers, and that it would be wise to recognise the fact more frankly and generously for the future.

## SOME RELATIONS OF HEAT TO VOLTAIC AND THERMO-ELECTRIC ACTION OF METALS IN ELECTROLYTES.*

BY G. GORE, F.R.S., LL.D.

This research throws much light upon the real cause of the voltaic current. The author states that the object of it was "to ascertain the thermo-electric action of a series of metals in particular liquids, and to examine the relations of the thermo-electric to the chemico-electric behaviour of metals in electrolytes, and to ordinary chemical corrosion and the source of the voltaic current."

With this object, the thermo-electric tension series, also the chemico-electric tension series at 60° and 160°F., of thirteen metals, in solutions of twenty-two different salts, alkalies, and acids were experimentally found, and are shown in two tables. The same thermo and chemico-electric series were also determined in solutions of different strengths of the same substances, and are also exhibited in two tables; and the effects of difference of strength of liquid upon the orders of those series are inferred from the results.

Several other tables contain series of determinations of the electric potentials in volts, of numerous thermo-electric, and also of chemico-electric couples, of the same series of metals, in the weak solutions, and in the strong ones, and show the influence of strength of liquid upon thermo-electric and chemico-electric potential. The measurements of potential were made by means of a new form of thermo-electric pile (see *Proceedings* of the Birmingham Philosophical Society, Vol. IV., Part 1).

The influence of temperature upon the chemico-electric potential of those metals in the series of weak solutions, and also in the strong ones, at 60° and 160°F., was also determined, and the results are given in several tables.

The "voltaic reversal points," or temperatures, at which the two metals of a voltaic pair balanced each other and produced no current, in fifty-four different cases discovered during the research, were also determined, and are given. The metals and solutions employed were the same as those used in the previous series of experiments.

The potentials of voltaic current, with the same series of metals in the weak solutions at 60°F., were also determined in seventy-five instances, in each case in thermo-electric terms of one of the same metals in the same liquid; and the

* Abstract of a paper read before the Royal Society, Nov. 22, 1883.

Digitized by Google

numbers of degrees of difference of temperature of the particular thermo-electric couple to balance the corresponding voltaic couple, in each instance, are given in a table.

A series of experiments were also made to determine whether the difference of potential, caused by heating a voltaic couple, is completely accounted for by the electromotive forces produced by the same rise of temperature of the same metals separately in the same liquids, and the results are shown in a table.

With considerable difficulty, a series of about 120 determinations were also made of rates of ordinary chemical corrosion of the same metals in solutions of the same substances at 60°F., and a second series of about seventy-five determinations with the same metals and liquids at 160°F. were also made, and the results are given in two tables.

These and other results are contained in a series of twenty tables, and by comparing the contents of these various tables with each other, and also by means of additional experiments, a number of general conclusions were obtained. The following are the conclusions and the chief results arrived at by these means:—

It is shown that when metals in liquids are heated they are more frequently rendered positive than negative in the proportion of about 2·8 to 1·0; and that whilst the proportion in weak solutions was about 2·29 to 1·0, in strong ones it was about 3·27 to 1·0, and this accords with their thermo-electric behaviour as metals alone. The thermo-electric order of metals in liquids was, with nearly every solution, whether weak or strong, widely different from the thermo-electric order of the same metals alone. A conclusion previously arrived at was also confirmed, viz., that the liquids in which the hot metal was thermo-electro-positive in the largest proportion of cases were those containing highly electro-positive bases, such as the alkali metals. The thermo-electric effect of *gradually* heating a metal in a liquid was sometimes different from that of *suddenly* heating it, and was occasionally attended by a reversal of the current.

Degree of strength of liquid greatly affected the thermo-electric order of metals. Increase of strength, usually and considerably increased the potential of metals thermo-electro-negative in liquids, and somewhat decreased that of those positive in liquids.

The electric potential of metals thermo-electro-positive in weak liquids was usually about 3·87 times, and in strong ones 1·87 times, as great as of those which were negative. The potential of the strongest thermo-electric couple, viz., that of aluminium in weak solution of sodic diphosphate, was ·66 volt for 100°F. difference of temperature, or about one hundred times that of a bismuth and antimony couple.

Heating one of the metals, either the positive or negative, of a voltaic couple usually increased their electric difference, making most metals more positive, and some more negative; whilst heating the second one also, usually neutralised to a large extent the effect of heating the first one. The electrical effect of heating a voltaic couple is nearly wholly composed of the united effects of heating each of the two metals separately, but is not, however, exactly the same, because whilst in the former case the metals are dissimilar and heated to the same temperature, in the latter they are similar, but heated to different temperatures. Also when heating a voltaic pair the heat is applied to two metals, both of which are previously electro-polar by contact with each other as well as by contact with the liquid; but when heating one junction of a metal and liquid thermo-couple, the metal has not been previously rendered electro-polar by contact with a different one, and is therefore in a somewhat different state. When a voltaic combination in which the positive metal is thermo-negative and the negative one is thermo-positive is heated, the electric potential of the couple diminishes, notwithstanding that the internal resistance is decreased.

Magnesium in particular, also zinc and cadmium, were greatly depressed in electromotive force in electrolytes by elevation of temperature. Reversals of position of two metals of a voltaic couple in the tension series by rise of temperature were chiefly due to one of the two metals increasing in electromotive force faster than the other, and in many cases to one metal increasing and the other decreasing in electromotive force, but only in a few cases was it a result of simultaneous but unequal diminution of potential of the two metals. With eighteen different voltaic couples, by rise of temperature from 60° to 160°F., the electromotive force in twelve cases was increased, and in six decreased, and the average proportions of increase for the eighteen instances was ·10 volt for the 100°F. of elevation.

A great difference in chemical composition of the liquid was attended by a great change in the order of the volta-tension series; and the differences of such order in two similar liquids, such as solutions of hydric-chloride and potassic-chloride, were much greater than those produced in either of those liquids by a difference of 100° F. of temperature. Difference of strength of solution, like difference of composition or of temperature, altered the order of such series with nearly every liquid; and the amount of such alteration by an increase of four or five times in the strength of the liquid was rather less than that caused by a difference of 100° F. of temperature. Whilst also a variation of strength of liquid caused only a moderate amount of change of order in the volta-tension series, it produced more than three times that amount of change in the thermo-electric tension series. The usual effect of increasing the strength of the liquid upon the volta-electromotive force was to considerably increase it, but its effect upon the thermo-electromotive force was to largely decrease it. The degree of potential of a metal and liquid thermo-couple was not always exactly the same at the same temperature during a rise as during a fall of temperature. This is analogous to the variations of melting and fusing-points of bodies under such conditions, and also to that of super-saturation of a liquid by a salt, and is probably due to some hindrance to change of molecular movement.

The rate of ordinary chemical corrosion of each metal varied in every different liquid; in each solution also it differed with every different metal. The most chemically positive metals were usually the most quickly corroded, and the corrosion of each metal was usually the fastest with the most acid solutions. The rate of corrosion at any given temperature was dependent both upon the nature of the metal and upon that of the liquid, and was limited by the most feebly active of the two, usually the electrolyte. The order of rate of corrosion of metals also differed in every different liquid. The more dissimilar the chemical characters of two liquids, the more diverse usually was the order of rapidity of corrosion of a series of metals in them. The order of rate of simple corrosion in any of the liquids examined differed from that of chemico-electro, and still more from that of thermo-electromotive force. Corrosion is not the cause of pure thermo-electric action of metals in liquids.

Out of fifty-eight cases of rise of temperature, the rate of ordinary corrosion was increased in every instance except one, and that was only a feeble exception; the increase of corrosion from 60° to 160° F. with different metals was extremely variable, and was from 1·5 to 321·6 times. Whether a metal increased or decreased in thermo-electro or chemico-electromotive force by being heated, it increased in rapidity of corrosion. The proportions in which the most corroded metal was also the most thermo-electro-positive one, was 65·57 per cent. in liquids at 60° F., and 69·12 in the same liquids at 160° F.; and the proportion in which it was the most chemico-electro-positive at 60° F. was 84·44 per cent., and at 160° F. 80·77 per cent. The proportion of cases, therefore, in which the most chemico-electro-negative metal was the most corroded one increased from 15·56 to 19·23 per cent. by a rise of temperature of 100° F. Comparison of these proportions shows that corrosion usually influenced in a greater degree chemico-electric than thermo-electric actions of metals in liquids. Not only was the relative number of cases in which the volta-negative metal was the most corroded increased by rise of temperature, but also the average relative loss by corrosion of the negative to that of the positive one was increased from 3·11 to 6·32.

The theory most consistent with all the various results and conclusions is a kinetic one:—That metals and electrolytes are throughout their masses in a state of molecular vibra-

Digitized by Google

tion. That the molecules of these substances, being frictionless bodies in a frictionless medium, and their motion not being dissipated by conduction or radiation, continue incessantly in motion until some cause arises to prevent them. That each metal (or electrolyte) when unequally heated, has to a certain extent, an unlike class of motions in its differently heated parts, and behaves in those parts somewhat like two metals (or electrolytes), and those unlike motions are enabled through the intermediate conducting portion of the substance to render those parts electro-polar. That every different metal and electrolyte has a different class of motions, and in consequence of this, they also, by contact alone with each other at the same temperature, become electro-polar. The molecular motion of each different substance also increases at a different rate by rise of temperature.

This theory is equally in agreement with the chemico-electric results. In accordance with it, when in the case of a metal and an electrolyte the two classes of motions are sufficiently unlike, chemical corrosion of the metal by the liquid takes place, and the voltaic current, originated by inherent molecular motion under the condition of contact, is maintained by the portions of motion lost by the metal and liquid during the act of uniting together. Corrosion, therefore, is an effect of molecular motion, and is one of the modes by which that motion is converted into electric current.

In accordance with this theory, if we take a thermo-electric pair, consisting of a non-corrodible metal and an electrolyte (the two being already electro-polar by mutual contact), and heat one of their points of contact, the molecular motions of the heated end of each substance at the junction are altered, and as thermo-electric energy in such combinations usually increases by rise of temperature, the metal and liquid, each singly, usually becomes more electro-polar. In such a case the unequally heated metal behaves to some extent like two metals, and the unequally heated liquid, like two liquids, and so the thermo-electric pair is like a feeble chemico-electric one of two metals in two liquids, but without corrosion of either metal. If the metal and liquid are each when alone thermo-electro-positive, and if when in contact the metal increases in positive condition faster than the liquid by being heated, the latter appears thermo-electro-negative, but if less rapidly than the liquid, the metal appears thermo-electro-negative.

As, also, the proportion of instances is small in which metals that are positive in the ordinary thermo-electric series of metals only become negative in the metal and liquid ones (viz., only 73 out of 286 in weak solutions, and 48 out of the same number in strong ones), we may conclude that the metals, more frequently than the liquids, have the greatest thermo-electric influence; and also that the relative largeness of the number of instances of thermo-electric-positive metals in the series of metals and liquids, as in the series of metals only, is partly a consequence of the circumstance that rise of temperature usually makes substances, metals in particular, electro-positive. These statements are also consistent with the view that the elementary substances lose a portion of their molecular activity when they unite to form acids or salts, and that electrolytes, therefore, have usually a less degree of molecular motion than the metals of which they are partly composed.

The current from a thermo-couple of metal and liquid, therefore, may be viewed as the united result of difference of molecular motion, first of the two junctions, and second, of the two heated (or cooled) substances; and in all cases, both of thermo and chemico-electric action, the immediate true cause of the current is the original molecular vibrations of the substances, whilst contact is only a static permitting condition. Also that whilst in the case of thermo-electric action the sustaining cause is molecular motion supplied by an external source of heat, in the case of chemico-electric action it is the motion lost by the metal and liquid when chemically uniting together. The direction of the current in thermo-electric cases appears to depend upon which of the two substances composing a junction increases in molecular activity the faster by rise of temperature, or decreases the more rapidly by cooling.

In a separate paper on "Some Relations of Chemical Corrosion to Voltaic Currents" the author has investigated the amounts of external voltaic current produced by the corrosion of known weights of various metals at atmospheric temperature.

---

## THE PHYSICAL THEORY OF THE GRAMME MACHINE.

BY DESMOND G. FITZ-GERALD.

The theory of the action of the Gramme machine put forward by "E," in your last issue, may be accepted as a very neat and concise illustration of a mode of explaining magneto-electric phenomena which I regard as artificial, if not fanciful, and as being likely to lead into error. The communication of "E" contrasts favourably with that of "Tubanticus" (p. 233), who is also an advocate of this method, and who, in my view, puzzles himself and others quite unnecessarily. I observe with satisfaction that neither of your correspondents uses the expression "cutting the lines of magnetic force," which, I must confess, is not a favourite one with me. The important point, however, is that your readers have now an opportunity of comparing two explanations of the *modus agendi* of a class of dynamo machines in very extensive use; both of which explanations are, I think, definite and intelligible—although "E" ungraciously refers to my own as being "involved and lengthy."*

In judging of the value of a theory, we have to consider not only whether it is reconcilable with known facts—which, of course, is a *sine quâ non*—but also whether it is capable of suggesting other facts which are not known or have been overlooked, whether its tendency is to establish a broad generalisation rather than an isolated and particular explanation, and last (but to my mind not least) whether, in physics, it be physically true.

Taking these considerations in inverse order, I object to the "lines of force" explanation, because the pretty phenomena which suggest their existence are in my view merely a consequence of the attraction between currents in the same direction, which is a demonstrated fact. A minute particle of iron is thrown upon a plane surface in proximity to a magnet. It instantly becomes a magnet by induction, *i.e.*, becomes analogous to the inducing magnet, which itself is analogous to a solenoid traversed by a current. A condition not previously existent is established, and the minute magnet, if free to move, places itself in the direction of the resultant of the attractive forces which may be predicated from the analogy just mentioned. Any number of small magnetic particles, in the form of iron filings, similarly become magnets by induction, and similarly verify the analogy. The lines of force exhibited by means of them have no greater claim to be considered as physically existent apart from current attraction than has fire or flame apart from combustion and heat. In a sense which will be understood from what precedes, they are purely imaginary. No doubt they are highly suggestive to the mathematician, and offer great temptations to the ingenious theorist. In physics, however, it is safest to seek the most direct links in the chain of cause and effect. When we have learned that electric currents attract or repel each other according to their relative direction, that the distinction between an ordinary magnet and an electro-magnet is more apparent than real, and that the law of Lenz, so far as we have gone, admits of no exception, it is dangerous to traverse the thin ice of fresh hypothesis when we can progress upon firm grounds of theory. *Quod nunc est demonstrandum.*

If we inquire *why* the cutting of lines of force by a conductor, or their passage through a coil, should produce a current, the only answer we can obtain is a statement of the observed fact; the latter is not referred to a category; no generalisation is established. This, be it observed, is a characteristic of barren hypothesis. And if we ask why the current is sometimes in one direction and sometimes in the other,

* My explanation (p. 179) is really included in twenty-nine lines, commencing at "Taking a section," and ending at "collector marked +." The remainder of the communication is educational—referring to facts which are known, and should be more generally known. It could not advantageously have been omitted.

Digitized by Google

the answer is merely an extension of the hypothesis; we must distinguish between "north lines of force" and "south lines of force"—defined as "lines coming from a north pole" and "lines coming from a south pole"—as though there were two sets of lines, coming in each case from one pole alone. And if we take the final conclusion from the hypothesis, viz., that "the addition to a coil of lines of force coming from a north pole" causes a current to flow in one direction, whilst the addition of lines coming from a south pole produces a current in the contrary direction, experiment at once flatly negatives this conclusion. But here I anticipate a consideration which should come last according to the order I have adopted.

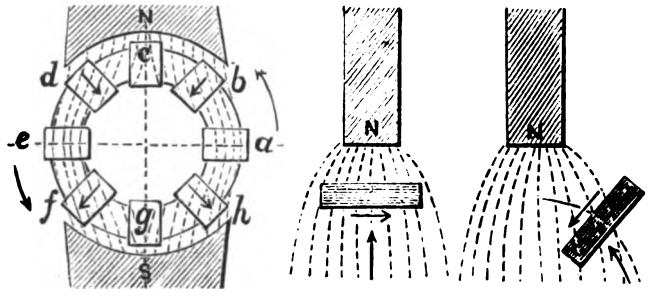

Fig. 1.—"E's" Diagram.

The diagram (Fig. 1) given by "E," and his hypothesis, prove too much. I will ask the editor kindly to reproduce the former for our further consideration. What a perfect machine it implies—almost suggesting the suspicion that the theory is made to fit the machine, even though the machine should not quite fit the theory!

We are spared any mention of the "cutting of lines of force" at N and at S by the coils C and G; and so, if any investigator, taking the trouble to connect one of these coils with a galvanometer whilst the ring is rotating, should observe that it behaves abnormally when in proximity to the poles, the perturbations must be due to some "cussedness" in the coil; certainly it is no fault of the theory! If we take

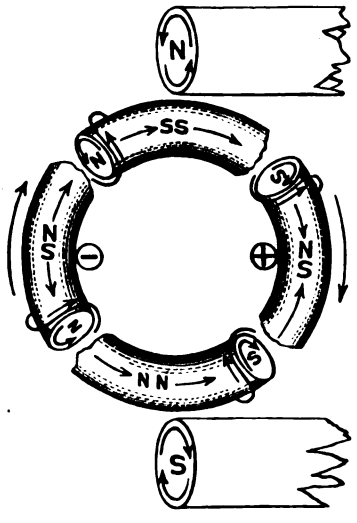

Fig. 2.—Mr. FitzGerald's Diagram.

away the soft iron and substitute for it a ring of wood, how beautifully the machine would still work—for we all know that the lines of force will freely traverse wood! No possible inversion of the direction of the current, no necessity for a commutator, nor for anything beyond the simple Gramme "collector," to exhibit all the inductive effects even when the soft iron has been removed; therefore no possible waste of energy in the machine as ordinarily made. It is refreshing to observe such perfect accord—accidental too—between theory and practice!

Let us now turn to my diagram (Fig. 2). Doubtless some if not many, must have observed that it does not exhibit the Gramme machine in quite so perfect a light, that it suggests remediable imperfections in all machines upon this type. By the law of Lenz, the coils as they approach the external poles N and S must be traversed by an inverse current, and as they recede from these poles they must be traversed by a direct current. These currents are wholly distinct from that generated by the reaction upon the coils of the varying magnetism of the armature. One of them necessarily must be in the same direction as the effective current; the other must be opposed to it. So long as the latter is not eliminated there is at least one remediable imperfection in the Gramme machine. The two currents, it is true, exactly neutralise each other; but their production necessitates an expenditure of energy in waste. Am I sure that they actually exist—that they are not the creations of a defective theory? It will not do to be mistaken on such a point, especially when a low resistance reflecting galvanometer, a magnet, and insulated wire are at my elbow. I wind upon a wooden reel a coil of of wire C, attach its terminals to the galvanometer G (which in reality is as far from N as the width of the room will admit), and I move C suddenly, in the direction of the arrow, into the position indicated by the dotted line. I observe a "throw" of the galvanometer needle to the *left*. I then suddenly continue the motion in the direction indicated by the curved arrow, and I observe a second deflection, this time to the *right*. (See Fig. 3.)

It is evident, therefore, that there exists in machines of the Gramme type an inductive effect which is detrimental because it is not understood, but which may be utilised or eliminated when the theory of these machines is better under-

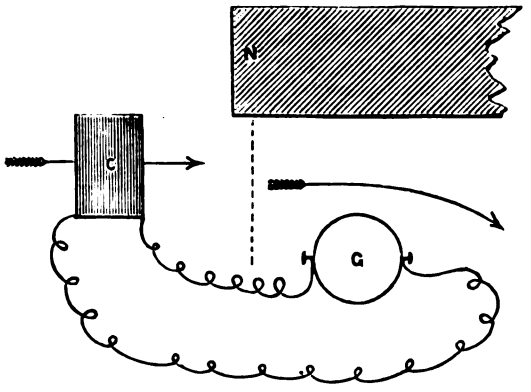

Fig. 3.

stood. No indication of this unknown or overlooked fact is afforded by the diagram of "E." According to my diagram, if we substitute for the armature of soft iron a ring of wood, the action to which the effective current generated in the machine is at present wholly due vanishes with the "amperian currents," leaving only the inverse and direct currents produced by the passage of the coils by the poles of the field magnet, which current might be rendered evident and effective by means of a commutator. If these consequences be true, they characterise the theory as one fertile in truth, and constitute the strongest evidence in its favour. Other considerations of even greater interest are suggested by the diagram in question and the theory which it elucidates. If, in the construction of the machine, the object be to convert the ring-armature virtually into two horse-shoe magnets having their similar poles in contact on a given diameter of the ring, is it not possible to obtain this result directly instead of indirectly? Instead of winding a great length of wire round an inducing magnet, could we not more effectively utilise a shorter length in the form of coils enveloping certain portions of the ring, already furnished with what may be considered as a secondary coil? I will not at the present moment attempt to offer a solution of this and of other questions related to it; it is sufficient to point out that they are suggested by the theory.

We now come to what I have reserved as the last criterion of the value of the theory advanced by "E," whose communication derives its importance mainly from the fact that it expresses the views of a number of authorities, some of

Digitized by Google

whom have very great pretensions to electrical knowledge. Is this theory in accord with the results of experimental observation? Is it a fact that "adding north lines of force" to a coil of wire produces a current in one direction, and that causing the coil to enclose "south lines of force" produces a current in the opposite direction? If it be so, I may at once admit that the explanation of the action of the Gramme machine which I have derived from the theory of Ampère and the law of Lenz falls to the ground, since it involves the principle that "*so long as the direction of the amperian currents remains the same, the direction of the induced current* (inverse) *remains the same, whether the north or the south pole of a magnet be introduced within a coil; and the direction of the induced current* (direct) *remains the same, whether a north or a south pole be withdrawn from a coil.*" The *experimentum crucis* is therefore extremely simple—so elementary, in fact, that I should be inclined to apologise for apparently making a great point of it, were it not that many individuals, and even some books of authority in electrical matters, deny its results with the calm confidence that can proceed only from absolute ignorance of them.

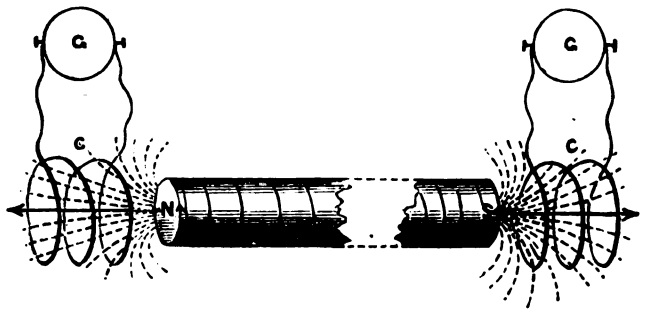

Fig. 4.

Let C (Fig. 4) represent a coil of wire, of which the terminals are connected to a galvanometer, G, placed at a considerable distance from it. I insert within the coil the north-seeking pole N of a magnet, and I observe a "throw" of the galvanometer needle in a certain direction, say to the *right*. Now if, without reversing the direction of the magnet, I insert its south-seeking pole within the same coil (as shown at the right-hand portion of the figure) what will be the direction of the "throw" produced in this case? According to the theory put forward by "E," it would be to the *left*, indicating a current in the reverse direction to that generated in the former case, since "south lines of force" instead of "north lines of force" are now being "added" to the coil. As a matter of fact, however, the deflection will again be to the *right*.

## ON THE PHYSICAL CONDITION OF IRON AND STEEL.*

BY PROFESSOR D. E. HUGHES, F.R.S.

(CONCLUDED FROM PAGE 251.)

*Influence of Annealing upon the Molecular Structure of Iron and Steel.*

The magnetic balance shows that annealing not only produces softness in iron, and consequent molecular freedom, but it entirely frees it from all strains previously introduced by drawing or hammering. Thus a bar of iron drawn or hammered has a peculiar structure, say a fibrous one, which gives a greater mechanical strength in one direction than another. This bar, if thoroughly annealed at high temperatures, becomes homogeneous in all directions, and has no longer even traces of its previous strains, provided that there has been no actual mechanical separation into a distinct series of fibres.

From Table I. we see that a regular increase of softness occurs as the temperature at which Swedish iron is annealed increases, the maximum being at a point under that of fusion.

Experiments regarding the time required for perfect annealing showed that whilst hard steel required several hours, soft iron might be cooled in a few minutes without losing its degree of softness; consequently, knowing the great value of high temperature, the author adopted the following method. The tube was heated to a white heat or otherwise, the iron wires to be annealed were introduced quickly, and the instant they had the same temperature they were withdrawn, and simply allowed to cool in the air. The wire employed being 1 millimetre diameter, the whole operation was complete in two minutes. This is not suggested as the best practical method of annealing, although in the case of these wires it produced the best result; but the experiments show that, whatever method is employed, the heating should be as rapid as possible to a high degree of temperature, and that the wire should cool in a completely neutral medium or atmosphere.

Table I.

*Influence of Annealing upon Swedish Iron, Sample G.*

| | Approximate Temperature. | | Degrees of softness indicated upon the Magnetic Balance. |
|---|---|---|---|
| | Cent. deg. | Fahr. deg. | Deg. |
| Wire hard drawn as furnished by makers ..... | — | — | 230 |
| Annealed at black heat... | 500 | 950 | 255 |
| „ dull red..... | 700 | 1300 | 329 |
| „ bright red ..... | 1000 | 1800 | 438 |
| „ „ yellow..... | 1100 | 2000 | 507 |
| „ „ yellow-white | 1300 | 2300 | 525 |

The facts regarding annealing, as pointed out by the measurement of the magnetic capacity of iron wires, have no doubt been in a great measure perceived by ordinary mechanical methods. The results of the author's researches may be thus formulated:—

1. The highest degree of softness in any variety of iron or steel is that obtained by a rapid heating to the highest temperature less than fusion, followed by cooling in a medium incapable of changing its chemical composition.

2. The time required for gradual cooling varies directly as the amount of carbon in alloy.

Thus in absolutely pure iron rapid cooling, as in tempering, would not harden it, whilst steel might require several hours or days, even for pieces only one millimetre diameter. Slow cooling has no injurious effect upon iron, when cooled in a neutral field; consequently, where time is no object, we may employ slow cooling in every case.

A wire or piece of iron thoroughly annealed must not be bent, stretched, hammered, or filed; the hardening effect of a bend is most remarkable, and the mere cleaning of the surface by sand-paper hardens that surface by several degrees on the scale.

The following table shows the effect of annealing upon a series of wires, kindly furnished expressly for these experiments by Messrs. Frederick Smith and Co., of Halifax.

Table II.

| Mark. | Description. | Magnetic Capacity. | |
|---|---|---|---|
| | | Bright as sent. | Annealed. |
| | | Degrees on Scale. | Degrees on Scale. |
| G | Best Swedish charcoal iron, 1st variety ..... | 230 | 525 |
| F | Best Swedish charcoal iron, 2nd variety ..... | 236 | 510 |
| T | Best Swedish charcoal iron, 3rd variety ..... | 275 | 503 |
| S | Swedish Siemens-Martin iron | 165 | 430 |
| H | Puddled iron, best best..... | 212 | 340 |
| Y' | Bessemer steel, soft ..... | 150 | 291 |
| Y | Bessemer steel, hard ..... | 115 | 172 |
| Z | Crucible fine cast steel ..... | 50 | 84 |

From the above table it will be seen that annealing had a

* Paper read before the Institution of Mechanical Engineers.

Digitized by Google

great effect on the iron wires, doubling their value, and that Swedish iron stands far in advance of puddled iron; consequently, for the cores of electro-magnets in telegraph instruments—as, in fact, for all electro-magnets—Swedish iron is the most suitable, and the magnetic balance may find a field of practical utility in measuring each core before it is used in an electro-magnet, and may also aid us by its measurements in finding the best methods of annealing.

*Tempering.*

The influence of tempering upon the magnetic retentivity, or molecular rigidity, has been shown in every piece of iron or steel yet examined. Swedish iron hardens but 10 to 20 per cent. by tempering, whilst cast steel hardens 300 per cent.;* the molecular rigidity of tempered steel being 18 times greater than that of soft iron. The influence of different methods of tempering on crucible steel is shown in Table III., ranging from its ultimate molecular rigidity to its ultimate softness when annealed.

TABLE III.

| Crucible Fine Cast Steel Tempered. | Mark. | Magnetic Capacity. |
|---|---|---|
| Bright yellow heat, cooled completely in cold water | A | 28 |
| Yellow red ditto | B | 32 |
| Bright yellow, let down in cold water to straw colour | C | 33 |
| Ditto blue | D | 43 |
| Bright yellow, cooled completely in oil | E | 51 |
| Bright yellow, let down in water to white | F | 58 |
| Red heat, cooled completely in water | G | 66 |
| Ditto in oil | H | 72 |
| Annealed | J | 84 |

We may from this represent graphically a diagram which includes all methods of tempering; and another diagram which shall include all varieties of iron, from the softest iron to the hardest steel, intermediate qualities of hard iron and mild steel finding their place between the two extremes.

The numerous specimens of wires tested have been forwarded direct from the manufacturers, at the request of the author's friend, Mr. W. H. Preece, F.R.S., Electrician to the General Post Office. The chemical analyses of most of these wires have not been furnished; but Messrs. Frederick Smith and Co., of Halifax, not only supplied a beautiful series of wires, but had them specially analysed by Mr. Henry S. Bell, of Sheffield, in order that the results should be as exact as it was in their power to make them. The author therefore neglects in this paper all other samples except those of Messrs. Frederick Smith and Co.; they all stand between or are included by the two extremes, of Swedish iron and cast steel.†

Table IV. gives the complete results of the mechanical, chemical, and physical tests upon these wires. The tensile strength and electric conductivity are as furnished by Messrs. Frederick Smith and Co., the chemical analyses are as given by Mr. Henry S. Bell, and the magnetic capacities of the bright hard drawn wires, as of the annealed and tempered wires, were determined by the author with the aid of the magnetic balance.

Table IV. will aid us in drawing several conclusions. Taken in conjunction with Table III., it shows—

1st. That the degree of temper in cast steel is dependent jointly on the heat to which it is raised and the degree by which this is lowered in rapid cooling; the extremes in Table III. giving the relative molecular rigidity of the softest and hardest steel.

2nd. That a peculiar mild and homogeneous temper is obtained in oil.*

3rd. That the tempers or degrees of hardness, when steel is let down through the various colours, vary with the kind of steel tempered, as well as with the heat from which it has been let down.

In these experiments the author has noticed that the highest degree of temper has not been obtained with wires containing the relatively highest proportion of carbon. The maximum thus far was obtained with but 0·62 carbon; whilst in a series of steel wires, made expressly for these experiments, but in which the manufacturer stated only the amount of carbon, the results were as in Table V.

TABLE V.

| | Mark. | Magnetic Capacity. | | Carbon. |
|---|---|---|---|---|
| | | Annealed. | Tempered. | |
| | | Degrees. | Degrees. | Per cent. |
| Bessemer soft steel | Y′ | 291 | 255 | 0·15 |
| Steel made for these Experiments | S′ | 348 | 206 | 0·40 |
| Steel made for these Experiments | $S^2$ | 250 | 160 | 0·55 |
| Steel made for these Experiments | $S^3$ | 209 | 133 | 0·60 |
| Steel made for these Experiments | $S^5$ | 195 | 107 | 0·75 |
| Steel made for these Experiments | $S^4$ | 144 | 61 | 0·65 |
| Bessemer hard steel | Y | 172 | 60 | 0·44 |
| Fine crucible cast steel | Z | 84 | 28 | 0·62 |

It will be seen that the hardness as indicated in column "tempered" is not directly as the proportion of carbon; a marked example being the wire with 0·75 carbon, which is far softer than that with 0·62. The author might here have doubted the truth of the magnetic balance, if he had not previously verified its results by mechanical tests. In order, however, to test the accuracy of the results, the wires $S^5$ and Z were bound together, heated together to the same temperature, and plunged together in cold water. This was repeated several times, with the invariable result that the wire Z with 0·62 carbon was glass-hard and could not be marked by a file, whilst the wire $S^5$ with 0·75 carbon could be easily cut by the same file. Again, we notice that in Table IV. the wires T, called soft Swedish iron, contain the same amount of carbon (0·15) as that marked Y′ in Table V. called Bessemer soft steel; but that whilst Y′ is comparatively hard when tempered, it does not become greatly softened by annealing. This is due probably to its greater proportion of some other ingredients. Similarly the wire S is much softer than H in Table IV., both having a similar amount (0·10) of carbon. The hardness of H when annealed is probably due to its greater proportion of phosphorus or some other substance.

It may be too soon to try and correlate the physical changes occurring in tempering with the corresponding chemical analyses; but the author believes that he has shown reason to hope that we may eventually obtain, by uniting chemical with physical analysis, a more clear insight into the mysteries of iron and steel.

*Dividing line between Iron and Steel.*

Mechanical tests, as well as chemical analyses, have failed to find any distinct line of separation between the numerous

* For instance, in Table IV. below, the figure for Swedish iron No. 7 annealed is 525, tempered hard 425. On the other hand, the figure for cast steel annealed is 84, tempered hard 28. The reciprocals of these figures give what may be called a scale of hardness.

† The author does not desire that Swedish iron should be considered as the softest of all possible irons, or tempered cast steel as the final limit of hardness. They are simply the limits found during these researches, but they may possibly be widened by a more extended series of irons and steels.

* The author has found, by a method more complicated than here described, and by the use of the induction balance, that all tempers heretofore tried (excepting those in oil) give a steel not homogeneous; and a temper let down to straw or blue has external strains differing from those of the interior.

varieties of iron and steel. The physical method which the author has employed shows clearly that there is no dividing line between iron and steel. If we glance at Fig. 3 we see that we have a continuous series from the softest iron to the hardest steel, and between them we have every variety of intermediate quality. In point of fact the sixty brands which have been tested fill up all the gaps; and by their means we could choose irons gradually hardening into steel, or steel gradually softening into iron. Thus ordinary iron is physically a soft steel, and steel a hard iron. All are hardened by temper; all are hardened by mechanical treatment, as hammering and rolling; all are hardened by strains and stresses of any nature whatever; the difference, though large, is only in degree. At the extreme end towards iron, mechanical hardening has a greater effect than tempering. At the steel end, tempering has a greater effect than mechanical hardening. We might here suppose we could find a physical dividing line; but the author has found some mild steels to stand just on that dividing line, which had previously appeared the most satisfactory. We are thus forced to adopt an arbitrary line.

*Relations of Physical Forces in Iron and Steel.*

Leaving aside all theoretical considerations and hoped for improvements in the methods of observation, the author believes that he has demonstrated clearly that, by the aid of the instrument and methods described, we can at once determine the physical state of iron, as influenced by tempering and mechanical hardening, from the ultimate degree of softness to that of hardness; that we can at once determine the best iron for electro-magnets, and the best methods of softening it, as well as the best steel for permanent magnets, and the best temper to be given to it. He therefore ventures to hope that the magnetic balance will prove an aid of no small value in all researches into the physical state of iron and steel.

## THE DIRECT UNITED STATES CABLE COMPANY (LIMITED).

Report of the directors for the six months ending 31st December, 1883, to be presented at the thirteenth ordinary general meeting of the Company, to be held at the Cannon-street Hotel, Cannon-street, in the city of London, on Friday, the 8th day of February, 1884, at two p.m. The usual statements of account for the half year ending 31st December, 1883, are submitted herewith. For the half year the revenue, after deducting out-payments, amounted to £73,472 12s. 7d., against £77,469 8s. 3d. (after similar deductions) for the corresponding half year of 1882, being a difference of £3,996 15s. 8d. against the half year under review. The working and other expenses, including interest on debentures and income-tax, &c., amounted to £21,824 4s. 5d., leaving a balance of £51,648 8s. 2d. as the net profit of the half year, making, with £1,852 7s. 11d. brought forward from the previous half year, a total balance of £53,500 16s. 1d. For the corresponding half year of 1882 the working expenses and other payments amounted to £22,786 3s. 2d. Interim dividends of 1½ per cent. each for the quarter ending 30th September, 1883, paid 16th November, 1883, and for quarter ending 31st December, 1883, payable 16th February, 1884, together amounting to £30,355, have been declared. The sum of £19,621 7s. 7d. has been set aside to the reserve fund (thereby increasing that fund to £340,000), leaving a balance of £3,524 8s. 6d., which has been carried forward. An interruption has occurred in our short section of cable, which, however, does not affect the receipts as the traffic passes by the alternative land line between Torbay and New York. The repair will be effected as soon as possible. Shareholders who are unable to attend the meeting are requested to sign and return the enclosed form of proxy, which to be of use should be lodged at the Company's office before two o'clock p.m. on the 6th February next.

## SUBMARINE TELEGRAPH COMPANY.

Report of the directors to be submitted at the meeting of the proprietors to be held at the offices of the Company, 2, Throgmorton-avenue, London-wall, E.C., on Thursday, the 7th day of February, 1884, at one o'clock p.m.

The accounts for the six months ending 31st December, 1883, show a balance of profit of £35,799 7s. 5d. in favour of this Company, which enables the directors, after adding the sum of £8,111 2s. 6d., being 15 per cent. of the gross receipts, to the reserve fund, to recommend a dividend at the rate of 15½ per cent. per annum, and to carry over a balance of £176 1s. 9d. In comparing these accounts with those for the corresponding period of 1882, it will be found that, although the gross receipts have fallen £5,166 13s. 9d., the net receipts are only reduced by £2,465 19s. 1d., in consequence of the reduction of the working expenses. The falling off in the receipts is partly due to a diminution in the number of messages transmitted, and partly to the shorter length of the messages; and the reduction in the expenses arises chiefly from the item of repairs to cables, which have cost in the six months £2,516 9s. 8d., against £4,417 9s. 6d. in the six months ending 31st December, 1882. During the half year there has been but one breakage in the cables between England and France, which was very speedily repaired; on the other hand, the two cables to Holland, belonging to the Government, have unfortunately been interrupted since November, and the engineer has not yet been able to repair them. This is partly owing to the weather and the fishing operations in the North Sea, which interfere with this work, but chiefly to the very weak condition of the cables. Arrangements have been made with two French newspapers, the *Paris Morning News* and *Galignani's Messenger*, for letting to each of them the use of a wire between London and Paris during the night on the usual newspaper terms. The directors regret to report the death of Mr. George Copeland Capper, the first auditor of the Company. As by the deed of settlement only two auditors are required, they recommend that the vacancy be not filled up.

Digitized by Google

## THE EASTERN TELEGRAPH COMPANY (LIMITED).

The twenty-third half-yearly ordinary general meeting of this Company was held at the City Terminus Hotel, Cannon-street, London, on Thursday, January 24th, 1884, under the presidency of John Pender, Esq., M.P.

The notice convening the meeting, and the minutes of the last meeting having been read and confirmed, and the report having been taken as read,

The CHAIRMAN said: Before putting the resolution to the meeting for the adoption of the report I shall make, as usual, a few remarks upon the business of the past six months. Our revenue for the six months ended September 30th, 1883, amounted to £283,070, against in the corresponding period of last year £341,151; being a decrease of £58,081, arising mainly from the changed circumstances in Egypt. At the time we earned the larger amount the war was going on and the press correspondents were very active. The consequence was that the revenue was very considerable. At the corresponding period of last year we paid a dividend and bonus equal to 6 per cent. on our ordinary capital and carried forward a balance of £56.836. At that time we increased the dividend by about a half per cent. This time we pay the same dividend and bonus and carry forward to the present half year £13,679. We are also paying interest on additional capital. I am, however, happy to say that our current revenue is satisfactory, so that at the end of the financial year we hope (we see our way indeed) to pay the same dividend as we are paying to-day. The chief decrease in our revenue is in the traffic with Egypt, but the shareholders will observe that there has been a serious falling off in our receipts from the Black Sea Company. I may mention that the Black Sea cable is one that will always be more or less influenced by peace or war. There is a steady traffic there, but if anything takes place we generally find that the Black Sea cable participates very conside in increased traffic. That company, as you are aware, is worked by the Eastern Company, neither the directors nor the officials receiving any remuneration for their services. An interruption of over seven weeks deprived the line of all revenue during this period, and the Eastern Company, under its agreement, has to pay the working expenses of the Black Sea Company, with the exception of Odessa, in consideration of receiving all earnings in excess of 4 per cent. on its nominal capital. The shares held by the Eastern Company were acquired some years ago at a price which, even on the past year's working, gave us a return of nearly 5 per cent., while in previous years we have had over 7 per cent. on the investment. The Eastern and South African Company's dividend this year is 8 per cent., which is the same as last year. This is a very considerable return; but I daresay you are aware that we have subsidies which supplement the traffic to some considerable extent, otherwise the depressed state of trade at the present moment would have made a difference in our returns. Fortunately though trade may get sick it never dies, and as we are now receiving 8 per cent., with improved trade we are not likely to do worse, and we may do better.

In regard to our expenditure, I may just show you a little of the fluctuations that take place. The ordinary working expenses of the Company amounted in the half year ended September, 1883, to £80,849, against £69,809 in the corresponding period of 1882, or an increase of £11,040; but showing a decrease of £6,978, as compared with the March, 1883, accounts. The increase is accounted for as follows:—General expenses in London have increased £1,573. Half of this increase is in law charges, which amounted to £925, against £150. The other items, salaries, office expenses, stationery, &c., are higher, and are caused by extra amounts paid for clerkship, printing, stationery, and other expenses, owing to the growth of the Company's system. The working expenses at the stations show an increase of £5,627. Since September, 1882, we have opened two new stations—Glasgow and Tripoli; so that this half year bears their additional expenses, besides the full half year's expenses of the Port Said station, against two months last year. The principal increase is in salaries at stations, chiefly caused by the promotions made after the Egyptian War, and sanctioned at the last general meeting of the shareholders. I may mention that there is no increase under this head when compared with March, 1883, accounts. In addition to this, the Malta-Tripoli, Triplicate Red Sea, and the Port Said cables necessitate an increased staff. We are obliged also to keep up a reserve of clerks to fill up gaps caused by resignations and so on. It is a peculiar service, and we have to train all our young men.

Sir JAMES ANDERSON: The reserve has to be kept in anticipation of sickness.

The CHAIRMAN: Yes, for sickness also, and leave of absence; because the young men in those climates have to come home occasionally, and there is a constant flow to and fro. I may mention also that during the year of the cholera in Egypt we considered it of the very highest importance to keep our staff in as comfortable a position as possible; and, in fact, to keep up their hearts so that they might do their work, as you can well understand the painful position of young men away from home surrounded by deaths occurring almost every hour—a state of things calculated to shake even the strongest minds sometimes. We felt it was wise to leave nothing undone which could keep them up. We sent some of them to the sea-side, gave them extra allowances to keep them in good health and spirits. I do not think the money thus spent was thrown away. At the same time it amounted to an important sum—no less than £935. Then we had, as you are aware, the issue of our Four per Cent. Debentures. That took a considerable amount—£2,487 for printing, advertising, and so on. Advertising alone cost us no less than £2,150. All these amounts summed up make a very considerable item, and I mention them to you as the causes of the apparently large amount of our expenditure. There is one important point that I will draw your attention to—that is, the expenses on the repair and renewal of cables. I have always stated on these occasions that if we could only keep our ships in dock, instead of keeping them at sea making repairs, it would be very beneficial to the Company. This half year I am glad to say that these expenses were only £29,520, against in 1882 £56,801, so that there is a very considerable reduction there, the decrease being £27,281. Two of our ships are at present in London, and I think I may say that they can never be better employed for the Company than when they were doing nothing and lying in dock. You will better understand (and I think it is right to mention it while I am referring to this general increase of expenditure) how it has come about when I tell you that our mileage of line is now 18,225 miles, against 16,825 miles in September, 1882. The number of our stations is 49, against 46; and the number of our staff 500, against 464, exclusive of messengers, servants, &c. You see, therefore, that we have a very large extent of cable. A great dealof that cable is laid in shallow water, which has its advantages as well as its disadvantages. Interruptions more frequently occur in shallow water from many causes, but then we know where the breaks take place, so that there is very little difficulty in repairing them.

I may mention that during the autumn, in September and October, the managing director and myself paid a visit to some of our stations. We went to Trieste, where we opened a new station, and afterwards we went to Corfu, where we also opened a new station. We next visited our station at Zante, and then we went on to Athens. We saw there were very considerable improvements and extensions to be made there, and we had been in negotiation for quite a year with the Greek Government in regard to those extensions, but the negotiations had come to a dead lock. As our agents were not getting on as they ought to we found it necessary to see the Government there, and I am glad to say that in a few hours we came to a satisfactory understanding with them. We found in the Greek Minister, M. Tricoupis, not only a great and intelligent man, but one who I believe is thoroughly patriotic—a man devoting all his time and thought to the best interests of his country. After we had arranged our business, he assured me that he did not believe it could have been settled unless we had come out and discussed the different points with him. The arrangement will, I think, result in very material benefit to the Company, not only in increased revenue, but also in extensions which will bear fruit. We went from Athens to Constantinople and found there ample scope for very considerable discussion and business. As you know, the Turks are rather slow, but I think they are beginning to wake up to some extent, and they have now in contemplation a very considerable extension of their cable system. The negotiations are pending at the present time, and therefore I need not refer further to them than to say that I believe our visit there will result in very considerable extensions, and consequently be of important benefit to the Company.

We have also extended our system through obtaining some influence in the Direct Spanish line of telegraph. We have always felt that that line in the event of war taking place in Europe again, which is not improbable, would be almost indispensable to us. We took the opportunity of securing it. The whole system will be put in thoroughly efficient order. We have not taken over the Company, for it will be still worked as an independent Company, but I think we shall be able to control it so that it will work in with the Eastern Company's great system. We have also made arrangements to purchase the undertaking of the Mediterranean Extension Telegraph Company. That Company was established long before the Eastern system, but it never progressed to any degree. It was a link in our chain, and we have secured it. The agreement, however, requires the confirmation of the Italian Government, and I have no doubt such confirmation will be granted before very long, because we are, as Governments sometimes say, on the most friendly relations with the Italian Government.

The next question I have to refer to more particularly (and no doubt you have observed by the newspapers) is that we have had some negotiations with the Egyptian Government regarding the connection of our system with Suakim. The ship is on the spot now making the connection, and when I have the pleasure of addressing you next half year I think I shall be able to make a very satisfactory statement to you in regard to that special transaction.

I have now to mention a feature showing a sort of evidence of the position which the Company occupies in the public estimation. If you remember, we have had on previous occasions some little discussion in regard to the issue of our debentures. We had 6 per cent. debentures out, and it was considered a very bold step indeed to issue debenture stock at 4 per cent. I am happy to say, however, that out of the half million we issued we have very close upon £400,000 applied for and allotted. The other £100,000 is going off by degrees, and I think getting out 4 per cent. debenture stock for a telegraph company shows the soundness of the investment. I have no hesitation in saying that, looking to the extended system we represent, it is now a real property. There is no part of our system that we cannot repair; there is no part of our system that we do not keep in thorough efficiency. The state of our ships is perhaps equal to that of any ships afloat in equipment and efficiency, so that in 24 hours, notice, or less, we could send a ship to sea in case of any repair being necessary. As I have said, however, there is nothing so satisfactory to the Board as to find that the ships are not required. Nevertheless, we cannot do without them; but the less they work the more profit to the Company.

Now, gentlemen, I think I have gone over pretty much in detail the different points, and I will conclude by moving "That the report and accounts of the directors to 30th September, 1883, submitted to this meeting be, and they are hereby received and adopted."

The Marquis of TWEEDDALE (vice-chairman): I beg to second that resolution.

The CHAIRMAN: Now I shall put the resolution to you, but if any one desires to put any questions or make any remarks before I do so I shall be very glad to listen to them.

There being no remarks on the part of the shareholders, the resolution was put to the meeting and carried unanimously.

The CHAIRMAN continuing, said: The next resolution I have to move is "That George Garden Nicol, Esq., who now retires, be and he is hereby re-elected a director of this company."

Sir JAMES ANDERSON: I have much pleasure in seconding that.

The resolution was carried unanimously.

Mr. NICOL: I beg to thank you for the honour you have done me in re-electing me, and I assure you I will continue to do my best to promote the prosperity of the Company.

The CHAIRMAN: The next resolution is "That John Denison Pender, Esq., who now retires, be, and he is hereby re-elected a director of this Company."

The Marquis of TWEEDDALE: I beg to second that motion.

The resolution was carried unanimously.

Mr. GIBB (a shareholder): I beg to move "That Mr. Henry Dever and the firm of Messrs. Quilter, Ball, Crosbie, Glegg, and Welton be, and they are hereby elected auditors of the Company for the current year, with a joint remuneration of £200."

Mr. JOHN NEWTON: I beg to second that resolution. Although the

Digitized by Google

mover has not stated the fact, it is an increase of the salary from £50 to £100, or from £100 to £200 for the year. I think the time has arrived when the work of the auditors must be largely increased, and I consider it only right that there should be some recognition of the increased work done by them, in order that there may be every inducement for the work being done efficiently.

The CHAIRMAN: I entirely endorse the remarks made by Mr. Newton, and if any honourable shareholder, when he has a few minutes to spare, would call at any time at the head office and see how the staff are packed there, and the amount of paper which has to pass through their hands, he would see that it was something very extraordinary. I may mention also that at the very first meeting of the Eastern Company I stated that the responsibility of the audit ought to be entirely with the shareholders, and that such audit ought to be carried on not half-yearly but from day to day, I may almost say, and by auditors who are recognised in the City of London as of the very highest standing. That system we have carried out, and all your accounts are carefully watched from day to day by our auditors, so that it is almost impossible for any error to occur, so strict is the investigation and so close is the audit kept. As you know, if an audit only takes place once in six months, it is very difficult to go into all the details, but as it is carried on from day to day it makes it comparatively easy at the end of the six months, and therefore I think the increased remuneration from £50 to £100 is well deserved.

The resolution was carried unanimously.

Mr. WILLIAMS: Will you permit me to make a remark as to the investments on account of the reserve fund? I notice that only about half of the reserve fund is invested. I understand that the other portion consists of money in lines, cables, and so on; but there are twenty-three investments named here, and excepting eight, one of which is Three per Cent. Consols, all the rest bear interest of 4 per cent. only. That strikes me as a very low rate of interest. Would it not be possible to increase it?

The CHAIRMAN: If you knew, Mr. Williams, the difficulty we have in getting 4 per cent., or even an approach to 4 per cent., you would be astonished—of course in a solid security. We are not allowed to take any risky security. We must have securities which we can turn into money any day, or indeed any hour on any day; and you may know what that means very well if you look at the newspapers. You will see there that you can scarcely buy North Western, or any railway debentures to pay more than 3¼ per cent. The other day in connection with a railway I have to do with, we issued debentures for something like 1,500,000 at 3½ per cent. No doubt if we were a little speculative we might improve the rate of interest, but I do not think it would be wise to make the change, or that your Board, indeed, should take any risk whatever in such a matter.

Mr. WILLIAMS: Admitting all that, is there not an alternative mode? Suppose you invested a portion of your reserve fund in, not your own shares, but in those of the sister company—the Eastern Extension Company. That is quite as good a security as any of these 4 per cent. securities.

The CHAIRMAN: In answer to that I would simply say that a telegraph system is a great chain. I have perfect confidence in that chain if kept together, but still, if any section, any material section, went wrong, it would for the moment probably derange the value of your security, and as this reserve fund is kept for the purpose of making repairs or replacing cable if necessary, we must consider it always as cash. If we hold shares in the sister company and any accident occurred at the time we wanted to sell the shares, we could not do so as freely as would be necessary without probably experiencing a considerable loss. We know the chances are in this investment we hold, that there is very little risk of loss or of gain either, but we do not know what the result would be if the money were in telegraph shares. I may give you an illustration. At the present moment competition is springing up in Atlantic telegraphy, and see how the value of Atlantic property has been changed simply by this competition! We therefore try to keep our reserve fund as much intact as possible, so that it can be regarded as hard money.

Mr. WILLIAMS: There is a vast difference between Anglo-Americans and Eastern Extensions.

The CHAIRMAN: I think the feeling of the meeting is entirely in favour of the course we pursue.

Mr. NEWTON: The shareholder quite overlooks the fact of our own debentures. I ask, as a debenture holder myself, what I should think of my property if you began to invest in shares of the sister company, or any telegraph company? It would be like a dog eating its own tail to invest in the manner suggested by that gentleman. While I am speaking, I should just like to ask a question as to the debentures. Are they an absolute mortgage on your property? Can I recommend ladies to buy them as a sound mortgage on your property?

The CHAIRMAN: I think the solicitor is the best person to answer that question.

Mr. NEWTON: It is an important question.

The CHAIRMAN: I know it is.

Mr. NEWTON: It has a considerable effect when people know that they are trustees.

The SOLICITOR (Mr. Burt): I always have pleasure in answering Mr. Newton's questions, as they are always to the point. The resolution which was passed said that the Mortgage Debenture Stock "for the time being in issue, and the interest thereon, shall rank *pari passu* as a first charge on the undertaking and revenue of the Company." I may say that this resolution was settled by Mr. Buckley, the well-known author of the book on the Companies Acts, very carefully, with a view to see that there was an effective charge on the part of the holders of this stock on the Company's undertaking. It would be impossible to assign the property to trustees, as we have property in Egypt and other places abroad; but, nevertheless, the stock is a first charge on the undertaking and the revenue of the Company.

A SHAREHOLDER: Could there be a receiver under that resolution?

The SOLICITOR: I have no doubt in the event of the contingency happening you could get a receiver appointed.

A SHAREHOLDER: That is very satisfactory to us, as it makes the stock equal to a mortgage.

A SHAREHOLDER: It is a mortgage.

This concluded the business of the ordinary meeting.

The CHAIRMAN: Now we have to consider the business of the extraordinary meeting, and the secretary will read the notice convening the meeting.

The SECRETARY having read the notice,

The CHAIRMAN said: Gentlemen, the resolution is, "That this meeting approves and sanctions the agreement now submitted, dated 8th January, 1884, and made between the Mediterranean Extension Telegraph Company (Limited) and the Hon. Ashley Ponsonby and Mr. J. G. Griffiths, the liquidators, of the one part, and the Eastern Telegraph Company (Limited) of the other part, for the purchase by the latter company of the telegraph lines and concessions of the Mediterranean Extension Telegraph Company, and authorises the directors to do all things which they may deem necessary and expedient for carrying the same into effect." As I have just stated, this resolution is for the purchase of that company's undertaking. We have to get the approval of the Italian Government. The agreement has not yet been approved by the Italian Government, but getting your approval to-day is another step towards the completion of it. Mr. Burt will, if you desire it, read the agreement, but it is a regular legal document, which you may not consider necessary to have read; but that remains with the meeting.

The SOLICITOR: The substance of it is, that we buy the cables and concessions of the Mediterranean Company for the sum of £35,000 of the 4 per cent. Mortgage Debenture Stock of the Company. There are provisions made for postponing the completion of the purchase till the approval of the Italian Government is obtained, and until possession of the cables is obtained by the Company; the vendors, that is, the Mediterranean Company, are to keep them in repair and are to hand them over to this Company in good working order. That is the substance of the agreement.

Mr. WILLIAMS: Does that £35,000 form a new stock?

The SOLICITOR: It is £35,000 of the Four per Cent. Stock to which the chairman has referred.

The CHAIRMAN: Of which there is still unissued £100,000.

Mr. WILLIAMS: Is there any guarantee of the Italian Government for the remainder of the term, and how long has it to run?

The CHAIRMAN: I think the concession has eight or ten years to run.

The SOLICITOR: With power to extend it by arrangement.

Mr. WILLIAMS: In the meantime is the Italian Government bound pay any guarantee they pay to the Mediterranean Company?

The CHAIRMAN: They do not pay any guarantee.

Mr. WILLIAMS: If the Italian Government do not approve of this will it fall to the ground?

The CHAIRMAN: We do not contemplate that, as we have always the alternative of working the Company as it exists at the present time till the expiry of the concession. We have always that.

The VICE-CHAIRMAN: I beg to second the resolution.

The CHAIRMAN put the motion in the usual way, and declared it to be carried unanimously, adding that this completed the business of the day.

Mr. WILLIAMS: Before the meeting separates I should beg leave to propose a vote of thanks to yourself as chairman and to the directors of the Company, and in doing so I would beg to observe that I am one of your very oldest shareholders. I have held an interest in every one of the companies out of which this Company was constructed; and I am not a very small shareholder either. I would beg to state that I think the management of the Company is very admirable indeed; but you make very tight bargains, and when I state that I am a shareholder myself in the Mediterranean Extension Company you will see that I feel that [laughter].

Mr. NEWTON: I beg to second that motion.

The SOLICITOR: Gentlemen, is it your pleasure that that resolution be carried? All in favour of it will please signify the same in the usual manner.

The resolution was carried unanimously.

The CHAIRMAN: Gentlemen, on behalf of my colleagues and myself I beg to thank you. I can only assure you that, were it one's own private business, the business of this Company could not be attended to more carefully than it is. We are all proud of the position to which we have attained, and it is our daily desire not only to maintain that position but to carry it higher if we possibly can. I have told you on many occasions that we are now an absolute necessity to the Governments of Europe—that our submarine system of telegraphy is of such importance that they cannot do without us. I mention that not in the way of boasting, but to show you how useful the institution has become, and that it is not only appreciated by the whole mercantile community, but in the political world it is an absolute necessity. It tends to maintain peace, because it tends to remove on many occasions irritation, which might grow were it to extend over any length of time. I can therefore see a very fine future for submarine telegraph property; and as long as it is in the hands of the gentlemen who sit on this side of the table I am perfectly sure that it will be well attended to and well managed. I hope the next time I have the pleasure of addressing you I shall be able to make a more complete statement as to the real position of the property, and show you how sound and profitable the Company is becoming. I beg to thank you.

The proceedings then terminated.

## ANGLO-AMERICAN TELEGRAPH COMPANY.

Report of the directors to the ordinary general half-yearly meeting of the proprietors, to be held at the City Terminus Hotel, Cannon-street, E.C., on Friday, the 8th February, 1884, at noon precisely. The total receipts from the 1st of July to the 31st December, 1883, including a balance of £13,263 14s. 1d. brought forward from the last account, amount to £259,814 11s. 7d. The traffic receipts show a decrease of £10,089 as compared with the corresponding period of last year. The total expenses of the half year, including repair of cables, income-tax, &c., as shown by the revenue account, amount to £79,758 1s. Of this amount £18,100 13s. 9d., representing the cost of the renewals, additions, and improvements to the steamship "Minia," has been charged to the renewal fund. The directors, under the powers conferred upon them by the Articles of Association, have, before declaring the net profits, set apart the sum of £75,000 to the renewal fund, leaving an available balance of £123,157 4s. 1d. Interim dividends of 15s. per cent. on the ordinary stock, and 30s. per cent on the preferred stock, free of income-tax, were paid on the 1st November

Digitized by Google

last, absorbing £52,500, leaving a balance of £70,657 4s. 1d., out of which the directors recommend the proprietors to declare final dividends, free of income-tax, of 20s. per cent. on the ordinary stock, 30s. per cent. on the preferred stock, and 10s. per cent. on the deferred stock, amounting to £70,000, making a total distribution for the year ended the 31st December, 1883, of £3 5s. per cent. on the ordinary stock, £6 per cent. on the preferred ordinary stock, and 10s. per cent. on the deferred stock, leaving a balance of £657 4s. 1d. to be carried forward to the next account. The Company's repairing steamship "Minia" has been engaged during a portion of the past half year in the repair of the Duxbury cable, which was broken four times between the 4th July and the 13th August. In accordance with the decision of the directors, as announced in the last half-yearly report, the "Minia" returned to London on the 17th September last, for the purpose of taking in new boilers, and for the renewal of, and addition to, such parts of her hull, machinery, and picking-up gear as were found to be necessary, after an absence from this country of more than seven years. The ship has undergone a thorough overhaul throughout; she has been surveyed both by the Board of Trade and Lloyd's, re-classified in the books of the latter society, and is now capable of undertaking cable work in any depth of water. On the 13th November last the cable laid in 1872 between Placentia and St. Pierre was broken near to the latter place. On the 17th November a timber ship sunk in St. Pierre Harbour upon the shore ends of the Brest-St. Pierre, and St. Pierre-Duxbury cables, injuring the former, and entirely interrupting communication by the latter. On the 19th November the cable laid in 1880 was broken about eighteen miles from Valentia, Ireland, in eighty fathoms of water. With the exception of the faults above mentioned, which have not interfered with the due and prompt transmission of the traffic, the Company's system of cables and land lines is in good working order and condition. The ss. "Minia" left Gravesend on the 2nd inst. to repair the cables just enumerated, having commenced with the fault in the 1880 cable off Ireland, communication upon which was restored on the 16th inst. The competition referred to in the report of the directors dated the 1st February, 1883, appears to have assumed definite proportions. Mr. James Gordon Bennett, proprietor of the *New York Herald*, and Mr. John W. Mackay, are stated to have given orders to a well-known firm of cable manufacturers, for the making and laying of the two new cables between this country and the United States of America, and a company has been incorporated in the United States, entitled the Commercial Company, to take over and work the cables. In accordance with the Articles of Association, two directors of the Company, Sir Daniel Gooch, Bart., M.P., and Francis A. Bevan, Esq., retire at this meeting, and being eligible, offer themselves for re-election. Mr. Joshua Dean and Mr. Francis Glass, the auditors, also retire and offer themselves for re-election.

## THE SWAN UNITED ELECTRIC LIGHT COMPANY (LIMITED).

An extraordinary general meeting of this Company was held at the Guildhall Tavern, Gresham-street, on Tuesday, the 29th ult., for the purpose of considering and of passing (if approved) the following resolution:—"That the Bill which is proposed to be introduced into Parliament in the ensuing Session, intituled 'A Bill to transfer to the Edison and Swan United Electric Light Company (Limited) certain rights, powers, and obligations of the Edison Electric Light Company (Limited) and of the Swan United Electric Light Company (Limited), and for other purposes,' is approved, subject to such additions, alterations, and variations as Parliament may think fit to make therein."

Mr. J. S. Forbes occupied the chair.

The notice calling the meeting having been read,

The CHAIRMAN said: Gentlemen, this is a meeting of a purely formal kind, held in pursuance of the standing orders of Parliament. It will be quite within the recollection of the proprietors that very recently they have amalgamated their interests with the Edison Company. In the Session immediately before the amalgamation was carried into effect certain provisional orders had to be applied for to Parliament, under which the Swan Company were authorised to light up certain parts of London, the Edison Company other parts. One condition of a provisional order is that it should not be assigned to third parties without the sanction of the Board of Trade, and one difficulty has arisen as to this. The Swan Company having fused with the Edison Company under a stipulation which throws into a common pot their assets and obligations there is this point of doubtful legality, namely, whether the Swan Company can put their provisional orders into one common pot, or whether the Edison can—whether in point of fact it is an assignment which can be carried out without the sanction of the Board of Trade. Well, we have reason to believe that a difficulty of the kind might be raised, and as one has to foresee difficulties to prevent obstruction we thought it expedient, acting upon the advice of legal gentlemen who are conversant with such matters, to apply to Parliament for power to remove all questions of doubt about it, because you will see it would be very awkward indeed if the Board of Trade—although from the wording of the provisional order they had an implied right to approve of the assignment—came to the conclusion that they had no such legal right. It seems, however, to me very odd that provisional orders should be drawn so closely as to imply a power in ordinary express language, and not confer it in fact. We have had to meet the possibility of that question being raised, and the Bill in effect carries out that object—that is to say, that the companies that are fused or amalgamated under agreement of the respective proprietors may carry out these orders, and that neither company, therefore, is left in a position to carry out these orders separately, and that it should be for the benefit of all parties that they should be carried out by the United Company, who seek sanction for that course being adopted. That is really the whole story. During the progress of the Edison order there was a great conflict between them and some other lighting company, called I think the Telegraph Construction and Maintenance Company. There were two Richmonds in the field, in fact, in reference to a portion of one of the districts, and in order to prevent an expensive contest before a committee it was agreed between the two parties, in the event of the two provisional orders being passed, that the Electric Company should light a portion of the area. It is necessary, upon the very same grounds, to clear up any doubt as to the power of the Edison Company, as it does exist, assigning any portion of its powers to a third company, and that case is met in the Bill. These two matters form, in short, the subject of the Bill and the meeting. He concluded by moving the resolution already quoted at the beginning of the report.

Mr. JAS. C. STEVENSON, M.P.: Mr. Chairman, I have great pleasure in seconding the resolution which you have submitted to the shareholders of the Edison and Swan United Electric Company. Although you stated that this was a merely formal meeting, yet I think by this resolution, which I hope will be unanimously passed, you will transfer actually the powers you obtained by the provisional order you acquired last Session of Parliament to the combined companies in order that they may carry out those powers with vigour and discretion. I am quite satisfied that the United Company will exercise with advantage those powers which this Act of Parliament will confer upon them when it is passed. Our main business hitherto has been that of manufacturing lamps. It is evident that the best foundation for such a manufacture is to create a demand for those lamps. The demand hitherto has been very much for what you may call detached and private installations, sea-going passenger steamers, and various other private undertakings. The benefit of electric lighting will never be fully decided, its advantages to the public realised, and the demand for the manufacture of these lamps brought up to its proper proportion, until we are able to furnish the public with the electric light in the same way as the gas and water companies furnish them with gas and water, by laying mains through the streets; and while at present it is a very serious matter for any person to have his house lighted up with electricity—because it compels him to have his own private source of power—I am sure there is a great future for the electric light [hear, hear] if we can give the public the current in the same way and with as little trouble as they are supplied with gas and water. In that spirit we took advantage of the privileges conferred on the Board of Trade to give powers to such companies under the Electric Lighting Act. However, this technical difficulty which the chairman has explained has arisen. But I think we can very shortly give the public the benefit of the experience which we believe they only require to enjoy in order to create the demand for this mode of lighting—one of the most interesting discoveries of modern times, which is destined to have a great future. I have great pleasure in heartily seconding the resolution.

The CHAIRMAN: Unless any honourable proprietor wishes to ask any questions or elicit any further information I will at once proceed to put the resolution I have moved, and which has been so ably seconded by my hon. colleague the member for South Shields, whose confidence about the future of this light I am sure all will endorse. He has adverted to the necessity of proceeding with the matter with a great deal of prudence. I think on this side of the table we are fully impressed with the importance of that. I have no doubt there is a great future for electric lighting, but we have a great deal to learn, and every step must be taken with circumspection. Up to the present time these companies appear to have made no serious error. They have had, of course, like all new things, to buy experience. Having bought it we must turn it to the best advantage, and although not at all losing any opportunity of furthering the interests of the proprietors by going to work, we must take great care that every step is a prudent step calculated to land us where we should get profitable lighting. He concluded by putting the resolution, which was carried unanimously, and afterwards reminded the shareholders that they would be convened on a future day in accordance with the provisions of the Joint Stock Companies Act for the purpose of confirming the resolution. The proceedings then terminated.

## THE ANGLO-AMERICAN BRUSH ELECTRIC LIGHT CORPORATION (LIMITED).

Immediately after the ordinary business is transacted the subjoined resolution will be proposed as special business:—"That the capital of the Corporation, which now consists of £800,000, divided into 80,000 shares of £10 each, of which 13,701 shares have been issued, and are fully paid, and 26,999 shares have been issued and have £8 per share paid, or called up thereon, be reduced to £400,000, divided into 80,000 shares of £5 each, and that such reduction be effected by cancelling paid-up capital which has been lost or is unrepresented by available assets, to the extent of £5 per share, upon each of the 40,700 shares which have been issued, and by reducing the nominal amount of all the unissued shares from £10 to £5." Should the resolution be passed, either with or without modification, by the required majority, it will be submitted for confirmation, as a special resolution, to an extraordinary meeting, which will be subsequently convened.

The directors beg to submit to the shareholders the annual report and balance-sheet for the year ended 31st December, 1883. The shareholders are already aware that soon after the last general meeting one half of the directors who constituted the Board retired, and that in May last Lord Thurlow, the present chairman, and Mr. H. C. Gibbs, accepted seats at the Board; and later in the year it was augmented by Mr. Edward Woods, Vice-President of the Institution of Civil Engineers. One of the first duties that devolved upon the Board as reconstituted was to appoint successors to the late general manager, the secretary, and the engineer. They appointed Mr. Frank Wynne as general manager and engineer, and Mr. Emile Garcke as secretary. The Board found that considerable re-organisation of the Corporation's business was desirable, and it was also thought necessary, after a careful investigation of the books and accounts, to remodel the system of bookkeeping. An eminent firm of accountants, Messrs. Cooper Brothers and Co., have, at the request of the Board, reported on the state of the books. In their report on the system of bookkeeping as introduced by the new management, they state that they "consider that the new system of accounts in the office, and in the factory, is generally good, and apparently meets the requirements of the business of the Corporation." It was thought well to consummate this re-arrangement of the Corporation before issuing the balance-sheet for the past year; and in submitting the latter to the shareholders, the directors, after consultation with counsel and with

Digitized by Google

Messrs. Cooper Brothers and Co., have decided to deal with the accounts as hereafter explained, debiting profit and loss account with the various large amounts shown. This course was chiefly rendered necessary by the fact that in the accounts, as made up for 1882, no provision appeared for subsequent fluctuations in the value of those assets of the Corporation which were more or less subject to variation, and with a view to avoiding the results of the manufacturing operations being affected in future by circumstances not connected therewith the Board have decided to debit revenue account at once and for all time with full provision for all such items as tend to uncertainty. For these reasons the value of the whole of the shares held by the Corporation in the subsidiary companies have been provided for. Some of these have been surrendered, but the Corporation is still either possessed of, or entitled to, shares to the amount of £99,200. The proposed adjustment also includes an amount of £51,632 10s., which is treated as paid under the settlement of accounts with Mr. Lane-Fox, but which is, for the most part, merely a reversal of items in last year's balance-sheet. Other amounts augmenting the adverse balance will be explained later on, and are in chief the following:—Liquidation of accounts, £31,069 19s. 1d.; amount written off book value of stocks £16,058 3s. 7d., and special reductions of stocks and patents referred to later. It will be seen, therefore, even without further details, that the largest items in no way properly belong to the normal profit and loss account, being entirely outside the Corporation's business for the year. In order that this large adverse balance may not stand in the way of the payment of dividends in future, and with a view to placing the Corporation in a better financial position, the Board recommend that such a reduction of the capital be made as will admit of the elimination of this deficit from the balance-sheet. The Board have not only written off every doubtful asset, but have made the most ample provision for all contingencies, in the hope that this will free the balance-sheet from any elements of uncertainty, and contribute to regularity in the payment of dividends in future. The efforts of the Board have been earnestly directed to freeing the Corporation from the annoyance of expensive and vexatious litigation, and from all the misunderstandings affecting its relations with some of the subsidiary companies, and with Mr. Lane-Fox; and it affords the directors much satisfaction to be able to congratulate the shareholders upon the successful result of their negotiations, which proved exceedingly difficult and protracted. In view of the provisions of the Electric Lighting Act, 1882, introduced subsequently to the granting of the licenses to the subsidiary companies, the directors felt it to be absolutely necessary and incumbent upon them to make alterations in some cases in the stringent clauses of those licenses which bound the licensees to use only Brush and Lane-Fox apparatus, and thus disqualified them from complying with the provisions of the Act. Moreover the Corporation had in view the desirability of securing to themselves the power to supply Brush and Lane-Fox apparatus in the districts of those companies. Recognising also that the licensees had in same cases paid large sums in cash for the exclusive Brush licenses, the directors considered it politic and equitable to agree to pay a royalty on certain apparatus sold by the Corporation in the licensees' districts, and the Corporation have accordingly entered into agreements with the Hammond Electric Light and Power Supply Company, the Metropolitan Brush Electric Light and Power Company, the Provincial Brush Electric Light Company, and the South Eastern Brush Electric Light Company, to carry out such arrangements. The Corporation are thus enabled to undertake any business in those important districts. All allegations and charges made against the Corporation by the Hammond Electric Light and Power Supply Company, in the matter of the Lane-Fox patents, having been unconditionally withdrawn and abandoned, as being unsustainable, the action brought by the Corporation against that Company has been settled on a basis both honourable and satisfactory to the Corporation. The result of the settlement is that certain apparatus, part of which was not in exact accordance with contract, is taken back by the Corporation at net invoice prices, the Hammond Company contracting to re-purchase from the Corporation apparatus to an equal amount. The Hammond Company have paid the Corporation an amount in cash, and the remaining items of account have been adjusted. The various large money claims set up by the Hammond Company have been abandoned, and the directors are glad to say that good feeling has been restored between the two companies, and they look forward to a considerable renewal of business. The shareholders will recollect that in 1882 Mr. Lane-Fox undertook to re-purchase from the Corporation for a sum of £50,000 certain patents, originally acquired from him, and known as his distribution patents. In part payment of this sum, the Corporation was entitled to retain any sum due in account with Mr. Lane-Fox, which sum was estimated at nearly £14,000. Mr. Lane-Fox, however, maintained that a much larger sum was due to him, and cross actions were pending between him and the Corporation. As the amount payable to the Corporation under the abovementioned arrangement was a very large one, and as the Corporation understood that Mr. Lane-Fox had not been successful in effecting a re-sale, upon the result of which he counted to enable him to settle the claim of the Corporation, and as, moreover, the Corporation also considered that it would be an advantage to them to be in a position to release their licensees if necessary from the covenant binding them to exclusively sell the Lane-Fox lamp, the directors deemed it advisable to enter into a compromise with Mr. Lane-Fox, whereby the Corporation retained all moneys due to him in their hands, and subject to the said existing rights of the Corporation's licensees and purchasers Mr. Lane-Fox took back his patents and agreed to grant the Corporation a full and free license to manufacture, sell and use, and to permit their customers in the United Kingdom to use and employ all his inventions connected with electricity, and any improvements that might be made therein. He further undertook to pay to the Corporation 20 per cent of any profits which might accrue to him in respect of the sale or use of any of his patents until the Corporation had received the sum of £20,000. In completing this arrangement the Corporation agreed to transfer to Mr. Lane-Fox £14,000 in shares of the International Electric Company, and to make him a cash advance in respect of which they have a first charge on all his electrical patents. The Board feel satisfied that in making this settlement a tedious and costly litigation has been satisfactorily disposed of. The action brought by the owners of the Gramme patent against the Corporation in 1882 is not being actively proceeded with by the plaintiffs. On the contrary, the Corporation have successfully applied for security for their costs. The called-up capital has been increased by £26,999, the amount of the call made in August last. The total liabilities, including ample provision for all disputed claims upon the Corporation, now stand at only £7,888 0s. 1d. In this respect the position of the Corporation compares most favourably with the corresponding period of the previous year. The value of the patents is shown at the figure to which it was reduced at the last general meeting, plus £758 16s. 10d., the amount paid for annuities during the year, and the directors propose that this asset be reduced to £25,000. Property and plant stand at £57,082 19s. 10d., a figure which the directors consider represents a minimum valuation of this asset.

In order the better to elucidate the accounts more particularly referred to in paragraphs 5 to 9, which are more or less incidental to the former engagements of the Corporation, and those exclusively relating to the past year's operations, separate profit and loss accounts are shown and distinguished as I. and II. respectively. The first item is "Liquidation of Accounts with Mr. Lane-Fox, £51,632 10s." As already explained, this item must be considered in conjunction with the amount of £50,000 included in the balance brought forward from last year, and appearing on the opposite side of the account. It will be seen that the Corporation have under this settlement with Mr. Lane-Fox retained the sum of about £14,000 Mr. Lane-Fox was entitled to in cash, and have given him £14,000 in shares of the International Electric Company. As a result of the winding up of the Brush Electric Light and Power Company of Scotland and of the Dublin Electric Light Company, the licenses for Scotland and Dublin have reverted to the Corporation, and, on the other hand, the shares held by the Corporation in the Scottish Company have been surrendered. Arrangements have already been made to carry out an active canvass in Scotland, and the directors see every prospect of being able to establish a large and remunerative business there. An agreement has been concluded by the Alliance and Dublin Consumers' Gas Company under which the Company have acquired the plant of the late Dublin Electric Light Company, and a license to use Brush and Lane-Fox apparatus. The Corporation are not, however, precluded from doing business in Dublin. The directors have reason to hope that this arrangement will prove advantageous to all interested, indicating as it does that the gas companies are at last, though tardily, recognising the vital importance of identifying themselves with electric lighting. The next item "To liquidation of accounts £31,069 19s. 1d.," is the result of the liquidation and part relinquishment of sundry claims; the item also includes a large amount written off in respect of bad debts, and ample provision against loss in the remaining litigation and any possible contingencies. The item "To amount written off book value of stocks, £16,058 3s. 7d.," represents the deficiency between the value of the stock as per survey, and the value according to the ledgers, which is to be attributed to the former absence of proper factory books, and to the diminished value of certain electrical apparatus, of which a very large stock was manufactured in 1882. The directors propose that stocks be further reduced by 50 per cent., the extent to which this asset is considered at present unavailable. The directors, after consultation with the firm of accountants already mentioned, have set aside the amount of £99,200 as provision against the shares held by the Corporation in the subsidiary Brush Companies, and any variation that may hereafter occur in the value of these shares will not affect the amount rendered available for dividends as the result of the manufacturing operations. Profit and Loss Account II. represents the net result of the year's operations. It affords the directors much satisfaction that their efforts to reduce the expenses and re-organise the business have been in the highest degree successful. The general charges are 50 per cent loss in the last quarter than they were in the first, and the economy effected in other departments is equally considerable;—*e. g.*, while the volume of business during the last half year has exceeded that of the first half by about 70 per cent., the amount of wages paid, and quantity of material consumed in manufacture, have been relatively reduced. In connection with this, the directors would mention that the removal of the incandescence lamp department from Portpool-lane to the Victoria Works is now on the point of being completed. The directors rely on this concentration of departments to effect a large saving, and inasmuch as the vacated building is situated in a very rising locality, the directors have every reason to believe that they will be able to dispose of the lease at a profit. The deficit shown in the accounts is, as already explained, chiefly due to the manner in which the directors have deemed it advisable to deal with the shares in the subsidiary companies, to adjustments of accounts consequent upon the settlements that have been effected with Mr. Lane-Fox and others, bad debts written off, and special reductions of stocks and patents accounts. It will be impossible so long as this large balance remains to the debit of profit and loss account for the Corporation to distribute as dividends the profits which result from its manufacturing business: and the directors recommend after a most anxious consideration of the position, that the shares of the Corporation be reduced by £5 each. A resolution to this effect will be submitted to the general meeting. If this arrangement is sanctioned, the Corporation would be enabled to apply to the payment of dividends any profits, earned during the current and future years, in excess of the amount of £1,616 3s. 2d. to which the adverse balance would then be reduced; and the position of the Corporation would, after the reduction of capital proposed, be briefly as follows:

| Dr. | £ s. d. | Cr. | £ s. d |
|---|---|---|---|
| Capital, viz. 13,701 shares £5 each fully paid ..... £68,505 | | Patents..... | 25,000 0 0 |
| 26,999 shares £5 each, £3 paid.. 80,997 | | Plant and buildings ... | 57,082 19 10 |
| 149,502 | | Stock..... | 47,190 1 3 |
| Less calls unpaid . 1,225 | | Debtors ..... | 21,043 3 9 |
| | 148,277 0 0 | Cash ..... | 4,232 12 1 |
| Creditors ..... | 7,888 0 1 | Shares ..... | 99,200 0 0 |
| Provision against shares | 99,200 0 0 | Balance..... | 1,616 3 2 |
| | £255,365 0 1 | | £255,365 0 1 |

In the event of this recommendation being accepted by the shareholders, the Board propose that the holders of the shares upon which £8 only have been paid should have the option of placing themselves in a position of equality with the holders of the fully paid shares, by paying off the remaining liability upon their shares in advance of calls.

INSULATED ELECTRICAL WIRE, Silk, Cotton, or India-rubber covered. Conductivity guaranteed. German Silver Wires for Resistance. Braided Handle Cord, Silk Cord for Electric Bells, &c.—WILLIAM RICKARD, Derby London Agent (stock kept), EDWIN HOLLOWAY, 2, Gutter-lane, E.C.

FURNESS RAILWAY TELEGRAPHS.

TO ELECTRICIANS AND CONTRACTORS.

Messrs. NORMAN and SON, of Barrow-in-Furness, are prepared to negotiate the TRANSFER of their CONTRACT for the MAINTENANCE of the Entire System of TELEGRAPHS on the FURNESS RAILWAYS.

ELECTRICAL ENGINEER, with considerable experience in Electric Lighting, both Arc and Incandescent, requires suitable EMPLOYMENT.—Address M. C., office of THE ELECTRICIAN, 396, Strand.

EMPLOYMENT WANTED in any branch connected with electricity by a young man who has been used to workmen, and has passed the South Kensington exam. in electricity and magnetism.—Address WILLIAM ELLIOTT, Stroud, Gloucester.

WANTED, a good G. P. JOINTER, accustomed to underground telegraph work. None but experienced hands need apply.—United Telephone Company, Finsbury Market, E.C.

C. A. CARUS-WILSON, ELECTRICAL ENGINEER, Mathematical Scholar at the Government Engineering College; lately Electrical Engineer to the International Electric Company, Vienna; also La Compagnie Belge et Hollandaise d'Electricité, Brussels; and the Anglo-American Brush Electric Light Corporation, London. Complete Working Specifications prepared, and Installations of Electric Light personally superintended, directed, and worked. Testimonials, with list of places already lighted, on application.—11, Queen Victoria-street, E.C.

MAGNUS VOLK,
ELECTRICIAN TO THE BRIGHTON CORPORATION,
MANUFACTURER AND CONTRACTOR FOR
ELECTRIC LIGHTING, ELECTRIC RAILWAYS, ELECTRIC APPLIANCES.
DITCHLING RISE TELEGRAPH WORKS,
BRIGHTON.

READY FEBRUARY 9.
THE
ELECTRICIANS' DIRECTORY
FOR 1884
WILL BE PUBLISHED AT
1, SALISBURY COURT, FLEET STREET, E.C.
CONTAINS
A Directory of Electricians,
Manufacturers of Electrical Apparatus, &c.,
Electric Light Companies,
A List of the Local Authorities in Town and Country, with their Officials,
Foreign Telegraph Tariffs,
A List of Cable Ships,
And other Useful Information.

J. EDMUNDSON and CO.,
ENGINEERS AND ELECTRICIANS,
19, GREAT GEORGE STREET, WESTMINSTER, S.W.
MANUFACTURERS OF
ELECTROLIERS, PENDANTS, AND BRACKETS, AND ALL DESCRIPTIONS OF ELECTRIC LIGHT FITTINGS.
SPECIAL AGENTS FOR HEDGE'S PATENT SAFETY FUSES.
THE "SWAN" INCANDESCENT LAMP.
J. EDMUNDSON and CO. having been appointed as SPECIAL AGENTS for the Exhibition and Sale of the SWAN INCANDESCENT LAMPS, are prepared to supply these in any quantities. Also to furnish Estimates for fitting them up complete with all necessary apparatus. The Swan Lamps may always be seen in action at their Show Rooms.

## NOTES.

SOUAKIM.—The rate to Souakim per Eastern Telegraph Company's cable is 2s. 6d. per word.

ELECTRIC LIGHTING FOR THEATRES.—It is stated that the Theatre Royal, Montreal, is to be illuminated by the electric light.

CABLES INTERRUPTED.—The cables between England and Holland, and between England and Belgium, are interrupted.

BRAZILIAN SUBMARINE TELEGRAPH COMPANY.—The traffic receipts of this company for the week ended 1st inst. amounted to £2,895.

WEST COAST OF AMERICA TELEGRAPH COMPANY.—The gross earnings of this company for the month ending January 31st, 1884, were £4,500.

HARROGATE ELECTRO-HYDROPATHIC COMPANY.—Mr. Justice Chitty has made an order for the winding up of this company, and allowed the costs of the petitioner.

EGYPT AND THE SOUDAN.—According to the latest news from Egypt, received on Thursday, the wires were cut between Khartoum and Berber, and between Massowah and Kassala.

DIRECT SPANISH TELEGRAPH COMPANY.—The estimated traffic receipts of this company for the month of January, 1884, are £2,045, against £1,672 in the corresponding period of last year.

UNDERGROUND TELEPHONE CABLE.—The Western Electric Company have constructed a 50-double wire underground telephone cable for the Chesapeake and Potomac Company's use in Washington, U.S.A.

AWARD.—Messrs. Woodhouse and Rawson have been awarded a diploma of honour by the Committee of the International Fisheries Exhibition for their incandescent lamps which were exhibited there.

ELECTRIC LIGHTING IN BOSTON, U.S.—On January 1, 1883, there were 116 electric lights in the streets of Boston, U.S.A., and its suburbs; on the 1st January of this year the number had increased to 381.

GULCHER ELECTRIC LIGHT COMPANY.—An extraordinary general meeting of this company was held on Friday, the 1st inst. No reporters were admitted, but we believe the object of the meeting was reduction of capital.

EASTERN EXTENSION TELEGRAPH COMPANY.—The traffic receipts of this company for the month of January, 1884, amounted to £35,331, and to £32,822 for the corresponding period of 1883, being an increase of £2,509.

ANOTHER REDUCTION.—It is stated that the South Metropolitan Gas Company have decided to reduce the price of gas from 2s. 10d. to 2s. 8d. per 1,000 feet. This reduction will take effect from the 1st of January last.

GREAT NORTHERN TELEGRAPH COMPANY.—The traffic receipts of this company for January, 1884, were £19,360; during the corresponding month of 1883 they were £18,390, against £17,110 for the same period of 1882.

BRUSH ELECTRIC LIGHT COMPANY OF AUSTRALASIA.—A general meeting of the members of this company will be held at No. 4, Copthall-buildings, E.C., on the 4th March, at twelve noon, to receive the liquidators' account.

WESTERN AND BRAZILIAN TELEGRAPH COMPANY.—The traffic receipts of this company for the week ending 1st February, 1884, were £2,100, after deducting the "fifth" of the gross receipts payable to the London Platino-Brazilian Telegraph Company.

VARYING THE INTERNAL RESISTANCE OF BATTERIES.—We are informed that Mr. J. S. Beeman, in the course of some recent experiments, found that the internal resistance of a battery could be regulated at will by simply dropping methylated spirits or alcohol into it.

WEST INDIA AND PANAMA TELEGRAPH COMPANY.—The estimated traffic receipts of this company for the half month ending the 31st January are £2,867, as compared with £2,588 in the corresponding period of 1883. The October receipts, estimated at £4,524, realised £4,660.

TELEGRAPH CONSTRUCTION AND MAINTENANCE COMPANY.—The directors of this company notify that, subject to the audit of the accounts, they propose paying a dividend of 15 per cent (£1 16s. per share), in addition to the ad-interim dividend of 5 per cent. already paid, making 20 per cent. for the year 1883.

GLASGOW UNIVERSITY "CONVERSAZIONE."—Last week the Bute and Randolph Halls of Glasgow University were publicly opened by a *conversazione* given by the professors. The whole suite of rooms were brilliantly illuminated by the electric light, eight arc and sixty-two incandescent lamps being employed.

THE TELEPHONE IN FRANCE.—On the 31st ult. the number of subscribers to the various exchanges of the Société Générale des Téléphones was 5,176, being an increase of 1,051 as compared with the same date of 1883. The number of subscribers in Paris has increased by 629 within the year, and now stands at 3,321.

THE SOCIETY OF TELEGRAPH ENGINEERS.—The next meeting of the society will be held at 25, Great George-street, at 8 p.m., on Thursday, February 14th, when the following paper will be read:—"On some new Instruments for Indicating Current and Electromotive Force," by R. E. Crompton and Gisbert Kapp, members.

CUBA SUBMARINE TELEGRAPH COMPANY.—The number of messages passing over the lines of this company during the month of January was 3,291, estimated to produce £3,000, against 2,954 messages, producing £2,829 in the corresponding month of last year. The traffic receipts for the month of October, estimated at £2,700, realised £2,744.

THE RECENT CELESTIAL PHENOMENA.—At the request of the Royal Society, the Maritime Observatory of Hamburg will forward to London all the scientific information at their disposal in regard to the remarkable sunsets which were observed towards the close of last year, in order to assist the society in the compilation of their projected work in regard to physical phenomena.

LONDON AND PROVINCIAL ELECTRIC LIGHTING COMPANY.—Mr. Justice Chitty has appointed Mr. W. L. Grimwade, of 32, Queen Victoria-street, E.C., official liquidator of this company. Notice has been given that all creditors are to send in their names and claims to Mr. Grimwade on or before the 25th instant. The 12th March has been fixed for hearing and adjudicating on the debts and claims.

ERRATUM.—In a note on the opening of the Technical Schools, at Nottingham, in our last issue, we stated, in speaking of some of the incandescent lamps exhibited on the occasion, that they were "silvered over their upper halves by Messrs. Abbey and Co., in accordance with the patent of Messrs. Lorrain and Maher." The name of the latter gentleman should have read Waters instead of Maher.

Digitized by Google

THE BRUSH MIDLAND COMPANY.—The following notice appears in a recent *Gazette* :—"A petition for confirming a resolution reducing the capital of the above company from £250.000 to £70,500, was, on the 18th January, presented to the High Court of Justice, Chancery Division, and is now pending before Mr. Justice Pearson, and the list of creditors of the company is to be made out as for the 11th March."

OURSELVES.—The pressure on our space has again compelled us to withhold several interesting letters, to curtail the space occupied by our "Notes," and to postpone the conclusion of Mr. Reckenzaun's paper. We would remind our readers that next week's issue will be published at our new offices, 1, Salisbury-court, Fleet-street, E.C., so that all letters intended for insertion in that issue should be sent to that address.

THE TELEPHONE AT RAMSGATE.—As we stated in a recent issue, the Ramsgate Improvement Commissioners have recently had telephonic communication effected between the police station and water works, with a special view to its utility in case of fire. The line was used for the first time in this connection on the 1st inst., when a fire broke out in Ramsgate at 8:20 p.m. Information was at once telephoned from the police station to the water works, and the latter promptly got up a high pressure in the mains, so saving a ot of valuable time.

METROPOLITAN BRUSH COMPANY.—The secretary of this company writes to a daily paper as follows:—"The best reply to the circular which the committee have just issued (dated 5th instant) is to ask the shareholders who are not satisfied with the course taken by the Board to come to the meeting on the 12th instant, when a full answer will be given to the accusations, &c., contained in the circular above referred to; they can then judge for themselves, after hearing both sides. It was because the Board felt that faith had not been kept with them that they considered it necessary to break with the committee, to whom it is now no doubt more comfortable to cry *tu quoque* than *peccavi*."

A CABLE TO LUNDY ISLAND.—With reference to the note in our issue of January 26, under this head, in which we stated that a scheme was on foot amongst the shipowners of Bristol and Cardiff to lay a cable to Lundy Island, and that Newport was somewhat disgusted at not being consulted in the matter, we now find from a letter sent us by the promoters of the scheme that Newport has been consulted, and promises of support have been received from several shipowners and others in that town. Our information was derived from a letter written to a local paper by a Newport firm, and our note a reproduction in substance of that letter, which we are now told was inaccurate.

"JOURNAL OF THE SOCIETY OF TELEGRAPH ENGINEERS."—We have received the current number of this journal. It contains Mr. Willoughby Smith's paper on "Volta-Electric Induction;" Messrs. Trott and Kingsford's papers on "Submarine Cables," and a new grapnel therefor; Mr. J. E. H. Gordon's papers on "An Instrument for Measuring the Strength of the Magnetic Field," and "A Method of Calculating the Total Horse-power Expended in a Network of Conductors;" an original communication from Mr. J. Graves on "Hemp *versus* Iron-covered Cables;" and a number of abstracts from foreign *Transactions*, &c. We are glad to see the number of these abstracts increasing.

THE TELEPHONE IN BOSTON.—Just three days after the Boston Central Office was burned out and over 3,000 subscribers left without service, says the *Electrical Review* of New York, the exchange was completely rebuilt and the usual connections made. During this time fifty new office cables were run from the switches to the roof, every conductor (50in. each) tested and tagged, and connected each conductor with its respective line wire on the fixture. The water, moisture, and dirt were cleared out of forty sections of switch. All the telephones and transmitters connected with the switches were also cleaned and repaired, and, in fact, everything necessary for communication done as formerly.

LONG DISTANCE TELEPHONY.—Some very successful experiments in communicating over long distances by telephone have been made by the officials of the electric telegraph department at Port Elizabeth. The first experiment, says *The Colonies and India*, was made between Port Elizabeth and Graham's Town, when the sound was freely transmitted along the line, a lively conversation being carried on. Songs sung were also distinctly heard at the other end. The Fort Beaufort line was then connected, and an extension made *viâ* Humansdorp, giving a total length of communication of over 400 miles, through which the sound travelled with astonishing clearness. It is probable that an attempt will shortly be made to communicate with Cape Town by the telephone. If this can be done it will prove a great boon.

THE NEW ATLANTIC CABLES.—The ss. "Faraday," Messrs. Siemens Brothers' cable ship, sailed last week to lay the first portion of the Gordon-Mackay cable. Having had her propeller damaged by fouling with a chain, she was obliged to put into Queenstown Harbour, on Friday, February 1, for repairs. She has five hundred miles of cable on board, and will begin laying from the American coast. When in Queenstown the "Faraday" was boarded by reporters. One of them describes how the electricians on board keep up communication with one another through the cable, so as to be sure of its soundness. The apparatus for receiving these messages he describes as follows:—"The galvanometer has in it a small mirror, on which a stream of light is poured, and the needle which deflects its motion is magnified and reflected on a sheet of cardboard, and it is from this that the messages are read."

QUICK TELEPHONIC WORK.—A Birmingham correspondent sends us the following items of quick work:—On the 20th December last work was begun on the erection of sixty telephone lines for firms in Birmingham by the National Telephone Company, and they were all connected up and working through to the Central Exchange by the 4th inst., less than six weeks. The lines each average 620 yards in length, and deducting time lost by stoppages of different kinds, our correspondent says the work was really done in five weeks. The necessary standards and fixtures were erected in each case as well as the wires. In another case a firm in Wolverhampton gave an order on the 30th January at 5 p.m. for an exchange and private line, including two sets of instruments and three quarters of a mile of wire. Both lines were completed and working by 5:30 p.m. on the 31st January. The whole work was finished in nine hours by five men.

TELEPHONIC EXTENSION IN SCOTLAND.—On Monday last telephonic communication was established between the National Telephone Company's Central Office in Aberdeen and the Culter Paper Mills, at Culter, a distance of rather over eight miles. The line just completed is the longest that has yet been established in Aberdeen, the line next in length being that connected with Stoneywood Works, which measures 5 miles and 654 yards. To test the working of these two lines they were connected up through the exchange, and it was found that conversation could be carried on with

Digitized by Google

ease over the 13 and odd miles of wire. The work was carried out under the superintendence of Mr. J. D. Miller, manager of the Aberdeen Exchange. We may mention that the overhead wires in Aberdeen have been as far as possible carried at right angles across streets, instead of diagonally, as is so frequently the case in London and elsewhere. This minimises the risk of accidents to a great extent.

A Zinc-Lead Accumulator.—M. Regnier has constructed an accumulator in which the negative plate is composed of lead covered with electrolytically deposited zinc, the positive plate being an ordinary Planté electrode, with large surface. The latter is a long, thin plate of lead, on either side of which are two negative plates, formed of strips of riband lead, electro-zinced by electrolysis in an acid solution of sulphate of zinc contained in the glass jar forming the cell, and then amalgamated. The plates are supported by a wooden cover fitting on the top of the glass cell, and the plates are not allowed to touch the bottom by several centimetres, in order to avoid short circuits formed by pieces of lead oxide or reduced zinc. The following data relating to this battery have been made public:—E.M.F., 2·35 volts; average resistance, ·04 ohm; normal current on discharging, 5 to 7 amperes; charging current, 1 to 3 amperes; capacity of accumulation, after 100 hours of formation, 100,000 coulombs, after 500 hours of formation, 125,000 coulombs; surface of the positive plate, 60 square decimetres; surface of the negative plate, 5 square decimetres; weight of the positive plate, 2,800 kilog.; weight of the negative plate, ·650 kilog.; weight of the cell, 1·000 kilog.; weight of the liquid, 1·700 kilog.; weight of the cover ·200 kilog.; weight of the terminals, &c., ·250 kilog.; total weight, 7·200 kilog.

The Telegraph in the Brazilian Empire.—A correspondent, signing himself "Anglo-Brazilian," wrote as follows to the *Standard* of the 6th inst.:—"The Empire of Brazil is already overburdened by financial commitments; but, so far as their telegraphic administration is concerned, it is an error to suppose that an arrangement with the Western and Brazilian Company would result in any loss. The volume of traffic passing over both systems (of which the Western and Brazilian Company, since its reduction of rate, carries about 90 per cent.) is so great that an arrangement with that company would show a large reduction of expenses and a profit on the working on the part of the Government, in place of the annual and increasing deficit which is now shown by this department, apart from interest on capital expended. This annual loss cannot now fall far short of £150,000. Money literally wasted, and sufficient to pay interest on £3,000,000 of the Brazilian Debt. Apart from the question of justice to an undertaking which has strong claims on the Government, the Brazilian authorities would in absorbing the Western and Brazilian Company benefit their finances, and become the owners of the entire telegraphic system of the Empire, as is the case in other countries. The position is now being appreciated in Brazil, and if space would allow I would demonstrate, without fear of contradiction, that the saving referred to by the union of the two systems is not simply on paper, but is based upon careful calculations and a thorough knowledge of the position."

Electric Lights for Mines.—In a recent issue of the *Colliery Guardian* Mr. G. G. André speaks in the following terms of electric light for mines: "I have another word to say on the matter of electric safety lamps, on which I made some remarks a few weeks ago. All, so far as I have observed, who discuss the question in this country proceed on the assumption that the lamps are to be fed from wire leads, as in the case of lighting at surface. I think practical men are pretty well agreed that the lighting of fiery workings cannot be carried out in this way. Irrespective of the trouble attending the use of wire leads in underground workings, the dangers of rupture and 'short circuits' rob the system of the advantage which the lamp itself gives it. But to combat this system is to fight the wind. No one, so far at least as my observation has extended, is thinking of lighting in this way. Those who are occupied in this work of lighting fiery places provide means for generating the current within the lamp itself by some form of galvanic cell of either a primary or a secondary nature. And it was to those efforts that my recent remarks were directed. The problem is beset with difficulties, but there is good ground for hoping that a sufficiently practical solution will shortly be arrived at. The chief difficulty has been the want of hearty co-operation on the part of mining men." Perhaps those gentlemen who scoffed so heartily at the idea of electric lights for mines, at a recent meeting of the Chesterfield Mining Institute, will give some slight consideration to Mr. André's words.

Efficiency of Accumulators.—In *Wiedemann's Beiblätter*, Vol. VII., H. Aaron has an article on calculating the efficiency of accumulators, of which the following is an abstract:—The efficiency of accumulators can be calculated in four different ways: 1. There is the efficiency of charge, or the relation $\left(\frac{q}{Q} = n\right)$ of the quantity of electricity issuing on the discharge to that entering during the charge. If $c$ and C are the values of the variable currents in these two operations respectively, then $n = \int_o^t c\,dt \div \int_o^T C\,dt$, where $t$ and T are the periods of discharge and charge respectively. 2. The efficiency of chemical action, or the relation $N = \int_o^t e\,c\,dt \div \int_o^T E.C\,dt$, where $e$ and E are the values of the E.M.FF. at each moment of discharge and charge respectively. 3. The electrical efficiency K which $= \int_o^t (e\,c - c^2 r)\,dt + \int_o^T (EC - C^2R)\,dt$, where $r$ and R are the resistances of the battery during discharge and charge respectively at each moment, in which formula the loss due to heating of the battery is taken into consideration. 4. The efficiency of mechanical work $= a\,K$, where $a$ is a factor which is the relation of the useful part of the energy of the charging machines to the energy of the motor expended in putting them in motion. If E and $e$ are constant, then $N = \frac{e}{E} n$, and if they equal one another, then $n = N$. From the experiments of Hallwachs $N = \cdot 9\,n$ on the average, but important deviations from this rule occur, as when $N = \cdot 8\,n$, and other values.

The Conductivity of Saline Solutions.—At a meeting of the Paris Academy of Sciences, on the 21st ult., M. E. Bonty contributed a note on the above subject. He stated that the electric conductivity of salts dissolved in water varies with the degree of concentration in a very complex manner, and differs with different salts. We possess no general law or empirical formula in this respect capable of any extended use. It is conceived, *a priori*, that this conductivity depends at the same time on the chemical nature of the salt, the hydrates which it can form, and their stability. Experiment likewise has determined that it has relation to

Digitized by Google

some of the physical properties of the solution, particularly to its degree of viscosity. But the part played by each of these has not yet been determined. The conductivity of salts is connected with their chemical composition by very simple laws. Let $p$ be the weight of the salt contained in unit weight of the solution, $e$ the chemical equivalent, $c$ the conductivity of a liquid cylinder of length and section equal to unity. For each salt there is a value, $p$, of $p$, below which the conductivity varies proportionately to the weight of salt dissolved; if, therefore, we compare the conductivities of different salts, we find that they are in inverse ratio to the equivalent, and we can write $C = k\frac{p}{e}$. The co-efficient $k$ is the same for all neutral salts that the author has studied. Taking the formula $p = e$, that is, considering the solutions which contain, in the same volume, one equivalent of the different salts—that is, the same number of molecules—the conductivity $c$ is the same for all. The molecular conductivity of all neutral salts is the same.

The Electric Light in the House of Commons.—From the Easter recess to the close of the Session last autumn the libraries and dining rooms of the House of Commons were lighted by about 270 Edison incandescent lamps. The lighting having been entirely successful some extension of it was deemed desirable by the First Commissioner of Works, and accordingly additional plant has been recently laid down by the Edison and Swan Company and the total number of lamps is now increased to about 480. The machinery is fitted up in a portion of the basement of the house adjoining the boiler room, and consists of two $8\frac{1}{2}$in. by 10in. Armington and Sims horizontal high speed engines, running at about 300 revolutions per minute, the one engine driving two Edison 250-light dynamos, and the other two 150-light dynamos. The electrical arrangements admit of any circuit being operated by any dynamo, and as each pair of dynamos is run in multiple arc (that is, each dynamo of the pair performs half the work done by the two together), it will be seen that ample provision has been made against any failure of the light from accident to the engines or machines. The distribution of the lamps is as follows:—Dining rooms, libraries, &c., 276; under galleries in the house, pilaster lamps, 32; division lobbies, table lamps, 24; divisional lobbies, pendants, 32; divisional lobbies, staircases, 4; south entrance lobby and staircases, 13; north lobby, 8; ministerial rooms, lavatories, &c., 16; retiring rooms, &c., 40; reporters' rooms, 21; reading room, 12; total, 478 lamps. The existing gas fixtures have in several instances been utilised for the incandescent lamps by means of ornamental attachments in harmony with the character of the chandeliers. In other cases neat polished brass pendants, brackets, &c., fitted with opalescent shades have been provided. The wires are throughout entirely concealed from view, being either carried behind the panelling or encased in mouldings stained to the colour of the surrounding woodwork. The lamps are arranged on a considerable number of separate circuits, each capable of being lighted or extinguished by its proper switch. In a small apartment immediately under the floor of the House about 20 of these circuits converge on a switch-board, and can be controlled by the attendant who possesses the key to the switches. Each switch is surmounted by a double-pole safety fuse, and each circuit is lettered. In no part of the house will the electric light prove a greater boon than in the rooms set apart for the use of the gallery reporters, who have hitherto, owing to the contracted space they were crowded in, suffered from a highly vitiated atmosphere. The whole of the work in connection with the installation of the light has been carried out under the superintendence of Mr. T. O. Belshaw, of the Edison and Swan Company, Mr. Prim supervising the arrangements on behalf of the Office of Works.

An Exhibition of Electric Lighting.—A numerous company assembled on Tuesday and Thursday evenings at Mr. Brotherhood's premises in Belvedere-road, Lambeth, to witness an exhibition of electric lighting. The spacious shop was lighted on either side by Edison and Swan incandescent lamps to the number of about 300, which had been specially fitted up for the occasion by the Edison and Swan Company. A single Edison-Hopkinson dynamo was employed, driven direct by one of Brotherhood's newly designed engines. Various forms of fittings suitable for ship work were shown, which included the newest patterns specially designed by the company to give the best effect to the light and to guard against dirt, damp, and breakage. Outside, on the roof, were shown ships' dioptric lanterns provided by Messrs. Chance Brothers, and fitted with 100 candle-power lamps, which, whilst free from the disadvantageous glare accompanying an arc light, yield a light four times as great and far more distinctive and penetrating than can be obtained from the best oil lamp. Looking from the opposite side of the Thames, one could not help being struck with the brilliancy of these lights, as compared with the oil lamps placed alongside them. High up from the beams were suspended four inverted reflectors with a group of eight 50 candle-power lamps in each, a pattern of lantern which has been adopted by the Admiralty for deck lights, and which slung from the yard arm suffices to illuminate half the deck. Later on in the evening, the incandescent lamps having been extinguished, the whole of the current from the same dynamo was directed without further alteration to a large search light with projector, which was placed on the roof of the building overlooking the river. Its rays were directed on to the Houses of Parliament and surrounding objects with remarkable effect. They revealed all the details of the stonework with a distinctness never even seen in the brightest sunlight. As distinguished from his original engine, the novel features presented by Mr. Brotherhood's improved type consist in the adoption of piston valves and special arrangements for the effective distribution of the steam, allowing of bearings being fitted to each side of the crank, an economy of steam being obtained fully equal to that of any ordinary type of high speed engine, combined with durability and equable motion. The cylinders are 8in. diameter by 6in. stroke, and at 615 revolutions and 75lb. pressure, with a cut off of about $\frac{3}{10}$ths., 43 horse-power is obtained. The dynamo was connected direct by means of Mr. Brotherhood's new patent flexible coupling, which is likely to prove a most valuable means of getting over difficulties so often encountered through false alignment and back lash. It consists of a ring of leather, the outer periphery of which is held to one half of the coupling by a junk ring, the inner edge being similarly connected to the other half coupling, a radial distance between the two halves allowing of a considerable amount of flexibility. The dynamo, as before mentioned, is an Edison-Hopkinson with elliptical magnets, wound for 107 volts, and capable of maintaining 400 20 candle-power lamps. Notwithstanding the strain to which it was subjected when applied to the search light, no undue overheating was observable. We may remark also that circuits of 60 incandescent lamps and more were frequently cut out and put in again during the evening without appreciably affecting the other lamps or the speed of the dynamo.

## ELECTRO-CHEMISTRY.

### INORGANIC.

BY DR. G. GORE, F.R.S.

(CONTINUED FROM PAGE 247.)

**Separation of Boron.**—B. Atomic weight = 31. A triad cation. By contact of magnesium with boracic acid in a fused state, boron is set free (Phipson, *Proc. Roy. Soc.*, Vol. XIII., 1864, p. 217; also *Chemical News*, Vol. IX., p. 219.)

"Boron was first electro-chemically isolated by Sir H. Davy. He states that when boracic acid is exposed between two surfaces of platinum, receiving at the same time all the action of a current from 300 cells, an olive brown matter is formed upon the negative surface, gradually increasing in thickness, and finally becoming black. The isolated body is boron" (*Chemical News*, Vol. XII., p. 3).

**Electrolysis of Oxide and Fluoride of Boron.**—Burckhard states (*Chemical News*, Vol. XXI., p. 238) that pure boracic acid in a state of fusion is a non-conductor. I found that by electrolysing pure borofluoride of potasium in a fused state, with platinum electrodes and a separate current, boron was deposited, and combined with the cathode, rendering the latter rough and brittle.

**Separation of Silicon.**—Si. Atomic weight = 28. A tetrad cation. According to Golding Bird (*Phil. Trans. Roy. Soc.*, 1837, p. 37), silicon may be electro-deposited from a solution of its fluoride in alcohol. The kind of apparatus he employed was a combination of one voltaic cell in undivided circuit, with a "single cell apparatus," the silicon being deposited upon the negative platinum plate of the latter. I electrolysed in a platinum cup a fused mixture of 300 grains of 97·1 per cent. pure potassic carbonate (the 2·9 per cent. being water) and 442 grains of silico fluoride of potassium, by a current from ten Smee cells, a sheet platinum anode, and a platinum wire cathode. Gas arose from the cathode at first only; after that streams of black matter poured down from the cathode, and the latter acquired a blackish film, but subsequently alloyed with silicon, and fused on its surface.

**Separation of Hydride of Silicon.**—This compound is obtained, in admixture with much free hydrogen, when the current from 8 to 12 Bunsen elements is passed by means of an anode of aluminium containing silicon, into an aqueous solution of common salt. The aluminium dissolves as chloride setting free much gas, some of the bubbles of which inflame spontaneously in the air, emitting a white light, and differing finely divided silica. The compound appears to be due to a secondary action; a part of the nascent hydrogen, set free by union of aluminium with the oxygen of the water, unites with the silicon (Wöhler, and Buff, *Annales Chem et. Pharm.*, Vols. CII., CIII., CIV., and CXII.). It is not stated whether this compound would be formed by simple immersion without a separate current. I have observed that a lump of fused silicon, immersed in a mixture of pure hydrofluoric acid (strong) and nitric acid, evolves a spontaneously inflammable gas.

By electrolysis, silicic and boric anhydrides are separated from their concentrated solutions at the anode (C. Luckow, *Jour. Chem. Soc.*, Vol. XXXVIII., 1880, p. 283).

Becquerel has investigated the decomposition of silicates and other minerals by electro-capillary diffusion (*Comptes Rendus*, Vol. LXVII., p. 1081).

**Separation of Titanium.**—Ti. Atomic weight = 50. A cation. This element does not appear to have yet been electro-deposited, nor its compounds electrolysed. I observed that crystals of nitro-cyanide of titanium conducted freely a current from 60 Smee elements.

For the electrolytic analysis of zirconium, see A. Claessen, *Jour. Chem. Soc.*, Vol. XLII., 1882, p. 896.

**Separation of Sulphur.**—S. Atomic weight = 32. A dyad anion; sometimes also separated by secondary action at the cathode. Obtained by electrolysing, by means of a separate current and platinum electrodes, an aqueous solution of sulphide of potassium, hydrogen being simultaneously set free at the cathode (Faraday).

MM. Blas and Miest have shown that if in electrolysis we replace the anodes of metal by metallic sulphide ores compressed to hard plates, and use a suitable electrolyte, all the sulphur of the ore is separated at the anode and falls down, and the metal is deposited upon the cathode (*Chem. News*, Vol. XLVI., pp. 93 and 121; *The Electrician*, Vol. X., p. 388).

**Hydric Sulphide.**—$H_2S$. Molecular weight = 34. This substance when liquefied by great pressure does not appear to have been yet subjected to the action of an electric current. Its aqueous solution would no doubt yield sulphur at a platinum anode. When dilute sulphuric acid is electrolysed with a zinc anode and a charcoal cathode, hydric sulphide is evolved at the latter. (Highton *Chem. News*, Vol. XXVI., p. 117.)

**Electrolysis of Sulphur Dioxide.**—$SO_2$. Molecular weight = 64. This oxide, liquefied by pressure, does not transmit a current from 40 cells. An aqueous solution of the gas yields sulphur and hydrogen at the cathode by the passage of such a current. (De la Rive, Gmelin's "Handbook of Chemistry," Vol. II., p. 170.)

The electrolysis of its aqueous solution, $H_2SO_3$, is not simply a separation of the oxide into oxygen at the anode and sulphur at the cathode. According to A. Guerout (*Comptes Rendus*, Vol. LXXXV., p. 225), with a feeble current, $H_2SO_4$ is produced at the anode, and a yellow liquid at the cathode; with a stronger one sulphur also appears with the yellow liquid, and with a still stronger, sulphur alone is deposited at the cathode. Its electrolysis resembles that of a salt, the acid and oxygen being set free at the anode, and the hydrogen ($H_2$) appearing at the cathode, where it acts upon a fresh portion of the acid, and reduces it thus:—$H_2 + H_2SO_3 = H_2SO_2 + H_2O$. This agrees with the fact that hyposulphurous acid ($H_2O_2S$) and sulphur appear at the cathode, the sulphur being produced by the decomposition of that acid formed there in a concentrated state. (*Chem. News*, Vol. XXXVI., p. 90.)

Sulphurous acid in aqueous solution is decomposed by the current into sulphur and sulphide of hydrogen, and sulphites are gradually converted into sulphates. Thiosulphates are converted into their corresponding sulphates with separation of sulphur. The alkaline sulphides, according to their richness in sulphur, are decomposed with or without separation of sulphur, sulphates being formed. In the alkaline sulphates, and thiosulphates, in addition to sulphides, polythionates are always produced. (C. Luckow, *Jour. Chem. Soc.*, Vol. XXXVIII., 1880, p. 283.)

A copper zinc couple liberates sulphur from sulphurous acid, without producing sulphuretted hydrogen. (Gladstone and Tribe, *Jour. Chem. Soc.*, Vol. XXXIII., 1878, p. 307.)

**Electrolysis of Sulphuric Acid.**—$H_2SO_4$. Molecular weight = 98. Sulphuric anhydride ($SO_3$) is a non-conductor with a current from 14 Bunsen cells. Its solution in concentrated oil of vitriol is decomposed by a separate current with platinum electrodes into oxygen at the anode, and sulphur at the cathode. By varying the proportion of the two substances, part of the sulphur reduces the sulphuric acid to sulphurous anhydride, which is evolved at the cathode. (Geuther, *Ann. Chem. et Pharm.*, Vol. CIX., p. 130.)

By electrolysis, concentrated English sulphuric acid is decomposed with deposition of sulphur. (C. Luckow, *Jour. Chem. Soc.*, Vol. XXXVIII., 1880, p. 283.)

**Separation of Persulphuric Acid.**—$S_2O_7$. Berthelot divided two portions of diluted and chilled sulphuric acid by a porous partition, immersed stout platinum wire electrodes in the two portions, and passed a dense current from three very large Bunsen cells through the liquids, and thus obtained a mixture of dilute sulphuric acid, containing 88 to 123 grammes of $S_2O_7$ per litre. (*Comptes Rendus*, No. VII., February 16th, 1880. *Jour. Chem. Soc.*, Vol. XXXVIII., 1880, p. 607.) Liquid chloride of sulphur, and also carbonic bisulphide, are non-conductors.

Digitized by Google

**Separation of Selenium.**—Se. Atomic weight = 79·5. A cation; acts also as an anion. Very little investigation has yet been made of the electrolysis of compounds of this element. A mixture of aqueous hydrofluoric and selenic acids yielded much red selenium upon the cathode. During the electrolysis by a separate current of an aqueous solution of selenate of nickel, containing selenate of sodium and free selenic acid, I repeatedly observed an abundant deposit of bright red selenium upon a platinum cathode. The deposition was no doubt due to decomposition of the free acid, because it ceased on neutralising the acid with ammonia. According to L. Schicht (*Chemisches Centralblatt*, No. XXIV., 1880; also *Berg und Hüttenmannische Zeitung*, 1880), selenium is readily and completely reduced and thrown down by a feeble current from not more than two cells, both from acid and alkaline solutions. (*Chemical News*, Vol. XLI., p. 280, Vol. XLII., p. 331, and *English Mechanic*, Vol. XXXI., p. 540.)

**Separation of Tellurium.**—Te. Atomic weight = 129. A triad cation. Ritter, and subsequently Sir H. Davy, observed whilst electrolysing water with a tellurium cathode that the water around the cathode acquired a purple colour by dissolving telluride of hydrogen, and then precipitated a brown powder. Magnus showed that the brown powder was metallic tellurium set free by oxygen, which diffused from the anode, and decomposed the telluride. If the water is acid the telluride does not dissolve, but escapes as gas.

L. Schicht states (*Ibid*) that tellurium is readily and completely thrown down both from acid and alkaline solutions, but more readily than selenium. From an acid solution it is easily deposited with a blue black colour, and from alkaline ones it is separated in a very loose state at the anode with much evolution of gas, and that if much metal is present it floats as a light powder upon the liquid.

**Electrolysis of Telluric Fluoride and Chloride.**—I have electrolysed pure dilute hydrofluoric acid with an anode of pure tellurium and a current from a single Smee element. The action was very slow, and most excellent deposits of bright reguline metal of grey colour and bright crystalline structure were obtained. By electrolysing a pure solution of telluric chloride by means of a very feeble current and large electrodes of smooth platinum I obtained only a jet black deposit, chiefly of non-adherent metal.

For the electrolytic purification of tellurium, see Watts's "Dictionary of Chemistry," Vol. VIII., Part 2, p. 1895.

**Separation of Phosphorus.**—P. Atomic weight = 31. A triad element. Acts both as an anion and a cation. According to Burckhard (*Chemical News*, Vol. XXI., p. 238) fused pyrophosphate of sodium yields by electrolysis with a separate current phosphorus and oxygen at the anode, and soda at the cathode; if the anode is composed of platinum a phosphide of that metal is formed.

**Electrolysis of Oxides of Phosphorus.**—The electrolysis of concentrated phosphoric acid produces a metallic phosphide with the cathode when the latter is composed of copper or platinum. (H. Davy.)

By electrolysis with platinum electrodes, dilute solutions of phosphoric acid or phosphates undergo no change. (C. Luckow, *Jour. Chem. Soc.*, Vol. XXXVIII., 1880, p. 283.)

The electrolysis of phosphoric acid and solutions of its salts, with electrodes of wood charcoal, or retort carbon, produces phospho-mellogen, and with graphite electrodes phospho-graphitic acid. (Bartoli and Papasogli, *Jour. Chem. Soc.*, Vol. XLIV., 1883, p. 592; *Electrician*, Vol. XI., pp. 28 and 101.)

**Chlorides, Bromides, and Iodides of Phosphorus.**—These are non-conductors of a voltaic current.

**Separation of Arsenic.**—As. Atomic weight = 75. A triad cation. Easily separated by various electrolytic processes. Palladium charged with hydrogen reduces a solution of arsenious acid to metal without producing arsenide of hydrogen. (Gladstone and Tribe, *Jour. Chem. Soc.*, Vol. XXXIII., 1878, p. 308.) It is also separated. 1. By dissolving arsenious acid in warm dilute hydrochloric acid, and stirring the solution with a piece of clean copper the latter acquires a coating of arsensic; this is the well known "Reinsch's test" for the element. 2. By contact of zinc with platinum in solutions of arsenic the latter is deposited upon the platinum; and 3. By passing a separate current through a solution of arsenic in dilute hydrofluoric acid, by means of an anode of arsenic and a cathode of platinum, I have obtained a scaly deposit of the metal.

The electrolysis of arsenic acid, and solutions of its soluble salts with electrodes of wood charcoal, or gas carbon, yields mellogen free from arsenic. (Bartoli and Papasogli, *Jour. Chem. Soc.*, Vol. XLIV., 1883, p. 592; *Electrician*, Vol, XI., pp. 28 and 101.)

**Separation of Arsenide of Hydrogen.**—$AsH_3$. Molecular weight = 78. From acid solutions of arsenic, magnesium by simple immersion evolves this poisonous and inflammable compound. (Roussin, *Chem. News*, Vol. XIV., p. 27.) Marsh's test for arsenic consists in evolving this gas from an acid solution of arsenic by simple immersion of zinc in it. The same gas is evolved at a platinum cathode by the passage of a separate current through solutions of arsenic, when the current is sufficiently strong. A solid hydride of arsenic, supposed to have the composition $AsH_2$, is produced when water is electrolysed by a strong current, with metallic arsenic for the cathode. (Watts's "Dictionary of Chemistry," Vol. III., p. 181.)

**Terchloride of Arsenic.**—$AsCl_3$. Molecular weight = 181·5. This liquid is a non-conductor of a voltaic current, but the aqueous solution conducts readily and is decomposed.

For the electrolytic analysis of arsenic (see *Jour. Chem. Soc.*, Vol. XLII., 1882, p. 1320; also *Chem. News*, Vol. XLVI., p. 106.) And for the detection of arsenic in mineral waters by means of a voltaic couple of tin and gold, see J. Lefort, *Jour. Chem. Soc.*, Vol. XXXVIII., 1880, p. 510.)

(TO BE CONTINUED.)

---

## REPORT OF PROFESSOR CHARLES R. CROSS ON EXPERIMENTS WITH THE BRUSH STORAGE BATTERY.

A No. 3 20-light Brush storage battery of 24 cells was sent to me from the factory of the Brush Electric Company at Cleveland, and, together with the "manipulator" and a number of Swan incandescent lamps, was suitably installed in the laboratory of the Massachusetts Institute of Technology, Boston. The battery and lamps were set up and connected with the dynamo machine by Mr. Nicolaus, a gentleman detailed by the Brush Company for the purpose.

The battery was composed of four troughs, containing four cells each, two of three cells each, and two separate cells, this division allowing any necessary changes in the arrangement or number of the cells used to be made readily, and also allowing several spare cells to be used as desired. The weight of one of the single cells was 79·2lb., and that of the whole 24 cells was therefore something under 1,900lb, since the weight of the troughs of three or four cells is somewhat less in proportion than that of the single cell.

Three sets of Swan lamps of different resistance were furnished from the factory of the Brush-Swan Company, of which the set having the highest resistance gave the most satisfactory results in my preliminary experiments. As it seemed very desirable to reach a speedy decision regarding the work of the battery, this set of lamps was used in all the succeeding tests, without attempting to see what results would be reached with the lamps of lower resistance. This matter can very readily be tested, however, in any place where the battery and lamps are used. The battery was charged by the current furnished by a No. 3 Brush two-light dynamo machine, furnishing a current whose value was usually about nine amperes. One arc light was included in

Digitized by Google

the circuit with the battery and dynamo whenever the battery was charged.

Although this is perhaps a somewhat severe duty for a two-light machine to perform, there was no difficulty in keeping the arc light at what was, so far as ordinary observation could show, its normal brilliancy. During those operations of charging that were carried on in the night time, the arc light served to illuminate the room in which the engine and dynamo were placed. It was not considered necessary to measure the power consumed in running the dynamo, as this is well known. With a current of eight amperes this is stated in the Brush Company's circular to be one and three-fourths horse-power. With the nine ampere current used in my experiments the power would probably be a little under two horse-power. I found that with slight instructions as to the dynamo and lamp, an ordinary engineer could take the whole care of the charging of the battery, as the "manipulator" never failed to perform its proper function of automatically throwing the battery into or out of the circuit on starting or stopping the dynamo machine. That part of the "manipulator" which is designed to throw the battery out of circuit when charged was not used by me in my experiments, as with a two-light Brush machine of the pattern which I have, the throwing of the battery out of circuit by it would short-circuit the machine, and if through inadvertence of the attendant in charge this change was not noticed, the machine would be injured by the abnormally strong current that would be produced under these circumstances; with the larger Brush dynamos, such as would be used in practice for charging the batteries, a self-regulating device is provided by which the current given by the machine is rendered constant, whether the battery is in or out of the circuit. The meter connected with the manipulator was found, when the clock was properly regulated, to furnish a correct register of the time during which the current entered the battery in the process of charging.

Since the current is practically constant in strength, the amount of electricity entering the battery is known. From this, in connection with a knowledge of the variation in the electromotive force of the battery as its charge approaches completion, the actual electrical energy required to charge the battery can readily be found, if desired, once for all.

After the battery was set up it was put in proper condition for use by prolonged charging. The necessity for this arises from the chemical changes which take place in the battery plates, incident to drying and exposure to the air in transportation. These changes do not occur subsequently when the battery is left to itself, since the liquid which has been placed in cells covers the plates, and thus protects them from the oxidising effects of the air. Owing to an absolute want of knowledge as to the length of time necessary to put the cells in proper condition, a considerable time was spent before this was accomplished. The lamps used are intended to give their normal light when run with a battery or dynamo of 38 volts electromotive force. The resistance when run under these conditions, that is, when heated to their proper temperature, is about 38 ohms, and the current traversing each is approximately one ampere. Experiment showed that 21 cells of the battery furnished the proper electromotive force and current for the lamps, a smaller number giving too little light, while a larger number gave, together with an excessive brilliancy, a current so strong as to endanger the long life of the carbon filaments of the lamps, and also to shorten correspondingly the time during which the battery could keep the lamps at a proper degree of incandescence. This number of cells, twenty-one, was accordingly used in the tests.

The points which I have been especially requested to examine and report upon immediately are (1) what quantity of electricity is necessary to fully charge the Brush 20-light storage battery; and (2) when thus charged, for how long a time will it run twenty incandescent Swan lamps, each at a mean brilliancy of 16 candle-power? My attention has in this connection been called to the statements made in the "Circular to Agents," issued by the Brush Electric Company, so that the request made is virtually to verify those statements by an impartial and rigid examination. I have done so with the following results, which I can best explain in direct connection with the statements of the circular:—

(1). The figures given on page 1 of the circular are so related that a verification of one series is sufficient for all. The statement is there made that a current of eight amperes, as furnished by a No. 3 Brush 2-light machine, will charge two 40-light storage batteries of twenty to twenty-two cells each in twenty-four hours. The current being the same, eight amperes, it would also take the same time to charge one 40-light battery (as the batteries are placed in series), and one-half the time, or twelve hours, to charge a 20-light battery, as the plates of the latter are only half as large as those of the former, and there is only half the work to be done within the battery to charge it. A current of different strength will charge the battery in a proportional time, since the time required to charge it depends only upon the actual quantity of electricity passing through it. Where no regulating device is used with the dynamo, the current in practice, and especially with a small machine, varies slightly in strength during the time of charging, partly from accidental causes, partly from the rise in electromotive force of the battery itself as the charge approaches completion. Thence in any test the actual amount of electricity entering the battery during the whole operation of charging must be ascertained.

I have paid especial attention to the charging of the battery in two sets of experiments. Until I had learned from experience to know from the indications of my electrical instruments when the battery was properly charged there was no certain means of determining this. So that in the first of the experiments now under consideration I prolonged the duration of the charging current somewhat longer than were necessary. In this case the charging current was continued for 10 hours 57 minutes, its average value being slightly over 9·2 amperes, and the total amount of electricity was 100·5 *ampere hours*, the ampere hour being the amount of electricity furnished by a currrent of one ampere during one hour. Were the current strength to have been eight amperes only, this would imply a duration of 12·58 hours (12 hours 34 minutes). From a comparison of the readings of my instruments in this case with their readings in later experiments I am led to conclude that the battery was really charged about 20 minutes before I stopped the charging current. This would reduce the value of the charge to 9·6 ampere hours, which with a current of eight amperes would require 12·11 hours, or 12 hours 7 minutes, to complete the charging.

In the second case the charging current was continued for 10 hours 15 minutes, and the amount of electricity was 94·7 ampere hours. This would require a duration of 11·8 hours, or 11 hours 48 minutes, with a current of eight amperes. In both these experiments the battery was found to be fully charged by the succeeding tests with incandescent lamps, as well as by the electrical measurements made.

The circular considers a current of eight amperes continued for 12 hours, or 96 ampere hours, to be neccessary for complete charging.

(2) The ability of the battery to furnish the necessary current for the incandescent lamps was tested by discharging it through a set of Swan incandescent lamps, usually 20 in number, noting the time during which these furnished a proper light, and measuring from time to time the candle-power of the lamps, as well as keeping a record of the variations in the current and electromotive force of the battery. In order to ascertain the average value of the light furnished by the lamps one of these was mounted in a dark room at one end of the bar of a Bunsen photometer, with a standard candle at the opposite end of the bar, and after applying the usual corrections to the readings taken the actual candle-power measured at any particular time was found.

From the various measurements made at different times during the time of discharge the average candle-power for that time was determined.

The particular lamp used was changed from time to time to make sure that the illuminating power of the different

Digitized by Google

lamps was substantially the same, which was found to be the case.

It ought to be remarked that many lights, both incandescent lamps and gas lights which are considered to be of sixteen-candle power, will really fall short of this value if actually measured. In four tests I reached the following results, the lamps (twenty) being in each case run for four hours, and the average candle-power during that time being as follows:—

| | |
|---|---|
| 1st test | 16·6 candle-power |
| 2nd test | 16·0* |
| 3rd test | 16·2* |
| 4th test | 17·8 |

A fifth test was also made, in which the actual photometric measurements were somewhat unsatisfactory on account of some difficulties with the apparatus, but in which the electrical variations were almost identical with those of the fourth test, and hence the candle-power of the lights must have been the same. The numbers marked with an * are those given by the tests following the charges of 10 hours 57 minutes and 10 hours 15 minutes, which I have particularly discussed. It appears that even in the least favourable case the lamp can be run four hours at an average candle-power of 16.

The average candle-power of the lamps during the first three hours of the tests was as follows:—

| | |
|---|---|
| (1) | 18·1 |
| (2) | 17·2* |
| (3) | 17·4* |
| (4) | 19·1 |

The candle-power was at 16 after the following times from beginning:—(1) two and one-fourth hours, (2) one and three-fourths hours, (3) two and one-fourth hours, (4) three hours.

I think that with more extended experiments it would be possible to produce Swan lamps which would give even still more satisfactory results when run in connection with the battery than those employed in my experiments. A most interesting and satisfactory test was made as to the time during which the battery would keep a smaller number of lamps than 20 up to their normal brilliancy. The battery was charged as usual, and discharged through 10 incandescent lamps, the same measurements being made as in previous tests. At the end of 10 hours of continuous running, the light of the lamps being still above 12 candle-power each, the experiment was terminated. The average candle-power during those 10 hours was 18·3, and the brilliancy was above 16 candle-power until about eight and one-half hours from the beginning. The average candle-power during the first nine hours was 18·8. This result is particularly interesting, as it shows the action of the battery when used as it would be in cases where only a portion of the maximum possible number of lamps are generally used at any one time.

Besides the foregoing matters there is another important and evident peculiarity of the Brush storage battery that demands notice. It is exceedingly important that the electromotive force of the battery shall diminish as slightly as possible during the whole practicable run, and that it should fall off notably only at the end of that time. Any decrease in the electromotive force causes a diminution in the current, and hence in the brilliancy of the lamps, both because of the smaller force urging the current through the circuit and because of the increased resistance of the lamps when their temperature falls with the primary diminution of current due to a lessened electromotive force. Thus a falling off in the electromotive force of from three to five volts, with an initial electromotive force of 38 volts, will reduce the brightness of the lamps to a point considerably below their average value, the brilliancy falling to 12 or even 10 candle-power. In the Brush battery this falling off occurs chiefly or often almost entirely towards the end of the operation. Thus, considering one experience which I take at random from my notes, but which is typical of all, the electromotive force of the battery of 21 cells at the beginning of the discharge was 37·6 volts; at the end of one hour 12 minutes this remained unchanged, 17 minutes later a diminution of two-tenths of a volt had occurred, in 49 minutes more a further diminution of two-tenths volts took place, in the next 11 minutes the electromotive force fell two-tenths more, and at the expiration of three hours from the beginning the electromotive force had diminished but nine-tenths of a volt. During the next and last hour of the run the falling off was more rapid, being for this time two volts, or more than twice as great as during the first three hours. This is also clearly seen in the run of 10 hours with 10 lamps, in which no perceptible falling off occurred during the first two and three-fourths hours, and during the first five hours the falling off was but one and one-half volt. The total falling off during the 10 hours' run was under four and one-half volts, of which about two and one-half occurred during the last two hours, and two during the last hour. This remarkable constancy in the electromotive force during the period of discharge is a most valuable feature of the Brush battery. With a somewhat more complete "forming" of the battery, giving a thicker layer of the lead oxide, this constancy, as well as the average candle-power during the four hours' run, could doubtless be increased.

I also desire to call attention to the great efficiency of the Swan incandescent lamps used by me. I find that, using 21 cells of the battery with an electromotive force of 37·6 volts, a current of 19·5 amperes was sufficient to cause 20 lamps to glow with a brilliancy of 17 candle-power each.

The energy expended in doing any electrical work is found by multiplying the electromotive force expressed in volts by the current expressed in amperes, which gives the energy expended in each second in volt-amperes or watts. This product divided by 745 gives the electrical energy in horse-power—what is called the electrical horse-power. One electrical horse-power is the amount of electrical energy that would be produced by a dynamo machine which was absolutely perfect, and in which there were no losses of energy, by friction or otherwise, by the expenditure of one mechanical horse-power.

The efficiency of such a dynamo would be 1. The efficiency of the Brush 16-light dynamo is $\frac{82}{100}$ths. With an electromotive force of 37·6 volts and a current of 19·5 amperes the energy expended in the lamps will be 733 watts per second, the leading wires used by me being so short and of such large section that their resistance need not be considered. An electrical horse-power is 745 watts per second, so that it appears that the efficiency of the Swan lamp is such that 20 lamps per electrical horse-power and giving a united light of 340 candle-power can be furnished by the expenditure of less than one electrical horse-power.

Another valuable peculiarity of the Swan lamp deserves mention. The peculiar shape of the carbon filament is such that the illumination is practically equal in all directions, which is not generally the case with incandescent lamps. I am unable at this time to insert all the results of my tests, which, indeed, are not quite completed. I have been obliged to draw up this report in great haste, in order to secure its reception at the time assigned, and have had to leave a number of interesting calculations incomplete. But the results relating to those points to which I was especially asked to direct my attention will, I think, be clearly understood from what I have written.

## MEETING OF THE SOCIETY OF TELEGRAPH ENGINEERS AND OF ELECTRICIANS.

At the meeting of this society, on Thursday, 31st ult., Professor Adams in the chair, the secretary announced that Lady Siemens had presented to its library a large number of volumes belonging to her ladyship's late husband, all of which would prove a valuable addition to the society's collection. An appropriate resolution, thanking Lady Siemens for the donation, was passed by the meeting.

Mr. EDWARD BRIGHT then read a paper "On a System of Electric Fire Alarms," relating chiefly to the work recently carried out in various parts of London electrically connecting

Digitized by Google

the district fire brigade offices with alarm pillar posts at selected spots in the public streets. Referring, first, to the earlier introduction of electrical fire alarms in the cities of the United States and on the Continent of Europe, Mr. Bright considered that most of the appliances in use there, especially those operated by clockwork, were too costly, and very liable to get out of order through exposure and rust. The system which had found favour with the Metropolitan Board of Works, adopted by Captain Shaw, and carried out by Her Majesty's Post Office Telegraph Department, was based on the introduction of a few yards of resistance wire into a circuit of known resistance, a principle patented by his brother, Sir Charles Bright, in 1852. It was devised for the purpose of discovering the locality of a fault by balancing on a differentially wound galvanometer the faulty line with an artificial line whose resistance could be varied and measured at will by means of a box of resistance coils. This method was described at length in Dr. Lardner's "Museum of Science," page 76, as long ago as 1854. An adaptation of the principle involved in Sir Charles Bright's method is what has now been applied to the signalling of fire alarms in the metropolis. A circuit is formed surrounding a given brigade district, and at suitable intervals the wire is brought up into an alarm post, at the dial of which is placed a small coil of known resistance different from any other coil in the circuit. Normally the line is invariable; but directly the signal is given by means of the handle in the post, the coil peculiar to that post is introduced into the circuit, the balance of the line is disturbed, a bell is rung at the station, and the galvanometer is deflected. The officer in attendance at once ascertains at which of the posts the signal has been given, by means of an indicator consisting of resistance coils corresponding to those on the circuit, the balance being restored to zero directly the indicator handle comes in contact with the twin coil, the locality of the fire being thus promptly ascertained. Captain Shaw has preferred to use constant currents on the line, so that any fault or accidental short circuiting would immediately betray itself on the galvanometer at the station, and matters are so arranged that this deflection would be in a direction opposite to that of the ordinary alarm signal. The receiving station acknowledges an alarm signal by a return current, which moves a red disc at the sending post. Almost all the signals are given by policemen, who are provided with keys and instructed how to use the alarum; but the glass face of the dial can be broken by anybody, and the general public as well as the police can give the alarm with perfect certainty of its being understood. By making the several resistances at the indicator and posts so as never to equal any two or more coils of the series, provision is made for the possible contingency of more than one signal being sent simultaneously. In practice a difference of five per cent. between the resistances of the several coils is found sufficient. These posts were introduced first in 1880, fifteen of them being tried experimentally. During the first ten months of their existence there were 50 alarm calls. Since then some twenty districts have been provided in various parts of London, extending from Bow to Knightsbridge, and from Lambeth to Stoke Newington. With the 21 fire stations there are at the present moment 140 call points, comprising 82 miles of wire, each station being of course in telegraphic communication with the central brigade. Referring to the opposition of certain suburban vestries to the erection of overhead wires for fire brigade purposes, Mr. Bright remarked that during his 30 years' telegraphic experience he had never heard of a case of injury from such wires along high roads, and the cost of putting them underground would be ten times greater. The late gales had done enormous damage, but it seemed to have left the overhouse-top wires intact.

Mr. Bright then directed attention to self-acting appliances for indoor use. They have been introduced with useful results in some private establishments, but had received no public recognition at present, even the insurance companies offering them but slight encouragement, in which respect they differed from the insurance companies in the United States, who had reduced their premiums where efficient self-acting heat indicators had been fitted up. The result of his past experience had induced him to adopt a bi-metallic spring as the surest means of indicating a rise of temperature. The action of such springs was illustrated by the lecturer, a slight rise above the highest normal temperature causing the spring to expand and make contact so as to ring the alarm bell in a distant bed room or other convenient place. The particular room affected was indicated by appliances exactly similar to those of the street alarm post, a resistance coil encased in a small wood box being fastened to, or built in, the structure. Its introduction into the circuit by the expanded spring making contact would be localised in the manner described for the fire station office. The ceiling was the proper place to fix the spring—say, in the cornice of the room—heat generated below being quickly accumulated in the upper region. Where electrical bells are already fixed the additional cost would be a mere trifle, and he had no hesitation in saying that in numbers of instances the adoption of these indicators of the first outbreak of a fire ought to be made compulsory, with a view to the saving of life as well as of property. He mentioned a singular occurrence in New York illustrating the value of this mode of giving the alarm. The engine station received a signal indicating fire on the fourth floor of a certain hotel. The engine arrived on the spot, but the men were refused admittance, as "there was no fire." Sure of their warning, however, the brigade forced their way to the floor indicated, and there of course found the fire, which had broken out and made some progress unknown to the occupants below. The proportion of serious fires in that city had been reduced, where self-acting alarms were used, from 20 per cent. to 5 per cent.; and he believed that a similar reduction in the amount of damage done in London would be effected by the general adoption of the system he had placed before the meeting. That system had been awarded the gold medal, both at Paris and at London, and he confidently recommended it as being cheaper, simpler, and more trustworthy than any other system he was acquainted with. In answer to Professor AYRTON, Mr. Bright stated that the breaking of the glasses and giving of false alarms by mischievous persons had ceased with the infliction of condign punishment by the magistrates on the offenders. Mr. SPAGNIOLLETTI and Mr. TREUENFELD also made some remarks upon the paper, both of whom were favourable to a more universal adoption of electrical fire alarms. Specimens of the various apparatus referred to amply illustrated Mr. Bright's paper. The usual vote of thanks closed the proceedings.

## A HISTORY OF ELECTRIC TELEGRAPHY TO THE YEAR 1837.

BY J. J. FAHIE, MEMB. SOC. TEL. ENGS. AND ELECS.*

NOTE.—Being anxious to make his History as complete as possible, th Author will be grateful to his readers for any information, no matter how small, in relation to the subjects treated of in these pages.

(CONTINUED FROM PAGE 261.)

### CHAPTER VII.

### TELEGRAPHS BASED ON ELECTRO-MAGNETISM AND MAGNETO-ELECTRICITY.

"The invention all admired; and each how he
To be the inventor missed;—so easy seemed
Once found, which yet unfound most would have thought
Impossible."—Milton's "Paradise Lost," book vi.

The signal-indicating part of the single-needle telegraph consisted of an ordinary Schweigger galvanometer. The needle was suspended horizontally by a silken thread, to which was attached, parallel to the needle, a little disc of paper, painted black on one side, and white on the other. By the deflection of the needle to the right, or to the left, according to the direction in which the current moved in the coil, either face of the disc could be shown at pleasure, and two primary signals could be thus obtained, whose repetitions variously combined would represent the twenty-six letters of the alphabet, the ten ciphers, and four conventional signs.†

In order to prevent the prolonged or violent swinging of the needle after each deflection, he fixed to the lower extremity of the axle a thin platinum plate, or scoop, which, dipping into mercury placed beneath, deadened the motions, changing what might otherwise be prolonged oscillations into *dead-beat* movements—a method since adopted in a modified form in some of Sir William Thomson's mirror galvanometers.

As a means of attracting attention, Schilling added a contrivance, the idea of which he clearly borrowed from Sömmerring's alarum. It differed from the instrument that we have been describing only in that the rod whence the needle was suspended was made of rigid metal (wire) and carried a horizontal arm, which, when the needle was deflected, struck a finely balanced lever, and caused a leaden ball resting upon it to fall upon another lever, and so release the detent of an ordinary clockwork alarum.

---

* The author reserves all rights of translation.

† The bi-signal alphabet is popularly supposed to have come into existence with the Morse telegraph, but, in reality, its invention is almost as old as the hills. It was constantly employed in all kinds of semaphoric, luminous, and acoustic signalling from the days of the Greeks and Romans down to our own time. Lord Bacon gives an example in the sixth book of his *Advancement and Proficience of Learning*, published in 1605; and a still better one will be found in *Cryptographia Frederici* (p. 234), published in 1685.

REESE LIBRARY OF THE UNIVERSITY OF CALIFORNIA

At first the currents were transmitted by touching the ends of the line wires (outgoing and returning) direct to the poles of the battery in one way or another, according to the direction in which the currents were required to flow through the coil. But soon this primitive arrangement was superseded by a simple commutator, consisting of (1) a wooden board having four small holes arranged in a square and filled with mercury, into which dipped severally the terminal wires of the battery and the ends of the line wire; and (2) another similar board provided with a handle on one side and two metallic strips on the other, the ends of which were turned at right angles to the face of the board. They thus formed bridges which were adjusted to dip into the holes of the first board and so establish connection in one sense or another between the poles of the battery and the ends of the line. As a guide to the operator the top of the second board was painted black and white.

These instruments were placed on view by the Russian Government at the Paris Electrical Exhibition of 1881, together with a model of Schilling's six-needle telegraph. We translate the following account of this instrument from *La Lumière Electrique*, for March 17, 1883:—

"This apparatus;" says the official (Russian) description of it, "consists of six multiplier coils, each inclosing a magnetic needle, suspended by a silken thread from a copper support. A little above each needle is placed the paper disc, painted black on one side, and white on the other, as in the one-needle telegraph.

"The sending arrangement consists of a key-board like that of a pianoforte, having sixteen keys, in pairs of one black and one white. Each key, on being depressed, closes the circuit of a galvanic battery, its poles being connected to the lower contacts of the black and white keys respectively. Thus, for example, the negative pole may be connected to all the black keys, and the positive pole to all the white ones. The first six pairs of keys are joined to the six line wires (of copper), which are connected at the distant station to the six multiplier-coils; the seventh pair serves to work the alarum through its own line wire; and the eighth and last pair is joined to the return wire."*

The official account from which we are quoting is very obscurely written, so that it is impossible to gather in what way Schilling proposed to work this telegraph. It would seem that he wished to show from one to six signals at a time, sometimes black, sometimes white, and sometimes both combined; but he could not effect the latter had he employed only one battery, as the account we are following would have us believe. He must, therefore, have used two separate batteries, and granting this, it is easy to see the immense number of permutations and combinations of which his apparatus was susceptible.

In 1830, Schilling set out for a voyage in China, and took with him a small model of his (? single-needle) telegraph, with whose performances he astonished the natives wherever he went. He returned to Europe in March, 1832, and again occupied himself with telegraphic experiments, and hence, possibly, the date, 1832, which many writers assign to his inventions.†

In May, 1835, he started for a tour in southern and western Europe, taking with him a working model of his one-needle telegraph. At Vienna, he engaged in a series of experiments upon it in conjuction with Baron Jacquin and Professor A. Von Ettingshausen. Amongst others they tried the comparative merits of leading the wires over the roofs of the houses, and burying them in the earth. The result was, as may be supposed, in favour of the former plan, for, owing to the defective insulation afforded by a thin coating of india-rubber and varnish, the earth in the latter case conducted the current from one wire to the other, which lay parallel to it, and at a little distance.‡

In September, 1835, he attended the meeting of German naturalists at Bonn, and there, on the 23rd instant, exhibited his apparatus before the Section of Natural Philosophy and Chemistry, over which Professor Muncke, of Heidelberg, presided. Muncke was so pleased with its performance that he had a model made for exhibition at his own lectures at Heidelberg; and other members of the Congress took away with them to their respective homes such wonderful accounts of its action that Schilling's telegraph was henceforth an object of great curiosity, and became a stock subject for popular lectures, and for articles in all the scientific papers of the period.

Dr. Hamel tells us* that, on his return home from Germany in 1836, Schilling received two letters urging him to bring his inventions to England, but he declined the suggestion, saying that he preferred to try to introduce them first in his own country. He was soon after honoured by a visit from the Emperor Nicholas, who witnessed with the greatest interest the performances of the telegraph "through a great length of wire," and ended by expressing the desire of having it established between St. Petersburg and Peterhoff. "Of all the high dignitaries," says Jacobi, "who surrounded him, His Majesty was the only one who foresaw the future of what was then looked on merely as a toy."†

As was the custom in such cases, a commission of inquiry was appointed, which consisted of Lieut.-General Shubert, Adjutant-General Count Klein-Michel, and Flugel-Adjutants Heyden and Treskine, with Prince Alexander Menshikoff as president. Schilling, in due course, submitted his plans, and gave the commissioners a choice of two modes of effecting the communication—(1) either the wires should be covered with silk and varnished, then bound together, tarred, and deposited along the bottom of the Gulf of Finland, or (2) "foreseeing the difficulties of such a plan, they were to be suspended on posts erected along the Peterhoff Road."‡

An experimental telegraph was set up at the Admiralty, the line consisting partly of overground, and partly of "cable" which was submerged in the canal. The ends of the line, with the appropriate instruments, were placed at a great distance apart, one being at the window of Prince Menshikoff's study, in the N.W. corner of the building, and the other in a room near the great entrance of "the building office."

The results appear to have been eminently successful, for, in due course, Prince Menshikoff presented to the Emperor a most favourable report, upon the strength of which an Imperial decree was issued (in May, 1837), ordaining the establishment of a telegraph to connect Cronstadt with the capital by means of a "cable," laid along the bottom of the Gulf of Finland. But Schilling died on the 6th of August, 1837, and he and his country missed the glory of establishing not only the first really practicable telegraph, but also the first submarine line.§

### 1833—8.—Gauss and Weber's Telegraph.

In this year Messrs. Gauss and Weber constructed an apparatus at Gottingen, which, although at first intended for purely scientific purposes, soon came to be employed as a means of ordinary correspondence as well. The telegraph, as we must call it, contrived by these well-known physicists is remarkable for three reasons—1st, as being the first in which magneto-electricity was used; 2nd, for the ingenious, yet simple, method of increasing the deviations of the signalling needle—a plan which was long afterwards adopted by Sir William Thomson in his beautiful mirror galvanometers;|| and last, though not least, for having

The line, consisting of two copper wires, main and return, was carried upon posts over the houses, and extended from the

* A short length of the original wires was shown in connection with the apparatus at the Paris Exhibition. There were eight copper wires, each separately insulated by a coating of resin, and all afterwards made up into a cable and bound with hemp also soaked in resin.

† Besides this error in date, it is often stated that Schilling employed *vertical* needles, that there were thirty-six of them, enclosed in as many multiplier coils! and that the line wires (? thirty-six also) were of *platinum!!* insulated with silk. All these mistakes are contained in one short paragraph, which originally appeared in the *Journal des Travaux de l'Académie de l'Industrie Française*, for March, 1839, p. 43, and which has since been copied unquestioningly into nearly every history of the telegraph that we have seen.

‡ These experiments are always described as if they had reference to an entirely new system of telegraph, the invention of Jacquin and Ettingshausen (see Dr. Hamel's *Historical Account*, &c., p. 60, Cooke's reprint). Andreas von Ettingshausen, a physicist of European fame, died at Vienna, May 25, 1878, aged eighty-two years.

* In his lecture on *The Telegraph and Baron Paul Schilling*, before the Imperial Academy of Sciences, St. Petersburg.

† Du Moncel's *Traité Théorique et Pratique de Télégraphie Electrique*, Paris, 1864, p. 217. Yet Russia was one of the last countries to adopt, generally, the electric telegraph. Why? "Because the Emperor Nicholas saw in it only an instrument of subversion, and by a *ukase* it was, during his reign, absolutely prohibited to give the public any information relative to electric telegraph apparatus, a prohibition which extended even to the translation of the notices respecting it, which, at this time, were appearing in the European journals" (Colonel Komaroff's *La Presse Scientifique des Deux Mondes* as quoted in the *Annales Télégraphiques*, for November-December, 1861, p. 670).

‡ Du Moncel, p. 217. Jacobi, whom Du Moncel is quoting, says:—"The latter proposition was received by the Commission with shouts of derision, one of the members saying in my presence, 'Your proposition is foolish, your wires in the air are truly ridiculous.'" We wonder what he would say, could he take a walk through some of our London streets, where alas! this *folly* has attained to *ridiculously* gigantic proportions.

§ Of course a wire insulated with (1) a thin coating of india-rubber and varnish, as in the Neva and Seine experiments of 1812—14; or (2) with resin, and hemp saturated with resin, as in the "cable" shown at the Paris Exhibition of 1881; or (3) with silk varnished and tarred, as just mentioned, would not last long, but necessity is the mother of invention, and practice makes perfect. The cable laid from Dover to Calais in 1850 was only a little less crude.

|| As early as 1826 Poggendorff applied a mirror to the magnetic needle for accurately determining minute variations in its horizontal declination. had an *actual* existence for several years, during which it rendered most excellent service.

Digitized by Google

Physical Cabinet to the Observatory; whence, in 1834, it was continued to the Magnetic Observatory of Professor Weber—a distance altogether of one mile and a quarter English. An ordinary voltaic pair was employed for generating the current until 1835, when it was replaced by a magneto-electric machine made by Steinheil of Munich.*

This instrument, called the *Inductor*, consisted of a compound two-bar magnet A, Fig. 1, weighing seventy-five pounds, fixed vertically on a stool; a wooden bobbin B, supplied with a handle L, and wound with 3,500 turns (and later with 7,000 turns) of insulated copper wire (No. 14, silvered), rested on the stool and encircled the magnet, as shown in the figure. On lifting the bobbin by depressing the handle, a momentary current would be induced in the coil in one direction, and on lowering it again to its position of rest another momentary current would be induced in the opposite direction. The ends of the coil B, were connected through a commutator to the line wires, and the distant ends of these were similarly joined to the ends of the coil of the receiver.

The receiver, shown in Fig. 2, consisted of a large copper frame, B, B,† upon which was wound 8,000ft. of insulated copper wire, like that of the inductor. A permanent magnet A, 18in. long and 3″ × 5″ transverse section, and weighing one hundred pounds, was suspended, in the interior of the coil by a number of untwisted silk fibres. To enable the observer to read off with care the minute deviations of the magnet, a small mirror M, was affixed to the supporting shaft, and in this was seen, through a telescope, at ten or twelve feet distance, the reflection of a scale placed above it. Notwithstanding the weight of the magnet, its movements were thus made beautifully energetic and distinct, a very small force, such as that supplied from a single cell, causing a deviation of over a thousand divisions of the scale.

The commutator, by means of which the electric currents were directed through the line wires in one sense or another, was similar to that of Schilling, being simply an arrangement for bringing two points alternately in communication with two others.

The *modus operandi* was as follows:—On lifting up the coil B (Fig. 1), by depressing the handle L, to the position shown by the dotted lines, a current was induced in the wire encircling them. This current passed by the commutator, through one of the line wires and the multiplier B B, of the receiving station, deflecting the magnet for an instant in one direction, and returned by the other wire over the commutator. When it was wished to deflect the needle of the receiving instrument in the opposite direction, this was attained by simply lowering the coil B again to its original place, and the observer at the receiving station read off one deflection to the right for instance, and one to the left. But, in constructing a code of signals, it was necessary that two or more deflections to the right or left should frequently follow each other. This was done by means of the commutator. Thus, on lifting the coil, if we suppose a deflection of the magnet was produced to the right, by reversing the commutator and then lowering the coil again, another deflection in the same direction would be observed. To produce a third deflection in the same direction it would be necessary, evidently, to reverse the commutator again before raising up the inductor. After this fashion Gauss and Weber were enabled, by combining the deflections to the right and to the left, to form the alphabet and numerals, with a maximum of four elementary signals. Various lengths of the pauses between the signals indicated the conclusion of words and sentences.

In 1835, an alarum was added, which, according to some accounts, consisted in giving to the magnet A (Fig. 2), a more than ordinary deviation, and so making it strike a bell; while, according to others, it was very similar to that of Schilling, the magnet, when largely deflected, upsetting a delicately-poised lever in train with the detent of an ordinary clockwork alarum.

Gauss and Weber's apparatus was in daily use for telegraphic and astronomical purposes down to the year 1838.

(TO BE CONTINUED.)

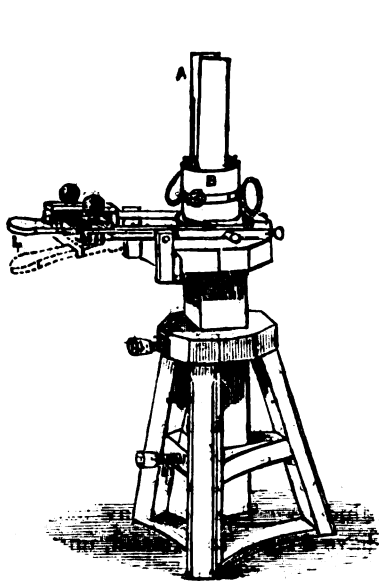

FIG. 1.—The Inductor of Gauss and Weber's Telegraph.

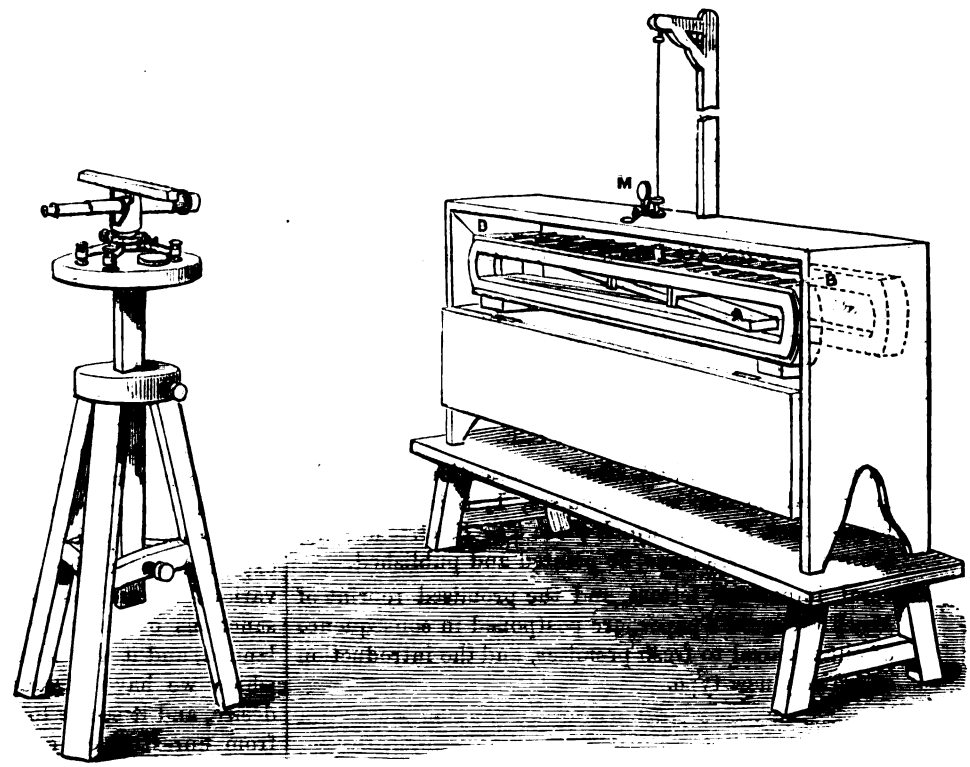

FIG. 2.—The Receiver of Gauss and Weber's Telegraph.

* In our account of Gauss and Weber's telegraph, we follow Sabine's "History and Progress of the Electric Telegraph," London, 1869, 2nd edit. pp. 33—8; and *La Lumière Electrique*, for March 17, 1883, p. 334. See also *Pogg. Ann.*, XXXII., 588; and *Dingler's Journal*, LV. 394.

† The copper frame, which Gauss called *the damper*, was necessary in order to prevent the great number of oscillations which the magnet would have made across the meridian had no such check been introduced. The checking action of masses of metal, and indeed of any other solid or liquid substance, in the vicinity of an oscillating magnet was discovered by Arago, in 1824. Sir William Snow Harris found that the oscillations of a freely suspended magnetic needle were reduced, from 420 without a damper, to 14 with a damper. In the present case the great mass of the magnet and the minuteness of the deviation must have aided materially in bringing it quickly to a state of rest.

## *ANSWERS TO CORRESPONDENTS.*

D. AND R.—TRAIN LIGHTING.—*Primary batteries are, we believe, used on the South Eastern Railway. On the District Railway a dynamo, fitted up with engine, &c., complete, in a van, is being used.*

## IMPORTANT NOTICE.

*** On and after the 8th inst. all communications should be addressed to our new premises, 1, Salisbury-court, Fleet-street, E.C., at which place *The Electrician* will, after next week's issue, be printed and published.

Several important letters, and the promised reprint of Mr. FitzGerald's paper, are postponed in consequence of our removal to fresh premises, and the introduction of entirely new type.

## THE EASTERN TELEGRAPH.

The announcement that Suakim has been included in the chain of communication uniting Great Britain with her Eastern dependencies again reminds us of the services rendered to this country during the past two years by the Eastern Telegraph Company. Whatever its local importance, Suakim was practically unknown to most Englishmen until the other day it suddenly sprung into notoriety as the base of impending military operations in the Soudan; and no sooner did this occur than news arrived that the Eastern Telegraph Company were about to connect that place by telegraph with their Red Sea cable. There has been some delay, on which we shall have to comment presently, but this was through no fault of the company, and communication is now established, not only with the chief seaport of the Soudan, but with Jeddah, on the Arabian shore opposite.

The effect of this extension is to put the south-eastern district of the Soudan in communication with the seat of the nominal Government at Cairo, and also with the actual Government in London, as well as with the port of Aden, the chief military station] between India and Malta. It would now be possible, and events have rendered it not altogether improbable, for any of those large bodies of troops which are constantly being transported eastwards or homewards to be intercepted, and their movements directed from the seat of war; and in any case it will enable the home Government to be kept well informed of those disasters which military prophets now assure us are impending over the rest of the Egyptian garrisons. We cannot expect that the land line to Khartoum will hold out much longer; that it remains uninterrupted except by stress of weather is one of the mysteries of the situation, and when it fails, Suakim in the east will not unlikely be the nearest, though very distant, point from which intelligence good or bad can reach us of the doings in central Soudan. The appearance of the enemy in the vicinity of Khartoum would be immediately followed by the destruction of all wire communication northwards. General Gordon vanished into space some days ago, and will remain far removed from all telegraphic help, crossing the Nubian Desert, for a week longer, unless, as rumour has it, he was captured at the very outset. Events are moving so rapidly and so unaccountably that it would be idle to speculate as to what may happen if he never reappears, or what may be the consequences of Baker Pasha's defeat in the neighbourhood of Trinkitat; but in any case the port at which the Eastern Telegraph system is now surely established is the point to which all armies, victorious or discomfited, will gradually converge. There, too, will embark, if the Soudanese permit them, the inglorious legions whom the English Government has ordered to abandon the country. After then, the slave trade, it is said, will revive with much briskness, and people who engage in that sort of business will find Suakim a very handy place to which they may wire their orders. We may safely affirm, on the strength of passing events, that it was not on this sentimental ground that the Government demurred to giving the Eastern Telegraph Company that prompt encouragement one would have expected under the circumstances. It is well known that various formalities have to be gone through, and various sanctions obtained, in order that a cable may be laid and landed, and it was these incidents that caused the delay to which we have already alluded. The company naturally desire, and it seems to us have a right to demand, immunity from unrestrained competition in undertaking ventures of this sort for the exigencies of war. If some public-spirited company did not lay these cables the Government would certainly have to lay them, and as certainly would not sanction a rival claimant to the profits that may or may not accrue to it when peaceful times arrive. Any telegraph company that does the work of the Government without being paid for it is at least entitled to protection against envious competitors.

And this in an especial sense is due to the Eastern Telegraph Company. For more than eighteen months past it has acted as a sort of auxiliary arm to the British forces. Before Alexandria it shipped its cable and, as was said at the time, it enabled London to be virtually a spectator of the bombardment—a questionable privilege perhaps, but one that was the means of saving much bloodshed and averting further mischief. At Suez, also, with admirable forethought, the telegraph station was floated, and got out of harm's way, both operations being attended with no little danger to the non-combatant officers of the company. In this way not only was Downing-street kept in hourly communication with the fleets, but Cyprus and Malta were hardly lost hold of for a moment. But this was by no means all. Inde-

Digitized by Google

pendent communication with Port Said had now become indispensable, and the company promptly undertook the laying of the line. In the months of July, August, and September of 1882 the company spent some £62,000; and in the present year the operations already completed, and the contemplated connection of Aden with Perim, an island situated 100 miles distant, to be used as a coaling station, will cost a very considerable additional sum. Profit, it may be hoped and expected, will accrue from these patriotic enterprises; but profit was not the first consideration, as is obvious from the fact that profit had not attracted such enterprise there already. During the Egyptian war the company received praises and thanks on every hand, and are earning them no less just now. Our communications with the East are a matter of both political and commercial necessity to us, and they depend mainly on the energy, vigilance, and patriotism of the company owning the lines which traverse the Mediterranean and Red Seas. These lines have been duplicated as well as duplexed, and to this circumstance we owe the freedom from any serious interruption to telegraphic control of our Indian Empire and the great high road leading to it. We are not surprised to see the shares of the Eastern Company rising steadily in the market, as indeed its management has deservedly risen in public estimation.

## THE THEORY OF DYNAMO-ELECTRIC MACHINES.

(CONTINUED FROM PAGE 248.)

9. *Work done by the Electromotive and Mechanical Forces, on the Assumption that the Iron Core Rotates with the Coil.*

In actual dynamo machines the iron core is fixed to the coil, and rotates with it. We have now to see how far this influences the result. If the core rotates, the poles of the magnetism induced in it are continually changing their position relatively to the core, while remaining fixed in space. Hence each particular turn of the coil, although in the common rotation it keeps its position relative to the particular parts of the core unaltered, yet is continually altering its position relative to the poles.

If the motion is slow, we may assume that the poles of the core retain the same position in space, and that the strength is the same as when the core is at rest. If the motion is rapid, there will be variations both in position and strength; but we will neglect these for the present, and return to them later in connection with another action which occurs when the motion is rapid. We assume, then, that in the rotating core the poles have the same position in space and the same strength as in a core at rest.

First consider the induced E.M.F. This arises from the fact that the windings of the coil alter their position relatively to the poles; and therefore, under the assumption just made, it will be a constant quantity. Thus, to determine the work done by the E.M.F., we may use the equations (18) and (20, as already deduced for the case of a stationary coil.

In the case of the mechanical forces the matter is not so simple, since, according to the different circumstances of the motion, different forces may be brought into a position to do mechanical work. The force which the magnetised core exerts on the rotating coil with its current traversing it does work which in the case where the coil alone moves has been determined above, but which in the case where the core and coil form one body, and move together, is equal in amount but opposite in direction to that which the coil exerts on the magnetised core. There is, however, another force, that exerted by the fixed electro-magnet on the same magnetised core. This, in the case of a stationary coil, could do no work, but in the case of a rotating coil is capable of doing so, and must be compared as to its effect with the other amount of work already determined.

This can easily be done if we suppose that the core alone rotates, the coil and fixed magnet both keeping their position unaltered. If, now, their common action magnetises the iron core, the latter is, indeed, acted upon by forces from both, but its motion is nevertheless unaffected, because it is in the condition of a rotating body, in which the axis of figure coincides with the axis of rotation. But if these two forces fail to affect the motion of the core, it must be because the movements they produce are equal and opposite. In other words, the turning moment exerted on the core by the fixed magnet is equal and opposite to that exerted by the coil. But we have seen that the latter is equal and opposite to that exerted reciprocally by the core on the coil; whence it follows that the turning moment exerted by the fixed magnet on the core is equal, both in magnitude and direction, to that exerted by the core on the coil.

Therefore the work which, in the case of a rotating coil, is done by the fixed magnet on the core, has the same value as the work (determined above) which in the case of a stationary core is done by that core upon the coil.

It is true that when we work out these two quantities of work mathematically, we arrive at expressions which are apparently different. The latter, as shown in the last section, must be proportional to N and to $P_1$, and must therefore be of the form $-kNP_1v$, where $k$ is an unknown constant. The former will be similarly proportional to M and $P_2$, and will therefore have the form $-k'MP_2v$, where $k'$ is another unknown constant. These expressions appear quite different; but if we substitute for $P_1$ and $P_2$ their values as given in equation (16), we obtain

$$-k\frac{CMN}{1+\beta i}v \text{ and } -k'\frac{CMN}{1+\beta i}v,$$

and we have only to suppose that the two undetermined constants $k$ and $k'$ are equal, in order to bring the two expressions into unison.

Thus we find that that part of the work done, in the determination of which the circumstance whether the core rotates or not chiefly needs considering, is equal in both cases; and therefore, under the assumption already made as to the position and strength of the poles, the equation (19), obtained for the case of a stationary core, may also be applied to the ordinary case when the core rotates with the coil.

10. *Modifications of the Foregoing Results for High Speeds.*

It has been hitherto assumed that the magnetism induced in the rotating core by the action of the fixed magnet and the enveloping coil is the same as if the core were at rest. At low speeds this is approximately true; but at high speeds the comparative slowness with which the iron submits to alteration in its magnetic condition causes the poles of the rotating core to have a position in space and a strength somewhat different from what it would have if at rest. This condition of dynamo machines has not, so far as the author knows, been previously reduced to calculation.

First, as regards the position of the poles and the direction of the magnetic axis. In Section 7 the value of the angle $\phi$, which the magnetic axis of the stationary core makes with the direction opposite to that of the fixed electro-magnet, is given by equation (15). Now, if the core is rotating rapidly, we may assume that its magnetic axis is moved, in the direction of rotation, through a small angle proportional to the speed of rotation. If, then, $\phi'$ is the angle which the altered magnetic axis of the core makes with the direction opposite to the axis of the fixed magnet, we may put

$$\phi' = \phi + \epsilon v \quad . \quad . \quad . \quad . \quad . \quad . \quad (21)$$

where $\epsilon$ is a small constant.

Next, as regards the strength of the poles. This will be slightly less when the core rotates than when it is at rest. Probably it will be pretty nearly correct to assume that the altered magnetic moment has the same value as the component of the original magnetic moment, taken in the direction of the altered magnetic axis. This original moment, P, is given in equation (14). Hence, if we put P' for the magnetic moment in the rotating coil, we have

$$P' = P\cos\epsilon v \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad (22)$$

If we now resolve P', as we formerly resolved P, into two

Digitized by Google

components, one in the opposite direction to the axis of the fixed magnet and the other at right angles to this, and call these components $P'_1$ and $P'_2$, we have

$$P'_1 = P' \cos \phi' = P \cos \epsilon v \cos (\phi + \epsilon v)$$
$$P'_2 = P' \sin \phi' = P \cos \epsilon v \sin (\phi + \epsilon v).$$

Developing these expressions according to powers of $\epsilon v$, and neglecting (on account of the smallness of $\epsilon$) all terms above the first order, we get

$$P'_1 = P (\cos \phi - \epsilon v \sin \phi)$$
$$P'_2 = P (\sin \phi + \epsilon v \cos \phi);$$

and if we substitute for the two products, $P \cos \phi$ and $P \sin \phi$, their values given in equation (16), we obtain

$$\left.\begin{aligned} P'_1 &= \frac{C}{1 + \beta i} (M - \epsilon v N) \\ P'_2 &= \frac{C}{1 + \beta i} (N + \epsilon v M) \end{aligned}\right\} \quad . \quad . \quad . \quad (23)$$

In these expressions the terms containing $\epsilon$ produce, when the machine is going in the direction in which mechanical work is done and an electric current generated, an increase in the work and a diminution in the resulting current. If the machine is going in the opposite direction, so that the current is being applied to generate mechanical work, these terms go to increase the current and to diminish the work. The magnetic sluggishness of the rotating core has, therefore, in all cases an injurious influence on the efficiency of the machine. This influence may be somewhat diminished if the contact springs are given a different position at high speeds and at low speeds, but it can never be suppressed altogether.

In addition to this action, due to the sluggishness of the iron, another action may occur which is adverse to the efficiency of the machine, namely, the induction of the electric current within the iron core itself. Such currents are usually called "Foucault" currents, because an experiment by that physicist called special attention to them, although they had been known and explained long before that time. In fact the rotary motion which a magnetic needle receives when placed above a rotating disc of metal, and the damping effect produced by a shell of copper on the vibrations of a needle, are both phenomena due to these same currents, and were both thoroughly known and understood at the time when Foucault made his experiments.

If the iron core rotates under the influence of the fixed magnet, then, as in every conductor which is in motion relatively to a magnet, E.M.F. is induced within it. But as the core is also under the influence of the current passing through its own coil, the question arises whether this current also does not produce an induced effect. The conducting wire rotates with the core, and relatively thereto is at rest, and therefore any such induction can only be caused by alterations in the current itself. Such alterations do occur at certain places, viz., in those members of the coil which are passing under the contact springs. These perpetually recurring reversals of the current must have an inducing effect on the core.

It is easy to show, however, by a method similar to that used in Section 9, that the E.M.F.'s induced in the rotating core, when the coil rotates with it, and the above-mentioned reversals therefore take place, must be the same as if there were no rotation of the coil, and at the same time no reversals. Hence, to determine the induction, we may assume that the rotating coil is influenced simultaneously by a fixed magnet and by a constant current within a fixed wire. Thus we conclude that the forces which act to cause induction are the same as those which act to cause magnetisation, and of the latter we know that they have a resultant whose magnitude may be expressed by $\sqrt{M^2 + N^2}$, multiplied by a constant factor, and whose direction is given by the angle $\phi$ determined in equation (15). The E.M.F. induced in the core may cause the existence of closed circuits within the core itself. But this can be prevented if the core is made up of several parts, so separated that electricity cannot pass from one to another. In the Gramme machine this is effected by employing a ring formed of wire in place of a solid iron ring.

Should such currents exist in any important degree, their action will be two-fold. First, they have themselves a magnetic moment, which must be taken into account like other magnetic moments; secondly, they have a magnetising action upon the iron, and thus change the previous magnetic condition of the core.

The intensity of the currents induced in the iron core, and therefore the magnitude of this magnetic moment, is, on the one hand, proportional to the inducing force, and therefore to the magnitude $\sqrt{M^2 + N^2}$, on the other hand to the velocity of rotation $v$. It may therefore be properly expressed by $\eta v \sqrt{M^2 + N^2}$, where $\eta$ is a small constant. As regards the moment of the magnetism produced by these currents in the iron, it must be remembered that this iron is already magnetised by other and much stronger forces, and that this will have a considerable influence on the denominator of the expression we are seeking. In accordance with the value given in equation (14) for the magnetic moment P, we may represent the present moment by $\frac{D \eta v \sqrt{M^2 + N^2}}{1 + \beta i}$, where D is a constant corresponding to the constant C in equation (14). Since both the moments thus determined have a common axis, we may add them together, and we thus obtain a moment of the magnitude expressed by

$$\eta v \sqrt{M^2 + N^2} \left(1 + \frac{D}{1 + \beta i}\right).$$

The direction of the axis of the magnetic moment thus caused by induction is at right angles to that of the inducing force; so that instead of the angle $\phi$, which gives the direction of the force, we must use the angle $\phi + \frac{\pi}{2}$. If we wish to resolve the moment into components, which are in the same direction as the components $P_1$ and $P_2$ of the moment P, we must multiply it by $\cos \left(\phi + \frac{\pi}{2}\right)$ and $\sin \left(\phi + \frac{\pi}{2}\right)$, or, which is same thing, by $\sin \phi$ and $\cos \phi$ respectively. We then obtain, for the component in the direction of $P_1$,

$$- \eta v \sqrt{M^2 + N^2} \left(1 + \frac{D}{1 + \beta i}\right) \sin \phi,$$

and for the component in the direction of $P_2$,

$$\eta v \sqrt{M^2 + N^2} \left(1 + \frac{D}{1 + \beta i}\right) \cos \phi.$$

If we replace $\sin \phi$ and $\cos \phi$ by their values in equation (15), the expressions for the two components are

$$- \eta v N \left(1 + \frac{D}{1 + \beta i}\right) \qquad \eta v M \left(1 + \frac{D}{1 + \beta i}\right).$$

These two magnitudes must be added to the magnitudes $P'_1$ and $P'_2$, determined by equations (23), and due to the magnetic sluggishness of the iron, if we are to take full account of the induction within the iron core. This will give us the values of the components of the entire magnetic moment existing within the core. Calling these $P''_1$ and $P''_2$, we have

$$\left.\begin{aligned} P''_1 &= \frac{C}{1 + \beta i} (M - \epsilon v N) - \eta v N \left(1 + \frac{D}{1 + \beta i}\right) \\ P''_2 &= \frac{C}{1 + \beta i} (N + \epsilon v M) + \eta v M \left(1 + \frac{D}{1 + \beta i}\right) \end{aligned}\right\} \quad (24)$$

If, for simplicity, we introduce the symbol $\epsilon'$, where

$$\epsilon' = \epsilon + \frac{D}{C} \eta \quad . \quad . \quad . \quad . \quad . \quad . \quad (25)$$

the equations become

$$\left.\begin{aligned} P''_1 &= \frac{C}{1 + \beta i} (M - \epsilon' v N) - \eta v N \\ P''_2 &= \frac{C}{1 + \beta i} (N + \epsilon' v M) + \eta v M \end{aligned}\right\} \quad . \quad (26).$$

These equations, as being more general, may be employed instead of equations (23). For machines in which the currents induced in the core are insignificant, we have only to put $\eta = 0$, and $\epsilon' = \epsilon$, and we at once return to equations (23).

(TO BE CONTINUED.)

## CORRESPONDENCE.

### THE PHYSICAL THEORY OF THE GRAMME MACHINE.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: In an article which appeared in your last issue Mr. FitzGerald strongly criticises a letter of mine on the above subject, the statements made in that article plainly showing that, if the letter referred to has been read through, its meaning has not been comprehended. The writer of the article in question objects to the "lines of force theory," on the ground chiefly that it clashes with the law of Lenz, but it is well known to electricians that the "lines of force theory" *agrees in every particular with the law of Lenz*, and that results in electro-dynamics, whether deduced from the law of Lenz or from the "lines of force theory," are in complete accordance.

This discussion does not touch the point as to whether in questions of electro-dynamics the true result is pointed out by the law of Lenz or "the lines of force theory," for the result is the same in both cases, but it is contended that the simpler and more scientific method is to work out results in accordance with the "lines of force theory."

I employ the expression "lines of force theory" because it is a *theory* and not a hypothesis, as Mr. FitzGerald supposes. It is difficult to comprehend that gentleman's meaning when he talks of hypothesis in this relation. Let us consider whether the hypothesis of Ampère or the "lines of force theory" is the more characteristic of the barrenness which he so much deprecates.

If a unit pole is placed in a magnetic field a certain force is exerted upon the pole, which may be measured in dynes. The magnitude of the force exerted at every part of the field may be represented graphically by lines mapped out, so that the number of lines cutting a square centimetre in any part of the field is numerically equal to the force in dynes exerted at that point. Now there is no hypothesis about this. Here is a magnet which exerts a measurable force on a unit pole, and here is a graphical method of representing the force exerted by means of lines drawn in a particular way, which enables mathematicians to calculate with accuracy the E.M.F. developed in any closed circuit moving in the vicinity of the magnet. In terms of the number of lines of force added to or subtracted from a coil in a given time the quantity of electricity generated can be expressed, and we know of no other method of connecting the current generated in a coil with the strength of the field in which it moves. If Mr. FitzGerald has a better way to propose, by all means let us have it, but for my part I fail to see how the E.M.F. in a coil can well be expressed in terms of the magnitude of a hypothetical amperian current.

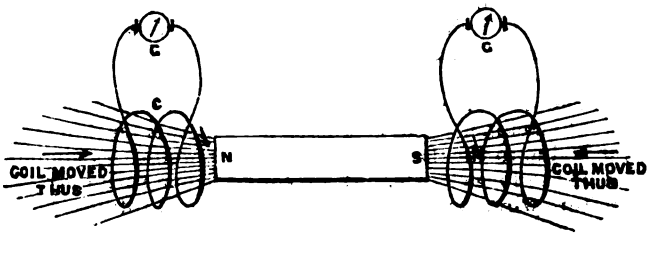
I would remind the writer of the article in question that with the *why* of the universe he has nothing whatever to do. It is the *how* of things that should interest and absorb the attention of the scientific investigator, and we have yet to learn why electricity flows at all in a coil when moved in a certain way. What we do know is that a current does flow, and we can determine the relations existing between the movement of the coil, the strength of field, and the current flowing; but I question if even with all Mr. FitzGerald's categories, generalisations, and carefully manufactured analogies, we can get nearer the *why* than this, that two particular facts are co-related in time.

Mr. FitzGerald objects to my writing of N lines of force and S lines of force, and says that this method of writing implies two sets of lines of force independent of each other. This, as probably most readers know, is merely a conventional way of stating whether a N pole or a S pole is the nearer to the face of the coil which we are observing. Even the much maligned "average electrical *savant*" must know that lines of force always form closed curves and pass from a N pole to a S pole, as shown in my diagram a fortnight ago.

Mr. FitzGerald declares that experiment flatly negatives the conclusions at which I arrived when considering the direction of induced currents according to the "lines of force method." This statement only proves that Mr. FitzGerald has failed to understand the theory which he criticises, and has not yet grasped the significance of the plan which he himself pretends to elucidate. Were it not that readers are likely to be misled by such statements it would not be worth while pointing out the fallacies in Mr. FitzGerald's article, but inasmuch as this discussion touches questions on which no full discussion has been published, it is not unlikely that the question is of great interest to the majority of your readers.

Mr. FitzGerald ought to know that a Gramme machine will work with a ring of wood instead of iron, but not *beautifully*, because the lines of force will be distributed over a larger area, and as a consequence of their straggling through the centre of the ring the coils at the brushes cannot enclose the whole of the lines of force, which they would do if the ring were of iron and of sufficient sectional area. The function of the iron ring is to increase the strength of the field, but more particularly to bring all the lines of force within itself, so that each pair of coils may when they pass the brushes enclose the whole of the lines of force.

The experiments Mr. FitzGerald made with the wire reel and bar magnet have no scientific value whatever. The fact of a gentleman having made an experiment, as recorded, with a bar magnet, where the lines of force go straggling in all directions, and applying the results obtained to the Gramme machine, where we have in addition to the iron ring a powerful S pole opposite the N pole, which gives to the lines of force a particular direction, is really too utterly unscientific to deserve one moment's attention at our hands.



Mr. FitzGerald's last criterion of the value of the theory advanced by "E" is a grand success, so far as proving the truth of "E's" theory goes. He really ought to apologise, *not* for making "a great point of it," but for overlooking "E's" plain statements, and misrepresenting him in consequence. "Is it a fact," he asks, "that adding N lines of force to a coil of wire produces a current in one direction, and that causing the coil to enclose S lines of force, produces a current in the opposite direction?" and "if so," he continues, "I may at once admit that the explanation of the action of the Gramme machine which I have derived from the theory of Ampère and the law of Lenz falls to the ground." I repeat his experiment. Let C represent a coil of wire of which the terminals are connected to a galvanometer, G, placed at a considerable distance from it. Bring the coil up to the N pole of the magnet, the current will flow in the direction of the arrow, that is in a direction opposite to the hands of a watch, *if we observe the side of the coil which is next the magnet.* Now bring the coil up to the S pole (as shown at the right hand portion of the figure) the current will flow in the direction of the arrow, or in the same direction as the hands of a watch, looking at the side next the magnet. I need scarcely add that the absolute direction of the current through coil and galvanometer is the same in both cases as seen in the diagram, but that inasmuch as we are regarding in the two cases the different sides of the coil, the current will be seen by an observer to flow from right to left and from left to right respectively. Mr. FitzGerald will observe, if he looks at the face of the coil which is the nearer to the magnet (a point, by the way, carefully emphasised in my letter) that the results completely harmonise with both the theory of Ampère and the law of Lenz. These laws, based as they are on eternal

Digitized by Google

truths, necessarily endure, while Mr. FitzGerald's conclusions, based as they are on misconception, fall to pieces. Mr. FitzGerald first adds N lines of force to the *right* hand side of the coil, then adds S lines of force to the *left* hand side of the coil, the current, as a matter of course, flowing in the same direction in both instances; but if Mr. FitzGerald repeats his experiment, using the same side of the coil in each case, he will assuredly find that the current will reverse.

In conclusion, Mr. FitzGerald's article has its comic aspect, or, at all events, an aspect which that gentleman means to be comic—instance his little jokes. But it has a serious side as well. It is a serious matter that a gentleman who is so unsparing in his criticism regarding the "pretensions to knowledge" of others, and who talks so glibly of the "calm confidence that proceeds from absolute ignorance" in others, should cherish notions so erroneous regarding a subject on which he obviously considers himself an authority.—Yours, &c., E.

## THE AMPERIAN CURRENT HYPOTHESIS.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: May I ask Mr. FitzGerald if he will apply his method of treating magneto-electric induction to the following cases:—

1. Two bar magnets are placed end to end, with poles of opposite name facing each other. In the space between a coil, whose diameter is small compared with that of the magnets, moves to and fro along the line which joins the centre of the pole pieces. According to Faraday's method of considering such a case (and I have no doubt also according to the facts) no current is induced in this coil, for there is no change in the number of lines of force which it cuts. How does Lenz's law apply here?

2. The converse case is presented by the Siemens direct-current machine. The magnetic field in this machine (so far as it is due to the field magnets alone) would be similar to that of the former case. If we consider one turn only of the armature wire, it will be seen that as the coil rotates about an axis parallel to the plane of the two poles its mean distance from either of them is constant, and there is no movement of approach or recession. But inasmuch as the coil during one-half of its revolution passes from a position in which no lines of force are cut to a position in which it encloses the greater part of the field, a current must be developed, which will be reversed as the coil passes through the position of least action. Again, how does Lenz's law apply?

In my previous letter I referred to Mr. Cunynghame's explanation of the Gramme ring. I do not, however, fully endorse that paper, as there is an obvious error or omission in it. Mr. Cunynghame has not noticed the reason why, when a given coil is leaving one of the poles and approaching the medial line, and the number of lines of force cut by it is therefore *increasing*, the current developed is still in the same direction as when the coil was approaching the pole and the number of lines passing through it was being *diminished*. The reason is, of course, that as the coil passes in front of the pole the *direction* in which the lines of force pass through it is reversed, thus preserving by the double reversal the orignal direction of the current.

Thus amended this explanation is substantially the same as that given by "E" in your last issue, with which I fully concur. I prefer, however, to distinguish the two faces of the coil—which are actually different—rather than to speak of N and S lines of force, which are the same thing under different aspects.

I have, of course, perceived the worthlessness of my hasty suggestion of last week *re* diamagnetism; my only excuse is that I wrote in great haste to catch the post. I am, however, willing to pay the penalty of rashness, and leave to Mr. FitzGerald, if he thinks it worth while, to expose my momentary oversight.—Yours, &c., W. H. SNELL.

Liverpool, 29th January, 1884.

P.S.—Since this letter was posted to you, Mr. Editor, the reply of Mr. FitzGerald to your correspondent "E" has appeared, and really it has puzzled me very much. I do not like to imagine that Mr. FitzGerald can have failed to make himself thoroughly acquainted with the theory he condemns—such an idea is almost inconceivable—yet I know not how else to account for his singular misapplications of its principles. Take only the "*experimentum crucis*" on which he stakes his argument. Here the N pole of a magnet being inserted into a coil produces a current in a given direction; the direction of the magnet (*and also of the coil*) being preserved the S pole of the magnet is now thrust into the coil, and a current is generated in the same direction as before. "Why c'tnly." The direction of the currents depends not only upon whether (so-called) N or S lines are added, *but also upon the direction in which they pass through the coil.* Now, in the second case the S lines of force are added to the coil *at the opposite side to that at which the N lines entered*, and the double reversal preserves the original direction of current.

It is, however, much simpler to consider only N lines of force, and a moment's consideration will show that the motion of the magnet tends in each case to increase the number of lines which, starting from the N pole, enter *the same face of the coil.* Hence the theory is in complete agreement with experiment. The explanation of the experiment in Fig. 3 of Mr. FitzGerald's paper is of the same nature, although Mr. FitzGerald says it "is not understood." I may also remark that this experiment is nothing to the point in discussing the Gramme ring, for the field of force is quite different.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: Much as I may respect and esteem Mr. FitzGerald and the general character of his views, I yet feel pleased that Mr. Snell should have entered protest against the fashionable absurdity involved in amperian currents.

Ampère himself may well occupy a high position among our greatest men of learning and ability, and his mathematical grasp of magnetic relations was something wonderful for his time; but as Newton had his weak points, so I have ever regarded the Ampère hypothesis as purely unnecessary and mischievous. When such hypotheses become handed down from one generation to another they become fixtures in the scholastic mind as *true* theories, and detrimentally replace the simple truth, and grandiloquent boasts are made of the power of prevision inherent therein. Nor is it sufficiently appreciated that these fertile inferences may be more legitimately and more efficiently derived from a true grasp of the facts and physical conditions involved.

A very large proportion of our present optical science was discovered under the *material* hypothesis of Newton and Brewster; but, whatever they may have thought of it, we now know that a sounder *dynamic* view would have proved more fertile in progress and discovery.

There are many indications pointing to the near advent of our discovery of the true nature and probably *material* character of electrical phenomena, but whether it proves to originate in matter or force, certain it is that cumbersome hypotheses are huge impediments in the opening career.

A wise interrogation of nature is nothing if it be not well made up of hypothetic elements; but we have undulatory and other hypotheses, now rampant and undoubted, which will not stand the investigation of another generation of physical progress.

Accepting the Maxwell definition of a gas, then the conception of its *necessary* pressure against the sides of a containing vessel is far more simple and sufficient in itself than can all the vagaries of kinetic hypothesis make it. If we cannot conceive it to be otherwise, then why undergo a course of collegiate education to be up in all the wisdom of the Egyptians? without which, woe be to any student wishing to pass an examination. To my mind the sorceries of our Accadian forefathers, or those of Egyptian lore, were innocent compared with the miraculous bombardments of kinetic theory.

Nor is the conception of linear polarity or magnetism at all a difficult one, so that we must fly off to miraculous ethers, or endless revolutions of frictionless molecules, &c.

Digitized by Google

It was an early conception of Grove that chemical decomposition and voltaism differed in this, that while the former was a confused assemblage of small circuits of action, the latter was a combination effecting a linear result; that in the decomposition of two binary compounds, each in equilibrio by itself, proximity or contact would first of all set up a + and a — directivity of static polarity, ending in a recombination to a more stable equilibrio. The latter, however, is not a *necessary* result, but one depending on a sufficient E.M.F. in the atomic circuit.

Grotthus, and, more recently, Helmholtz have clearly pictured to us this state of things in an electrolytic fluid with the H's all tending to one side, and the O's to the opposite, and ultimate action prevented by glass sides.

Now, if this be end to end polarity, or directivity, does it help our conception to entertain Ampère vagaries quite on a par with devoutly estimating the number of spirits which might dance upon the point of a needle?

A given effect may often be produced by varied means. We may set up directivity or linear polarity in a column of air, or in a bar of iron, by surrounding them with convolutions of wire carrying a current; but we may do the same by a purely end to end affection without any currents at all. But much more than this; we know that every wire carrying a current induces a static polarity at right angles all round its surface; and so clearly is this fact known and understood that we not only know of its cumulative effect by adding parallel wires, but we know the still more cumulative effect of passing the wires round and round any given space, and we can precisely foresee the character of the combined or condensed static effect thus produced, so as to determine beforehand which end shall be + or —, as the conditions may be.

I do say, then, that this curvilinear production, when clearly understood, offers no countenance or support whatever to the Ampère vagary.

I have entertained grave suspicions that very much nonsense is perpetrated about "Foucault currents;" but the subject is a difficult one, and may well demand further experiment or better elucidation. As a boy cannot eat his cake and keep it also, so it is equally clear that we cannot induce polarity without an initial form of current which reacts disadvantageously.

We cannot propel a boat without encountering a given resistance; but, accepting the fact, we go building larger and larger boats, while every addition increases the resistance. We may try by skilful shape to lessen any avoidable excess, but *the* fact remains and is acknowledged, leaving, however, a good margin of advantage.

Is it thus electrically? or do we to try to both eat and keep the cake. We cut and maim our magnets to prevent Foucault currents; but do we cut our own throats to avoid imaginary dangers, or do we resist an inevitable resistance which is inherent in the setting up of static polarity?—Yours, &c., SAMUEL E. PHILLIPS, F.C.S.

## ZINC PRIMARY BATTERIES FOR ELECTRIC LIGHTING.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: In reference to the letter of Mr. Ross under this heading, allow me as briefly as possible to correct a number of misapprehensions under which that gentleman is labouring.

In the first place, I hold no dogmas, and my teaching has always been to accept nothing in science that is not susceptible of experimental or mathematical proof.

Secondly, I am not "impressed" nor "oppressed" "by the belief that it can be proved that the minimum consumption of zinc in a primary battery is at the invariable rate of 2·022lb. per horse-power per hour." On the contrary, I state that the theoretical minimum, in the present condition of our electro-chemical knowledge, is ·8772lb., and I give the formula $Zn = \frac{\text{H.P. hours} \times 2{\cdot}022}{e}$, which shows that the consumption of zinc per horse-power per hour is *never* 2·022lb., excepting only in the almost impossible case in which the electromotive force ($e$) of each cell is exactly one volt. (What can Mr. Ross have been thinking about?)

Thirdly, I did *not* suppose that the E.M.F. in action (in the experiments made by Mr. Ormiston) was "obtained from a single cell;" nor did I write anything that could lead to the conclusion that I made this supposition.

Fourthly, I should agree with Mr. Ross in regarding as very "singular" and "original" indeed the view that because a "back electromotive force" of 1·49 volt is generated in a water-voltameter an equal back electromotive force is generated "in each cell of a battery." (What *could* have led Mr. Ross to imagine that I intended my readers to understand that this is the case?)

Fifthly, I did not "traverse the assertion that the consumption of zinc per horse-power of energy is *not* a constant quantity;" on the contrary, I proved (what every electrician knows) that this consumption is a *variable* quantity, and stated definitely the conditions under which it varies.

Sixthly, nothing in the researches of Joule, Favre, and Silbermann, Andrews, and Dulong can be shown in any way to have disproved, or to be opposed to, Faraday's law of definite electro-chemical action, according to which the passage of a given current for a given time necessitates the consumption of the same quantity of zinc in *any* voltaic or other electrolytic cell whatever—whether the zinc be acted upon by nitric, or by sulphuric, or by muriatic acid, or by any "combinations" of these acids.

Seventhly, "the illustrious Faraday" never wrote anything that by any stretch of imagination can be considered as opposed to his own discovery of definite electro-chemical action.

Eighthly, the current ($c$) corresponding to a horse-power electrical is not invariably 746 amperes, and, in fact, is *never* 746 amperes, except only in the case, almost impossible in practice, of the E.M.F. being exactly one volt. Therefore the formula, $W = Z\,C\,t$, quoted by Mr. Ross, does *not* show that 2·02lb. of zinc is necessarily consumed per horse-power per hour; and therefore the very high authorities quoted by Mr. Ross can scarcely be said to have "disproved" an assertion which, so far as I am aware, nobody has ever made.

Ninthly, in the quotation from Faraday's "Experimental Researches" given by Mr. Ross, the insufficiency of the theory of electro-chemical equivalents is not really admitted by "even Faraday himself."

Tenthly (and lastly), Faraday never made a series of experiments with the object of demonstrating any fact that is at the present time both asserted by Mr. Ross and disbelieved by—Yours, &c., DESMOND G. FITZGERALD.

## PROFESSORS AYRTON AND PERRY'S FORMULÆ.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: In the course of my researches my attention has been directed to an "original communication" in No. 47 of the *Journal of the Society of Telegraph Engineers*, by the above named professors, entitled "A Difficulty in Electric Distributions."

The formulæ given do not work out in practice, and either they are wrong or the printers have made an error. As these formulæ are likely to be much used if correct, may I trespass upon your pages in order to have the subject ventilated.

The formulæ given are:—

$$x = V - (c + c')(R + r') - c(r - r')$$

and $$x' = V - (c + c')(R + r') - c'(R' - r).$$

As I understand the subject they should be

$$x = V - (c + c')(R + r) - c'(r - r'),$$

and $$x' = V - (c + c')(R' + r') - c(R' - R);$$

or as $(R + r) = (R' + r')$ and $(R' - R) = (r - r')$.

Then they should be

$$x = V - (c + c')(R + r) - c'(R' - R),$$

and $$x' = V - (c + c')(R + r) - c(R' - R).$$

—Yours truly, E. E. A

## THE GRAMME RING.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: Whilst my friends Messrs. FitzGerald and Snell are discussing the question as to which theory of the action of the Gramme ring is correct, perhaps the following explanation may not be out of place in your valuable journal.

When a dynamo does work—*i.e.*, sends a current—there must, to be in accordance with the principle of the conservation of energy, be a reaction such as to oppose the motion of the armature. It therefore follows, when a coil is moving from the neutral line towards one of the poles, there will be repulsion; consequently, the polarity of the face of the coil approaching the pole will be of the same sign as the pole approached. Let the coil move further on till it passes the medial line and recedes from the pole; then, in order to maintain the above principle, there must be attraction between the coil and the pole—that is, their respective polarities must be of opposite sign.

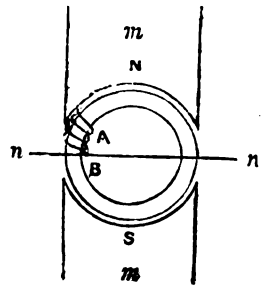

FIG. 1.

In the sectional sketch I have represented a coil, with its poles marked respectively A and B, moving towards the N pole of a dynamo. A is the approaching pole of the coil, therefore the current induced will flow in such a direction as to make A a N pole; consequently B will be a S pole. When the coil has moved past the medial line *m m*, it will be receding from a N pole. Thus the polarity of the end of the coil nearest to the pole will be S, but this end is B, which was S when the coil was approaching the N pole of the machine, and therefore the current must be flowing in the same direction in that half of the ring between the N pole and the neutral line *n n*.

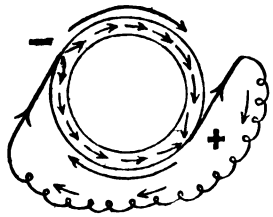

FIG. 2.

The same reasoning may be applied to the other half of the ring, which will show that the current in one half of the ring is flowing in the direction of rotation, and in the other half in the opposite direction.

The sketch in Fig. 2 shows particulars of this statement; the large arrows indicate direction of rotation, the small arrows direction of the flow of current.—Yours, &c.,

Isleworth, January 30, 1884. F. H. NALDER.

---

ELECTRIC LIGHTING IN THE CITY.—At a meeting of the Commissioners of Sewers on Tuesday, Mr. G. R. Innes, in reviewing the prospect of the year before them, said that "The electric lighting question had reached its commercial stage. All the matters of principle had been settled, and it now remained for the companies to show that they could carry it out." During the course of the meeting a proposal of the Edison and Swan United Electric Light Company to continue the lighting of Holborn-viaduct for three months at the cost of gas was adopted.

## ELECTRIC LAUNCHES.*

BY A. RECKENZAUN.

(CONTINUED FROM PAGE 235.)

The subject of secondary batteries has been so ably treated by Professor Silvanus Thompson and Dr. Oliver Lodge, in this room, that I should vainly attempt to give you a more complete idea of their nature. The improvements which are being made from time to time mostly concern mechanical details, and, although important, a description will scarcely prove interesting. A complete Faure-Sellon-Volckmar cell, such as is used in the existing electric launches, is here on the table. This box weighs, when ready for use, 56lb., and it stores energy equal to one horse-power for one hour = 1,980,000 foot-pounds, or about one horse-power per minute for each pound weight of material. It is not advantageous to withdraw the whole amount of energy put in; although its charging capacity is as much as 370 ampere hours, we do not use more than 80 per cent., or 300 ampere hours. Hence, if we discharge these accumulators at the rate of 40 amperes, we obtain an almost constant current for 7½ hours; one cell gives an E.M.F. of two volts. In order to have a constant power of one horse for 7½ hours, at the rate of 40 amperes discharge, we must have more than nine cells per electrical horse-power; and 47 such cells will supply five electrical horse-power for the time stated, and these 47 cells will weigh 2,362lb. We could employ half the number of cells by using them at the rate of 80 amperes, but then they will supply the power for less than half the time. The fact, however, that the cells will give so high a rate of discharge for a few hours is in itself important, since we are enabled to apply great power if desirable. The 47 cells above referred to can be made to give 10 or 12 electrical horse-power for over two hours, and thus propel the boat at a very high speed, provided that the motor is adapted to utilise such powerful currents. The above-mentioned weight of battery power—viz., 2,632lb., to which has to be added the weight of the motor and the various fittings—represents, in the case of a steam launch, the weight of coals, steam boiler, engine, and fittings. The electro-motor capable of giving four horse-power on the screw shaft need not weigh 400lb. if economically designed; this, added to the weight of the accumulators, and allowing a margin for switches and leads, brings the whole apparatus up to about 28cwt.

An equally powerful launch engine and boiler, together with a maximum stowage of fuel, will weigh about the same. There is, however, this disadvantage about the steam power, that it occupies the most valuable part of the vessel, taking away some eight or nine feet of the widest and most convenient part, and in a launch of twenty-four feet length, requiring such a power as we have been discussing, this is actually one-third of the total length of the vessel, and one-half of the passenger accommodation; therefore, I may safely assert that an electric launch will carry about twice as many people as a steam launch of similar dimensions.

The diagram on the wall represents sections of an electric launch built by Messrs. Yarrow and Co., and fitted up by the Electrical Power Storage Company, for the recent Electrical Exhibition in Vienna. She has made a great number of successful voyages on the River Danube during the autumn. Her hull is of steel, 40ft. long and 6ft. beam, and there are seats to accommodate 40 adults comfortably. Her accumulators are stowed away under the floor, as is the motor, but owing to the lines of the boat, the floor just above the motor is raised a few inches. This motor is a Siemens $D_2$ machine, capable of working up to 7 horse-power, with 80 accumulators. In speaking of the horse-power of an electro-motor, I always mean the actual power developed on the shaft, and not the electrical horse-power; this, therefore, should not be compared to the indicated horse-power of a steam engine. I am indebted to Messrs. Yarrow for the principal dimensions and other particulars of a high-pressure launch engine and boiler, such as would be suitable for this boat. From these dimensions I prepared a second diagram representing the steam-power, and when placed in position it will show at a glance how much space this apparatus will occupy. The total length lost in this way amounts to 12ft., leaving for seating capacity only 15ft., while that of the electric launch is 27ft. on each side of the boat; thus the accommodation is as 15 to 27, or as 22 passengers to 40, in favour of the electric launch.

Comparing the relative weights of the steam power and the electric power for this launch, we find that they are nearly equal, each approaches 50 cwt.; but in the case of the steam launch we include 10 cwt. of coal, which can be stowed into the bunkers, and which allows fifteen hours' continuous steaming, whereas the electric energy stored up will only give us 7½ hours with perfect safety. I have here allowed 8lbs. of coal per indicated horse-power per hour, and 10 horse-power giving off 7 mechani-

* Paper read at the Society of Arts on Wednesday, Jan. 16, 1884.

Digitized by Google

cal horse-power on the screw shaft; this is an example of an average launch engine. There are launch engines in existence which do not consume one half that amount of fuel, but these are so few, so rare, and so expensive that I have neglected them in this account. Not many years ago, a steam launch carrying a seven hours' supply of fuel was considered marvellous. Our present accumulator supplies 33,000 foot-pounds of work per pound of lead, but theoretically one pound of lead manifests an energy equal to 360,000 foot-pounds in the separation from its oxide; and in the case of iron Professor Reynolds told us in this place the energy evolved by its oxidation is equivalent to 1,900,000 foot-pounds per pound of metal. How nearly these limits may be approached will be the problem of the chemist; to prophesy is dangerous whilst science and its applications are advancing at this rapid rate. Theoretically, then, with our weight of fully oxidised lead, we should be able to travel for 82 hours; with the same weight of iron for 430 hours, or 18 days and nights continually at the rate of 8 miles per hour with one charge. Of course these feats are quite impossible; we might as well dream of getting 5 horse-power out of a steam-engine for one pound of coal per hour. While the chemist is busy with his researches for substances and combinations which will yield great power with small quantities of material, the engineer assiduously endeavours to reconvert the chemical or electrical energy into mechanical work suitable to the various needs. To get the maximum amount of work with a minimum amount of weight and least dimensions, combined with the necessary strength, is the province of the mechanical engineer; it is a grand and interesting study; it involves many factors; it is not, like in the steam-engine and the hydraulic machine, a matter of pressures, tension and compression, centrifugal and static forces, but it comprises a still larger number of factors, all bearing a definite relation to each other. With dynamo machines it has been the aim to obtain as nearly as possible as much electrical energy out of the machine as has been put in by the prime mover, irrespective of the quantity of material employed in its construction. Dr. J. Hopkinson has not only improved upon the Edison dynamo, and obtained 94 per cent. of the powers applied in the form of electrical energy, but he got 50 horse-power out of the same quantity of iron and copper where Edison could only get 20 horse-power—and, though the efficiency of this generator is perfect, it could not be called an efficient motor suitable for locomotion by land or water, because it is still too heavy. An efficient motor for locomotive purposes must not only give out in mechanical work as nearly as possible as much as the electrical energy put in, but it must be of small weight, because it has to propel itself along with the vehicle, and every pound weight of the motor represents so many foot-pounds of energy used in its own propulsion. Thus, if a motor weighed 660lb., and were travelling at the rate of 50ft. per minute against gravitation, it would expend 33,000 foot-pounds per minute in moving itself, and although this machine may give 2 horse-power with an efficiency of 90 per cent., it would, in the case of a boat or a tram-car, be termed a wasteful machine. Here we have an all-important factor, which can be neglected to a certain extent in the dynamo as a generator, although from an economical point of view, excessive weight in the dynamo must also be carefully avoided.

The proper test for an electro-motor, therefore, is not merely its efficiency, or the quotient of the mechanical power given out divided by the electrical energy put in, but also the number of feet it could raise its own weight in a given space of time with a given current, or, in other words, the number of foot-pounds of work each pound weight of the motor would give out.

The Siemens $D_2$ machine, as used in the launch, is one of the lightest and best motors. It gives seven horse-power on the shaft with an expenditure of nine electrical horse-power, and it weighs 658lb.; its efficiency, therefore, is seven-ninths, or nearly 78 per cent.; but its co-efficient as an engine of locomotion is 351—that is to say, each pound weight of the motor will yield 351 foot-pounds on the shaft. We could get even more than seven horse-power out of this machine by either running it at an excessive speed, or by using excessive currents; in both cases, however, we should shorten the life of the apparatus.

An electro-motor consists, generally, of two or more electro-magnets so arranged that they continually attract each other, and thereby convey power. As already stated, there are numerous factors, all bearing a certain relationship to each other, and particular rules which hold good in one type of machine will not always answer in another, but the general laws of electricity and magnetism must be observed in all cases. With a given energy expressed in watts, we can arrange a quantity of wire and iron to produce a certain quantity of work; the smaller the quantity of material employed, and the larger the return for the energy put in, the greater is the total efficiency of the machine.

Powerful electro-magnets, judiciously arranged must make powerful motors. The ease with which powerful electro-magnets can be constructed has led many to believe that the power of an electro-motor can be increased almost infinitely without a corresponding increase of energy spent. The strongest magnet can be produced with an exceedingly small current, if we only wind sufficient wire upon an iron core. An electro-magnet excited by a tiny battery of 10 volts, and, say, one ampere of current, may be able to hold a tremendous weight in suspension, although the energy consumed amounts to only 10 watts, or less than 1-75th of a horse-power; but the suspended weight produces no mechanical work. Mechanical work would only be done if we discontinued the flow of the current, in which case the said weight would drop; if the distance is sufficiently small, the magnet could, by the application of the current from the battery, raise the weight again, and if that operation is repeated many times in a minute, then we could determine the mechanical work performed. Assuming that the weight raised is 1,000lb., and that we could make and break the current 200 times a minute, then the work done by the falling mass could, under no circumstances, equal 1-75th of a horse-power, or 440 foot-pounds; that is, 1,000lb. lifted 2·27ft. high in a minute, or about one-eighth of an inch for each operation; hence the mere statical pull, or power of the magnet, does in no way tend to increase the energy furnished by the battery or generator, for the instant we wish to do work we must have motion—work being the product of mass and distance.

(TO BE CONTINUED.)

## THE BRITISH INSULITE COMPANY (LIMITED).

The second ordinary general meeting of this Company was held on Monday, at the Cannon-street Hotel, the Right Hon. E. P. Bouverie in the chair.

The SECRETARY read the notice convening the meeting, and the report of the directors was taken as read.

The CHAIRMAN said that the result of the accounts must be as disappointing to the shareholders as it was to the directors, but the truth was that they had only been on their legs and really at work for six months, and the business, therefore, was merely in its infancy, and was not such as they hoped it was likely to become. They had had a good deal of trouble in getting an appropriate place to put their works up, and they also had to get machinery devised of a special character, which took a considerable amount of time, so that they had not fairly got to work, and did not put the goods that they now made into the market till the beginning of last half year. He might say that the original idea which prevailed in the minds of the Board, and of those who joined the Company, was that they were likely to be able to supply in a very large way to the public the material which they made in a comparatively raw state, particularly to those using electric lighting and electric railways. A year and a half ago there was a certain rush towards electric lighting, and a rush after those electric appliances on a large scale which this Company was supposed to be able to supply. However, the result had been that there had not been that extraordinary expansion of the application of electricity to public purposes, to lighting especially, as was expected. It was not necessary for him to explain the causes of that, but he thought that a great deal of the explanation was to be found in the fact that the enterprise of electric lighting, which promised so well at the outset, had been overladen as it were by public interference—that instead of encouragement of every kind being given to its development and spread, it had met with such restrictions as prevented any Company from making any profit out of the operation of electric lighting. The consequence was that there had not been a demand for the patents of this Company. At the same time it was satisfactory to know that the only electrical railway that had been made in the kingdom, and he believed in the world, was the few miles which had been constructed by the late Sir William Siemens, and there the insulite had been adopted as an insulator, and the application had been perfectly successful. This Company supplied the material, and it had given, he was assured, every satisfaction, and had answered the expectations which had been formed of it, so that he thought without going further the scientific expectations formed with regard to this material had been realised and demonstrated. Of course, the more important question for them as shareholders of the Company was the commercial value. There had not been the demand that was expected for the electric light, and as the lighting of Birmingham alone would exhaust the whole of the supply of gutta percha in the kingdom, if there had been a great demand for the light the demand for this Company's materials must have been very great. Being disappointed in their expectations they turned their attention under the advice and with the assistance of Dr. Fleming to the application of insulite to sundry other small appliances, such as batteries. The figures in the report indicated the amount of gross business that had been done during the six months, for practically there was none before, and it was satisfactory to know that the month of January had yielded orders to the amount of £1,046, which showed, he thought, that the demand for these appliances was growing, and there was likely to be a large business done in the supply of them. They had a very large number of customers, no less than 670 accounts having been opened in the six months. Of course there was the question whether this was done at a profit, because quite recently their auditor, who had been looking into the accounts, had said that he was not quite satisfied that they were charging sufficiently high prices for what they turned out to make it a really thoroughly remunerative trade. The directors thought that there should be a close examination into their books, accounts, and stores, and therefore they asked their auditor to go thoroughly into the matter and

Digitized by Google

investigate everything. That had only just been undertaken, and the directors intended to call the shareholders together in about six weeks to give them them the result of that investigation. In the meantime he hoped that the shareholders would be willing to accept the formal motion that the report and accounts be received and adopted. Speaking generally his own notion was that this business was but in its infancy; and therefore, perhaps, it had cost more than it had returned, but he believed it was capable of being made a very large and profitable business. One evidence he thought of that was that the gentlemen who had taken their produce had come again for more, which showed that the public who had purchased what they made were satisfied with the results—of course it took a long time to establish a business of this kind in a new thing. He believed if they went to the expense of largely advertising they could make it pay, but they were obliged to husband their resources to the utmost of their power. He ought to mention that Sir George Rickards was unable to attend through a severe domestic calamity, and wished him (the chairman) to apologise to the meeting for his absence, and to say that he fully concurred in all the proceedings and the policy of the Board. In fact, so far as that was concerned they had never had any disagreements on any point whatever. They had tried to make the business profitable, but felt that it would take time to develop, and at the outset might involve a sacrifice on the part of the shareholders, but the prospect was that that would be more than returned in the future. There had been communications of a verbal character with the parent company—and he regretted that Mr. Easton was not present—with the view to this Company obtaining the patents for the rest of the world. He believed that the parent company would treat them liberally in this respect. If that could be done it would be an advantage to them, because they might be able to see their way to an export business, which from the fact of their being a British insulite company they were debarred from. There could be no doubt—he would not say of the commercial value of the patents—but of the scientific value, because in Germany, where things were scientifically tested and no patent was given without the public examining it and testing its value and originality—in Germany there was a patent for the insulite.

Mr. DOMMET seconded the motion for the adoption of the report.

Mr. PORTER said when this Company was first started it was said the insulite would be very valuable not only for electric railways but for ordinary telegraph works as insulators. If it was so valuable there would be an enormous demand for it, and there would be no difficulty in selling the material. But there was another thing that was even more important than that. Supposing the demand increased to an indefinite extent, still the question was, would it pay to produce the material? Looking at the accounts, he did not think it would.

The CHAIRMAN said that with regard to the insulators a certain number had been supplied to the Post Office, but the manager told him that the Post Office tried them for two years before they came to a conclusion as to their value. Of course if they found that they were not carrying on the business at a profit they would have to raise the prices. That point was one on which he hoped to give them some information in the course of the next few weeks, but he believed there was some fallacy in the statement of accounts, and that they were not transacting the business at a loss.

A SHAREHOLDER asked if there was any chance of the parent Company taking back their patents if this Company were willing to make a loss?

The CHAIRMAN: I do not know. I have not asked them that.

Mr. HARRISON asked whether they had supplied any of their product to any of the large companies who were manufacturing largely. For instance the Swan, who were putting up installations all over the country.

The CHAIRMAN replied that they had supplied the Edison Company with some, and they had also supplied some other people who supplied some other electric companies.

Mr. HARRISON understood that the Post Office thought unfavourably of it. He had placed it in water for four days and it split from top to bottom. They were told that water was not absorbed by their material, but from his own knowledge he knew that it was. He asked whether it could be turned at all?

The CHAIRMAN said that he had some things turned himself.

Mr. HARRISON would like to know whether the statements made in the prospectus were correct, and if the stuff now being manufactured were of any use at all. He thought that the report was most unsatisfactory, and that the statement of the chairman was still more discouraging. He thought that the position of the Company was hopeless, and that the more insulite they manufactured the more money they would lose. It appeared to him that a call would be necessary, even if they wound up. They had lost their money, and the only thing was to make the best of a bad bargain, and not lose any more. He thought that a committee of shareholders should be formed. He moved, as an amendment to the adoption of the report, the appointment of a committee of investigation.

Mr. IODEL seconded the amendment.

Mr. JACKSON said that it was only a question of time to exhaust the capital of the Company if they carried on business in the manner in which it had hitherto been transacted.

The CHAIRMAN said that if their article was not sold at a sufficiently high price it would have to be raised.

Mr. JACKSON contended that if they raised the price of their article nobody would buy it. They could not raise the price without losing the sale. He did not agree with the gentleman who had previously spoken, and he did not blame the directors that the Company had not been the success that was anticipated. Like many people who had made bad investments, they were likely to blame anybody but themselves. He knew that the parent company had had the opportunity of selling its patents to various other people, but they had abstained from doing so because they thought that the operations of this Company would enhance their value.

The CHAIRMAN said that he started with the statement in the report that it could not be considered that the present state of things was satisfactory. He was not a scientific man, but they had the best possible evidence that their article was a success from a scientific point of view, and if it were a success from a scientific point of view they ought to be able to make it a commercial success. It must always be borne in mind that if there was not a demand fully grown up they must endeavour to create a demand. The business was in its infancy, and it did not follow that because it had been unprofitable in the outset, and they had not sold as much as would pay, that the business would be unprofitable in the future. He had never tried the material with a screw himself, but Sir William Thomson stated that he had tried it with a screw, and he was assured that it had been successfully done, so that those small matters of technical objection were really worth nothing at all. To appoint a committee of shareholders meant to stop the whole thing, and it would be a vote of want of confidence in the directors, who had done their best to make the thing prosperous and successful. As to there being any statements in the prospectus that were misleading, he could not imagine that there were any. He did not think that there was a single statement that was not founded upon fact, and he was quite sure that intentionally the prospectus was not highly coloured.

Mr. ROBINSON KENDAL hoped the shareholders would leave the matter in the hands of the directors for another six weeks, when they would have the report of the auditors.

Dr. FLEMING said he would answer the remarks made by the last speaker first. In the first place he understood him to say that he feared that insulite did not compete advantageously as an insulating material with other materials. He said that the chief insulating materials were composed of vegetable substances, and that they (the Company) could not compete with them. They could compete with them. The whole of the gutta percha in the market would hardly be sufficient for laying down the electric mains of a town the size of Birmingham. The only way in which you could lay down insulating mains was by laying them in material of the sort that they produced, which could be moulded into bridges in which they could be laid, and as a complete answer to the remarks of the last speaker he might say he had now before him a proposal to prepare an iron mould to manufacture bridges of insulite on which to lay down on a very large scale such electric mains. He thought that that was a sufficient answer to the remarks of the last speaker. He thought, however, that certain of his remarks were calculated to seriously mislead, so he had better answer them a little in detail. In the first place he said that he had made some small experiments himself, which showed him that this insulite was not what it was intended and represented to be. He (Dr. Fleming) contended that he had not made the very smallest attempt to satisfactorily test the material in a proper way. No one could possibly secure that every one of the thousands of articles made, say in stoneware, should be perfect. There were sure to be some defective and cracked, and no one could ensure that every article made with insulite would be perfect, and one article of insulite taken at random certainly did not condemn the material. The only way in which one could obtain any knowledge on that point was to ascertain what the material had done in actual practice. He would take several instances. In the first place, it was put forward as a material which had very high electrical insulating qualities. Was there any case in which it had been found to have a valuable insulating property, so as to enable it to replace china and glass with advantage? Certainly there was, in the case of Leclanché battery cells. These cells were made of glass, and electrical leakage took place over the glass cells to an enormous extent. They had supplied a firm who used a large number of batteries of glass for synchronising clocks, and these glass cells had to be attended to very frequently, owing to the leakage that took place. At their request they had put their insulite batteries in, and the electrical insulation of these batteries was such that since they had had them they had had no difficulty in the matter. Here was a case where one did not rely upon testimonials either from scientific men or from anybody else. The results of actual practice, extending over months, were relied on. With regard to the remark made that the material absorbed water, of course it did not do so. It was perfectly obvious that if it did absorb water it could not remain in the open air, exposed to the weather, as insulators for telegraphs must be. A complete answer to that remark was that it was used in the Portrush Electrical Railway simply because it did not absorb water, and that was laid down upon 7,000 insulite bearers. He was informed by the engineer of the line that there was only a loss of electricity of three-quarters of a horse-power in the whole distance of seven miles. They first laid the railway on a bed of asphalte, but they found that they could not work the railway beyond two miles, simply because the loss of electric energy was so great. They then laid it with our insulite, and since then they had found not the slightest trouble. Then, again, the value of it was proved by the fact that where they made sales they got repeat orders. It was not at all likely that the high class electrical firms that they had supplied would come to them again and buy more unless it was satisfactory. That was the most convincing answer that he could give to the statement that the material was not what it was represented to be. He thought he had given a sufficient answer to the questions asked and the remarks made.

The amendment was then put and lost by a large majority, only five voting in its favour.

The motion for the adoption of the report was then put, and carried unanimously.

Mr. George Rickards and Mr. E. Easton, the retiring directors, were re-elected, and a vote of thanks to the chairman and directors then terminated the proceedings.

## THE SOUTH AFRICAN BRUSH ELECTRIC LIGHT AND POWER COMPANY (LIMITED).

An extraordinary general meeting of this Company was held on Tuesday at the Cannon-street Hotel, Colonel Coxon in the chair, for the purpose of considering a resolution that the Company be wound up voluntarily, and also to reduce the shares from £5 to £2 10s. each.

Mr. THOMAS J. SEEL (the secretary) having read the notice convening the meeting,

The CHAIRMAN said: Gentlemen, I will now invite any shareholder to propose the resolution you have heard read. It may be as well for me at the same time to tell you that we think that it will be better for you to let the matter drop, because it is scarcely to the advantage of a public company under any circumstances, I may say particularly under ours, to ventilate too much the affairs of the company, and on this occasion I may perhaps show you the way to avoid that by assuring you that there is no

Digitized by Google

use in proposing the resolution to wind up. We hold 200 proxies, which is more than sufficient to defeat it. It is absolutely certain on going to a poll the resolution would be defeated. I will leave it in your hands, it is a shareholders' resolution. Well, it is suggested that we might say a few words about our own policy. Gentlemen, you know it. There is not a gentleman who signed that requisition, certainly not one with whom it originated, who is not aware that there is not the slightest divergence between the policy of the directors and the policy of the shareholders in this matter. Everything we have done, every act, every counsel, every order we have given in the matter to our representatives in the Cape, have all pointed to the final winding up of this Company some day. That is, when it can be done to advantage, or when it can be best done. I may remind you that we have practically suspended all extensions of our operations. We have refused to take fresh contracts simply because the present position of affairs in the Cape made it impossible for the people there to offer us those contracts at a remunerative price. We have restricted our operations entirely to the fields upon which they at present exist, and even there we limit them entirely to the perfecting of the light, and with a result that challenges question. The lights at Kimberley are excellent, the lights at Cape Town are excellent, and our manager and electrician at Kimberley is a zealous, hard-working, intelligent, and very excellent fellow, and he has merited the thanks of the Company by the way he has conducted our affairs there. Captain Dunlop is at present in Cape Town, and says that nothing could be better than the manner in which the lights are received there, so much so that the Dock Company have asked us to take another contract. We have restricted ourselves to perfecting and working the lights in order that we might enhance the value of our property when the time comes to deal with it. The word realise has been suggested to me, but the less we talk of realising and winding up when we have a commodity to sell the better. You are all business men, and why should we go about under the banner, "South African Brush in liquidation?" What chance on earth should we have of getting anything for our property with such a motto? But, gentlemen, you all know our policy. There is not a single idea that we have concealed from you in private discussion. Why, therefore, is there any necessity of any public discussion on the matter? There is one matter I want to explain. Mr. Johnson made a mistake, no doubt an unintentional one, in calling attention to one item. I think it was £844 which he alleged was expended upon machinery. That amount, however, included a large number of carbons and other materials that were necessary, and a dynamo, not for any fresh work, but as a natural and necessary precautionary supplement to our dynamo at Kimberley, where we have thirty-two lights, and a circuit of seven miles. It is a very dangerous thing to keep working with one dynamo, and although we managed without it for some time, I think we have acted wisely in sending out a fresh dynamo.

The Rev. Mr. JOHNSTONE said that it was his intention to propose that the Company be wound up voluntarily, and although it was his opinion still that that course was decidedly the best, and he was prepared to support his view, still, under the circumstances that the directors would oppose such a course, and were able to control the voting power of the Company, it appeared to him best for the interests of the shareholders who had deposited their proxies in his hands that he should abandon the proposal. In order to pass a resolution of the nature of the one he intended to propose, it was necessary that it should receive the support of three-fourths of the shareholders' votes. There were 1,796 votes, so that as the directors had in their hands over 600 it was quite plain that unless they were open to conviction, which he supposed they were not, having spoken so very determinedly on the matter, it was useless to bring the question forward, and therefore he begged to withdraw the proposition. However, he guarded himself from expressing entire concurrence in all that had fallen from the lips of the chairman. He thought it was patent to every one who had examined the accounts that the position of the Company at the end of the year 1883 was distinctly less favourable than it was at the end of June, 1883; so that so far from the Company paying its way it appeared to him that the longer the thing went on the smaller would be the capital.

The CHAIRMAN said that Mr. Johnstone had forgotten that the Kimberley contract did not expire till the end of August. They must carry on till then.

The Rev. Mr. JOHNSTONE replied that the Kimberley contract was worthless, and even if were not, there would be no difficulty in keeping on the Kimberley contract and going into liquidation at the same time. There was no obligation on the part of liquidators to continue any contract if it were not a profitable one, and for that reason he should think it best to go into liquidation.

The CHAIRMAN stated that they hoped by the time the Kimberley contract had run out their lights would have become so indispensable to the people in Kimberley, or even before that, that they might make an offer to the Company to take over its plant. They were paying the Company a very high figure. The contract was made in palmy days, and there was no doubt that the Kimberley people could work it very much cheaper themselves, not being saddled, of course, with the tremendous cost the Company had to incur. That contract did not expire till the end of August, and in the mean time Mr. Atkinson, who was out in the Cape, was feeling the pulse of the different corporate bodies all over the country to find out what their feelings were about adopting the light on their own account. The Company would have been in a far better position to make terms if these questions had not cropped up.

A SHAREHOLDER pointed out that if the directors had agreed to write off the liability on the shares they would not have been mooted.

The CHAIRMAN said that nothing was ever farther from the thoughts of the directors than to ever call up a farthing of the liability on the shares. They merely wanted the moral support that the uncalled capital would give them if they wanted to dispose of their property. Now that people knew that they had no capital they would think that they could buy the Company up at their own price.

The Rev. A. COOPER: I suppose you intend taking definite action when the Kimberley contract is at an end.

The CHAIRMAN: Before that if we can.

A resolution was then passed to reduce the capital from one hundred thousand pounds to fifty thousand pounds, the twenty thousand shares already issued, and constituting the present capital of the Company, being reduced from £5 each to £2 10s. each.

The proceedings then terminated.

## THE JABLOCHKOFF ELECTRIC LIGHT AND POWER COMPANY (LIMITED).

An extraordinary general meeting of the shareholders of this Company was held at the City Terminus Hotel, Cannon-street, on the 1st inst., for the purpose of considering, and if approved, of passing the following special resolutions: — 1. That this Company be wound up voluntarily. 2. That William Augustine Spain, of 76, Coleman-street, London, chartered accountant, be and is hereby appointed liquidator of the Company. 3. That a general authority be and is hereby conferred on the said liquidator to transfer the business and property of this Company to a proposed new company when incorporated, and to be named the Jablochkoff and General Electric Company (Limited), or such other name as shall be decided upon, and to receive in compensation for such transfer shares or other like interests in the said Company, as contemplated by the 161st Section of the Companies Act, 1862. And for that purpose to enter into an agreement with the said new company for the sale to that company of this Company's business and property upon the terms of the draft agreement in that behalf to be submitted to the meeting.

Mr. JAMES WILSON presided.

Mr. FRANCIS R. REEVES (the secretary and general manager) having read the notice convening the meeting,

The CHAIRMAN said: Ladies and Gentlemen, as stated in the circular sent to you, since our meeting in last October we have done our best to hold this property for your benefit, but we have only been enabled to do so under the greatest difficulties. Petition after petition has been lodged against us by creditors whom we could not pay in consequence of the shareholders not paying their calls. The foundation of the whole of our difficulties has been caused by those shareholders withholding their money as soon as they saw that we were in difficulty, and also by our debtors having nearly all withheld the just payment of our claims. When we have been paid the money we have been obliged to take a reduced amount. Notwithstanding the petitions lodged against us, you must have seen very often by the daily papers that we have proved that all the statements made against us were false, as to the promotion of the Company, and the other statements that were made. All the verdicts given have been in our favour, but this has cost us a great deal of money. Professional wreckers of companies—that is now an acknowledged business, and as it is engaged in by people who have not large funds at their command it happens that, though we gain the cause, and with all costs against the opposite side, they having no money, the loss falls on us just as if the verdict were against us. We have all our works proceeding as usual, and we have the patents the same as we purchased them—for the Colonies, Great Britain, and Ireland. In the position I have indicated, finding we cannot go on for ever paying money to those who seek to gain undue advantage over us, we have thought it better to call you together to obtain your affirmation to a reconstruction of the Company, the terms of which will be read to you by and by. On the reconstruction, with our reduced capital, and with our works in a more prosperous condition—that is, full of work—we look for an improvement in our position. At present, people knowing that we are in a difficult position, not knowing whether we are going to live or not, abstain from making new contracts with us. All our fixed expenses, however, are just the same as if we were doing a larger amount of work, while the income from them is very much reduced. We are certain that we have a good and profitable undertaking. We have now not only the patents as we purchased them, but our works also, and if we can reconstruct the Company in the way proposed we feel perfectly certain that orders for lighting from private people and public bodies will flow in very quickly. I now beg to move the first resolution, as above.

Mr. A. R. MARTIN seconded the motion.

Mr. PERCIVAL SMITH thought, as to the proposal referred to by the chairman, that it was strange that the shareholders should be asked to give their consent to it without knowing what they were to have in exchange. Before consenting to a winding up of the Company, he thought that the shareholders should be informed of what they were going to get.

The CHAIRMAN: I have forgotten to mention one thing—that the Court has decided that we should be wound up. Upon the petition of Mr. Hulett they have appointed a provisional liquidator, who is the gentleman named in the second resolution. As far, therefore, as these two resolutions are concerned, we have no alternative whatever. As our solicitor observes to me, we want to get a voluntary liquidation if we can instead of it being compulsory, in order to save expense.

Mr. SMITH: But what are we going to have instead? What is the nature of the exchange we are going to make?

The CHAIRMAN: After these two resolutions are read the agreement will be read. As regards the first two resolutions they form an ultimatum. The Court have settled it for us, and we must have either a voluntary or a compulsory liquidation.

Mr. SMITH still contended that the shareholders ought to know first what they were going to have under the proposed reconstruction of the Company.

Mr. TAYLOR also suggested that the draft agreement should be read, and the first two resolutions submitted to the meeting afterwards.

The CHAIRMAN acquiesced in the suggestion, and

Mr. REEVES read the pith of the draft agreement. It stated that the capital of the proposed new company was to be £120,000 in £1 shares, of which 40,000 should be called ordinary, and 80,000 preference shares, bearing a dividend of 6 per cent., to be paid every year before the ordinary shareholders received anything. The preference dividend was not, however, to be cumulative. The ordinary shareholders were to take the remaining profits till they received a dividend of 6 per cent. for the year, both classes of shareholders thereafter sharing equally as to dividend. It had been agreed that the business, rights, assets, and effects of the Company should be sold as a going concern, the price to be paid by the new company being £55,000, of which £40,000 should be paid by the allotment and issue to the Company of 40,000 fully paid-up ordinary shares of the proposed Company. The remaining £15,000 was to be paid, as to £10,000, in first mortgage debentures of the new company, bearing 6 per cent. interest, and £5,000 in cash, or the whole in cash at the option of the directors of the new company, payable by instalments.

Mr. SMITH said he thought the shareholders should have had an oppor-

Digitized by Google

tunity of seeing the agreement before being asked to approve of it, and he suggested that the meeting should be postponed, in order that the shareholders might study the proposal before passing the resolution.

The CHAIRMAN, in reply to questions, said that the 40,000 ordinary shares of the new company would be distributed among the present shareholders of this Company. It was the opinion of the directors that the first two resolutions should be passed before the third was discussed.

Mr. REEVES: As to the suggestion that this deed or its principal points should have been in the hands of the shareholders before this meeting, that was absolutely impossible. The calling of the meeting was forced on the directors very hurriedly in consequence of two petitions being filed. There was only just time to call the meeting. The directors decided, after the meeting in October, when their appeal to the shareholders was not responded to sufficiently, that they would go in as soon as possible for a reconstruction of the Company, because certain gentlemen who had the means were willing to find the capital to carry on the business—only, however, on the condition that the Company should be reconstructed and placed on a more suitable basis from their point of view. Therefore the directors had decided to advise the reconstruction of the Company. There were only just the legal number of days in which to call a meeting before the matter came on in Court, and there was no time to circulate the agreement. The proposal, shortly, was this: The new company purchase the whole property (except the book debts) of the Company for £40,000 in 40,000 ordinary shares of the proposed new company, which will give rather more than one share in the proposed company for every existing share. The directors have forfeited a large number of shares, nearly 4,000, the effect of which will be to leave a number of shares in the hands of the liquidator to distribute among the shareholders. The cash and debentures, £15,000, which it is proposed to pay in addition to the 40,000 shares, will satisfy the whole of the claims against the present Company. In reply to questions, he added: This agreement is merely a draft one, and will be submitted for final approval before it is sealed. I think there is every probability that these shares will be subscribed—we have every reason to believe that they will. The subscribers will come in on very advantageous terms, as they get a valuable property for comparatively a small sum, and it is a going concern with every likelihood of becoming profitable. It is a business which is capable of development. We have the works in full going order, a large stock of plant and machinery, and a good name for the work we have carried out. There are a number of contracts offered at present—both arc and incandescent. No one can doubt that the electric light is steadily advancing in public favour. There is no large building erected or steamer launched without the electric light being adopted—in fact, it is the light of the early future. The system belonging to the Company is so cheaply manufactured that we can compete with any other company. There is no reason to doubt that the shares of the new company will be a very good investment, and as such should be subscribed for by the shareholders of the present Company. So far as the outside public are concerned I believe that the prospectus which will be issued will bear such statements and names as will be a guarantee for the shares being subscribed. So far as the present shareholders are concerned there is no question that the Company must be liquidated. The Court has approved a provisional liquidator, and to-morrow we shall have no answer to Mr. Hulett's petition. The question is, is it not better to carry out some such agreement as that proposed by the Board, and leave Mr. Spain, who has never had any connection with the Company until the present moment, to work the agreement out? The agreement will be submitted to you before it is finally sealed; but it seems to me that the course proposed to you should be carried out. In preparing the agreement the desire of the Board has been to protect the interests of the present shareholders, while having regard to the necessity of attracting further capital. Mr. Spain will have to approve this agreement before it is actually sealed.

The SOLICITOR stated that if the shareholders did not approve the agreement at the second meeting it would not have their approval. It was right for them to know that, once the liquidator was appointed, he had considerable powers in his hands to act independently of the shareholders as regarded the old company.

Mr. SMITH: But not as regards the new company.

The SOLICITOR: None whatever; but he will have the carriage of the winding up of the old Company on what he considers the best terms for the creditors and shareholders of the old company.

Mr. REEVES, in answer to a question, said that before the next meeting they would send to the shareholders an outline of the agreement.

Mr. HADEN seconded the resolution, which was carried.

On the motion of the CHAIRMAN, seconded by Captain EVERS (a director), the third resolution was subsequently agreed to, and the proceedings then terminated.

## THE ANGLO-AMERICAN BRUSH ELECTRIC LIGHT CORPORATION (LIMITED).

The third ordinary general meeting of the shareholders of this Company was held at the Cannon-street Hotel, on Wednesday last, the Right Hon. Lord Thurlow presiding.

The SECRETARY (Mr. E. Sarcke) read the notice calling the meeting, and the minutes of the previous meeting were confirmed. The report and accounts were taken as read.

The CHAIRMAN, in moving the adoption of the report and accounts, said that they had been laid before the shareholders in an unusually extensive and exhaustive manner. It was the wish of the Board on the present occasion to conceal nothing from the shareholders, but to place before them as complete and clear a statement as it was in their power to do of the present position and prospects of the Corporation, and to place it in a true and impartial light. It would therefore be the less necessary for him to enter into any lengthened details, but he felt it was due to the shareholders, who were so largely interested, and his colleagues on the Board, who had rendered him such hearty co-operation and devoted themselves with such untiring energy to the unravelling of the tangled skein of their accounts, that he should say a few words in explanation of some of the points which were raised. Having recounted the circumstances which rendered necessary the retirement of Sir Henry Tyler and the other directors who identified themselves with his policy from the board of directors last spring, and to the subsequent election of Mr. Herbert C. Gibbs, Mr. Edward Woods, and himself (Lord Thurlow) to seats at the Board, in place of those gentlemen, the chairman went on to say that the Board thus re-constituted entered at once upon its labours with the fixed determination of publishing the accounts of the Corporation, and of introducing economies and reforms in all departments of the Corporation's service wherever these could be effected consistently with efficiency. They were fortunate in securing the services of Mr. Frank Wynne as general manager and engineer, and of Mr. E. Sarcke as secretary, to carry out their instructions. The directors found that the accounts had hitherto been kept in a very complicated manner. The mode of bookkeeping employed was in many respects unsatisfactory, and in all respects very cumbrous—so much so as to render the task of tracing any particular item a matter of considerable difficulty. To such an extent was this the case that finally they thought it desirable to call in the services of an eminent firm of chartered accountants—Messrs. Cooper Brothers and Co.—who had gone most carefully over all the accounts, which were placed without the slightest reserve in their hands, and to whom the Corporation was indebted for their valuable report, and for a much more simple method of book-keeping which had been introduced into the office. It had been the view of the Board to make the balance-sheet as clear and comprehensive a document as possible. They had concealed none of their difficulties; they had exposed the skeleton in the cupboard to the gaze and criticism of every one, and although that course compelled them to issue an adverse balance-sheet, yet in his opinion there was nothing in their position which he knew of to cause uneasiness for the future, or to interfere with the prospect of a reasonable, if not a good dividend in the future, and possibly of an interim dividend in June, if only the suggestion which they had the honour to make to the shareholders was carried out in its entirety. He thought, in the first place, that it was desirable that they should disabuse their minds of the idea that the large sums entered on both sides of the accounts and written off represented hard cash completely sacrificed. He held that this really was not the case. They represented assets, in his opinion of great, although of undoubtedly fluctuating value, but assets which still remained their property as much as ever, although they might in the meantime be difficult of appreciation or realisation. Many of the items represented, he was thankful to say, the adjustment of troublesome and anxious claims, of which no more would be heard. As regarded the sums written off in reduction of the valuation of the stocks, he desired to say that in the event of a more favourable valuation of these stocks being made at any future time, the directors were of the unanimous opinion that such difference would be available, and would be properly applied to the formation of a reserve fund. This was a point the Board attached considerable importance to their appreciating fully. He could assure the meeting that to free the Corporation from expensive litigation; costing many thousands a year, and to enable their subsidiary companies either to get seriously to work in different districts, or to aid them in going into liquidation where it was evident that they desired to do so, had been their two great aims, and he might, without doubt or hesitation, congratulate them on the results. They had adjusted matters with Mr. Lane-Fox; they had arranged their difficulties with the Hammond Company. This was not quite all, because if they referred to page 5 of the report, paragraph 17, reference would be found to two comparatively unimportant actions that were pending when the report was issued. It was true they were comparatively unimportant in principle, but their settlement might have involved some thousands of pounds of the money of the Corporation, and he was glad to be able to inform the meeting that since the report was issued those two actions had been settled. Judgment in their favour had been given in court in one of them, and the other had been satisfactorily arranged out of court [applause]. He had a still more agreeable announcement to make with reference to litigation. If they turned to the preceding paragraph of the report—16—referring to the Gramme patent, a statement of the case would be found as it stood when the report was issued, but he was glad to be able to inform them that the result of certain negotiations, which had been conducted with very great skill, energy, and knowledge of the whole business by their vice-chairman, Mr. Sellon, was that they had come to an arrangement with the proprietors of the Gramme patent, the heads of their agreement being as follows:—The proprietors of the Gramme patent admitted that the Brush machine was no infringement of their patent, and that they had no claim on the Corporation in respect of it. The Corporation on their part had agreed to pay a royalty to the owners of the Gramme patent upon all machines made in which the Corporation might use the Gramme patent. Those were the brief but very satisfactory heads of their agreement with the British Company, which terminated their last piece of litigation, so that at this moment the directors came before the proprietors absolutely free from all legal complications [applause]. They had also arrived at satisfactory working agreements with their subsidiary companies, and here he desired to say that for such agreements to be good working agreements it was necessary that they should be satisfactory to their subsidiary companies as well as to themselves. No one-sided arrangement would be of any avail. They fully appreciated that the subsidiary companies had had their difficulties to contend against as well as the Corporation, and that they were entitled to every assistance that it was in the power of the Corporation (who alone could give it) to render to them. It so happened, however, that they were in a position to be able to make to the subsidiary companies a very important concession, exactly of the character which they most required, and happily without costing anything, by which he meant ready money to begin with, and no great loss in the future. There was one of those companies about which he felt sure the meeting would expect him to say something. He alluded, of course, to the Metropolitan Company. He did not desire, and it was not his intention to say very much on that matter. The directors deeply deplored the difficulties which had arisen between the board of directors of the Company and the shareholders, but for his own part he was not without hope that those difficulties might yet be surmounted, a circumstance which in the interests of electric lighting generally was much to be desired. Up to this time they had done all in their power to render assistance to the Metropolitan Company, and they would continue to do so. As regarded the Scottish and Dublin patents which had gone into liquidation, he maintained that the policy of the

Digitized by Google

Board was equally sound. The great body of the shareholders of both these companies desired to go into liquidation. The Corporation assisted them, and rendered it easy for them to do so by waiving the shares that they held in these companies, and in exchange taking the license and power to enter their territories and do business in them. The Scottish Company never really got to work, whether it was from over-caution or supineness he could not say. But since the liquidation of that company the Corporation had entered upon an active canvass across the border, with the result that they had already seen enough to justify them in the conviction that they had there a large field for doing an important and lucrative business [applause]. The year just past had been one of unceasing anxiety to the Board. The directors might have enjoyed dignity, but he could assure the meeting that it had not been accompanied with the proverbial ease. But what was more important was that they had been successful in obtaining several large cash payments for business accounts that were contested, and he might say that at the present moment they owed no man anything. Their trade outstanding accounts last year showed a balance largely in their favour. They owed their creditors in all a sum under £8,000, but their trade debtors, on the other hand, owed them a sum, after deducting all bad and doubtful debts, of £17,000, showing a very large balance in their favour. With respect to their banking account, that compared very favourably with what it did six months ago. They had now, as would be seen from the report, a balance at the bank in their favour of about £4,000, which contrasted very favourably with their position when he joined the Board eight months ago, when they owed the bank £25,000 [laughter]. Their actual position to-day was even more gratifying than appeared from the report, for moneys had come in since it was issued, and they had a larger balance at the bank than was there represented—a balance which more than covered all outstanding liabilities. They now saw their way clearly before them. Every day's post was bringing in orders and prospects of further orders. He was not at liberty of course to divulge names, but they were now negotiating for heavy contracts not only with leading commercial houses but with foreign and colonial Governments, and they had a largely-increasing business of private installations on their hands. There was an old saying, which he had never heard controverted, "that nothing succeeds like success," and in their case the corner seemed to have been fairly turned. Their general charges had been reduced during the last six months by one-half, while, on the other hand, the volume of their business had increased during the same period by over 70 per cent. It must be admitted that those figures spoke for themselves. The only thing that seemed, therefore, necessary now was to find the means of placing the shareholders in a position to profit by this welcome change. Their law advisers had informed them that this could only legally be done by reducing their capital—a proposition which was not to be lightly made, nor made at all unless it appeared first of all absolutely necessary to enable them to reap benefits in the future; and, secondly, it was justified only by a reasonable prospect of such benefits accruing. They held that the report showed that those two conditions were fulfilled. Great evils demanded great remedies—even great sacrifices. In this case the heroic remedy recommended involved no real, only an imaginary sacrifice. Their shares would shortly rise in the market—if this resolution were adopted—to a much larger figure than that at which they now stood, and they would also have the consciousness of knowing that they had entered on a period of accruing dividends. Their proposal was to reduce the capital of the Corporation by one-half—the effect of which on the financial condition of the Corporation was shown on page 8 of the report. It would enable them from that day to participate in the profits now earned, but which otherwise would have to be applied to reducing the larger adverse balance shown on the profit and loss account, and thus postpone the possibility of paying any dividend for an indefinite period. He wished to allude to one point in connection with this proposal, namely, the effect of the reduction of the capital on Article 56 of the Articles of Association, which governed the question of directors' remuneration. Under this article the directors were entitled when the Corporation paid a dividend of over 10 per cent. to a sum equal to one-tenth of all profits beyond that 10 per cent. It was proposed, therefore, to bring forward at the next general meeting a resolution altering that article by inserting "one-twentieth" in place of one-tenth [hear, hear]. He hoped that the resolution which they would propose before separating reducing the capital by one-half would be unanimously passed, because the Board were unanimously of opinion that the application of this remedy would at once place the Corporation in a brilliant financial position. After inviting shareholders to put questions on any subject not made clear in the accounts and his statement, the chairman concluded by formally moving the adoption of the report and accounts.

The VICE-CHAIRMAN (Mr. J. S. Sellon) seconded the motion, and in doing so said he wished especially to impress upon the proprietors the desirability, not to say the necessity, of showing as partners in this most interesting work a united front and determination to live down and put to shame the machinations against their property from which, unfortunately, they had hitherto greatly suffered. He expressed his unalterable belief in the unassailable value of their patent, and that they possessed a firm foundation for successful and economical electric lighting.

The CHAIRMAN, in reply to a shareholder, explained that the item of manufacturing account £7,709 5s. 6d. no doubt represented their manufacturing profit as shown on the twelve months, but with this qualification, that for at least six of them, and even to some extent for a longer period, they had been engaged in work which was not remunerative for one reason or another—for example, in exhibition, experimental, and various other manufacturing works that brought no money into the till, so that this item really represented the profit realised within the last few months.

Mr. HAMMOND animadverted on the policy which had been pursued eighteen months ago by distributing in dividends £230,000, and asked whether the old directors could not be induced to disgorge the money which they took then in virtue of the clause in the Articles of Association already referred to by the chairman?

The CHAIRMAN, in reply, also expressed regret that Mr. Hammond should have referred to the transactions of the old Board, but since he had done so he (the chairman) must remind the shareholders that at the time there was nothing that could be said against the Board from a legal point of view, and the policy of Sir Henry Tyler and his colleagues had received the approval of the shareholders in general meeting. As regarded the £99,000 referred to by Mr. Hayward, the course the directors pursued was taken under the advice of the eminent accountants whom they had called in to give assistance. To have left those shares out of the accounts altogether as Mr. Hayward wished would have been a manifestly improper course, because altogether they might at present be unrealisable except at a very heavy loss. In reality they represented a very large sum of money, and he saw no reason to doubt that in the course of time they might come to mean a very considerable portion of their capital. He hoped no one would go away with the impression that he attached no value to the asset, for, on the contrary, he attached great value to it. They had the authority of Mr. Thomas Sutherland, the chairman of the P. and O. Company, whom they had heard say that he had not the shadow of a doubt that the electric light would be the light of the future. There was no question Mr. Sutherland did not make that statement without sufficient reason for it. It was known that the P. and O. Company were actively taking steps to see whether they should not light up their whole fleet immediately with the electric light, and in the face of such circumstances it was impossible to controvert the fact that those shares might in the future come to be very valuable [hear, hear].

The motion was then put and carried unanimously.

Mr. SELLON proposed, and Mr. BROOKSBANK seconded, the re-election of the retiring directors, Lord Thurlow, Colonel Steuart, and Mr. E. Woods, which was unanimously agreed to.

Mr. CASH proposed, and Mr. BRAITHWAITE seconded, the re-appointment of Messrs. Cooper Brothers as auditors of the Corporation, which was also carried *nem. con.*

This concluding the ordinary business before the meeting,

The CHAIRMAN moved the following special resolution:—"That the capital of the Corporation, which now consists of £800,000, divided into 80,000 shares of £10 each, of which 13,701 shares have been issued and are fully paid, and 26,999 shares have been issued and have £8 per share paid or called up thereon, be reduced to £400,000, divided into 80,000 shares of £5 each, and that such reduction be effected by cancelling paid-up capital which has been lost or is unrepresented by available assets, to the extent of £5 per share, upon each of the 40,700 shares which have been issued, and by reducing the nominal amount of all the unissued shares from £10 to £5." He said they had carefully worked out the figures, and found that the effect of that resolution would be that if all the shares were £5 fully paid, the amount of £35,000, if such a sum were available, would give a dividend of £0·8674 per share all round—that was to say, the fully-paid shareholders would receive only about 17s. 4d. instead of £1 as at present, while the present partly-paid shareholders would receive about 17s. 4d. instead of 16s. as now. It was a matter of paramount importance, he said, that this resolution should be passed, and almost of equal importance that it should be passed unanimously in its present shape, so as to further strengthen the hands of the Board in the battle of the affairs of the Corporation which they had to conduct.

Mr. SELLON seconded the resolution, which was carried unanimously, and

Mr. STEWART having proposed a vote of thanks to Lord Thurlow for presiding, the proceedings terminated.

## SUBMARINE TELEGRAPH COMPANY.

The ordinary half-yearly general meeting of the proprietors of this Company was held at the Company's office, 2, Throgmorton-avenue, London-wall, on Thursday, the 7th inst., under the presidency of Sir Julian Goldsmid, Bart.

The SECRETARY (Mr. S. M. Clare) read the notice calling the meeting, after which the Company's seal was affixed to the register of shareholders. The secretary then read the directors' report, the statement of accounts being taken as read.

The CHAIRMAN, in moving the adoption of the report and accounts, said he had not a great deal to add to the information which they contained, but he would like to point out to the meeting in addition to the observations which he made at the last half-yearly meeting the exact condition of telegraphy between England and the Continent at the present moment. He had mentioned then that there appeared to be a stoppage of increase in telegraphic business, if not a slight decline, and he might say that this was confirmed by the experience of another six months. He found that up to the 31st of December, 1882, the number of messages transmitted for the six months was 1,422,178, and that up to the 31st of December, 1883, in the corresponding six months there were 1,396,634, which showed an actual falling off in the number of messages of 25,544. In addition to that the same process which he had mentioned at the last meeting—he meant the process of condensation or reduction of the number of words in each message—was still going on. In the period up to the 31st December, 1882, the number of words was 18,619,019, whereas in the period now under review the number of words was only 17,256,788, thus showing a decrease of 352,231. Consequently to put it in the form of average, whereas in the period up to December 31, 1882, the average number of words per message was 13·09, in that under review the average number of words per message was 12·33. That accounted not only for the change that had taken place in the receipts, but also for the remarkable difference there was in the number of words contained in each message. The shareholders would see that they had consequently a small falling off in the number of messages, as well as a larger falling off in the number of words they contained, resulting in the circumstance that the Company had smaller receipts than they used to have. The question they would all naturally ask was, How long would they go on in that way? Would they ultimately come to messages that would contain as a minimum one word? That of course was a physical impossibility, but at the same time there must be a minimum at which the compressive power of telegraphy would end. Where it was likely to be he was not in a position to state. He had no doubt himself that they had to face a still greater reduction, but he could not help thinking that the limit would be somewhere between 10 and 12 words per message. He hoped that at about 12 the reduction would cease. That it must cease he was certain, and from that time he looked forward to an increase in the amount of message work done by this Company between England and the continent. He thought it was quite right that the shareholders in a company like this

Digitized by Google

should know the exact state of affairs. They would see that it was a matter entirely beyond the control of the directors. All that they could do, as the French said, was—*constater les faits*—to take note of the fact, but they could not alter it. The only way that the individual shareholders could alter it was by sending as many and as long messages to the continent as they possibly could [a laugh]. The other matter to which he desired to refer was also mentioned in the report, and that was that on the whole the cables belonging to the Submarine Company were all in a reasonably good condition. But they had had great trouble with the two Government cables to Holland. The Government were alive to the condition of those two cables, and the matter was now under their very serious consideration. A large amount of correspondence had taken place on the subject, and he trusted that some solution of the difficulty would shortly be arrived at. Meanwhile, however, the cost of the repairs of those cables was very heavy, and must continue to be heavy, because they were in such an unsatisfactory condition. They had been interrupted between two and three months, and up to the present time, notwithstanding all the efforts of the Company's capable engineer, it had been found impossible to put them in order; but it was to be hoped if a new cable were put down that this difficulty might be overcome. The position of the affairs of the association in other respects was very much what it was on the last occasion when the Board met the shareholders. He was ready, as he was then, to answer any reasonable question on the part of the Board, but he thought he had stated all that was necessary in regard to their business. In conclusion he would like to add a word in support of the expression of regret which was contained in the report at the death of Mr. George Copeland Capper, who was the first auditor and an old shareholder of the Company. Practically, with the approval of the shareholders, they had had for many half years past a very careful professional audit of the accounts by one of the first firms of accountants in the City of London, and the duties being comparatively light, it was thought that two auditors were amply sufficient, and being also sufficient for the deed of settlement, it did not appear necessary to the Board to appoint another. He concluded by formally moving the adoption of the report and accounts.

The Hon. ASHLEY PONSONBY seconded the motion.

Several shareholders having asked questions,

The CHAIRMAN in reply said that when he used the word Government in connection with the Dutch cables, he meant the British Government. As he had already mentioned, the subject of the two cables to Holland had been a source of correspondence, interviews, and negotiations with the Government for a long time past, and he expected before very long some solution would be arrived at. It would, of course, be obvious to the meeting that he could not explain the nature of those negotiations. He did not know the exact age of the cables, as they were not the Company's property. They belonged, however, to the earliest period of telegraphic enterprise, and, as things now went, they were of very inferior quality. One of them was in a miserably weak condition, and the other was not at all satisfactory. With regard to the Company's concession, he thought if he had anything to say it would be very unwise to say it, in the interests of every shareholder in the room, and he was sure the gentleman who asked a question on that subject would not wish him to do anything to damage those interests [hear, hear]. Another gentleman had asked him a question with regard to the steamer. This was an old affair—of many years' standing. It was found necessary to have a steamer to keep the buildings, &c., in repair, and they would see by the *note bene* in the accounts that this amount was taken from the reserve fund of both companies—the French company and this Company—and included £15,105, the cost of the steamer, which was in course of repayment by half-yearly instalments, in accordance with the terms of the resolution passed by a special meeting of the proprietors on the 10th of May, 1870. With regard to the reserve fund, he believed that they always put down the exact amount which any investment cost them—that was to say, for example, the London and South Western Railway stock, which was put down at £2,400, actually cost the Company that amount. But even if they could realise some of these investments at a profit, they would only have to pay very much dearer to replace them. Therefore, he could not see why the Company should put brokerage into brokers' pockets by effecting changes which could not bring money into the coffers of the Company [hear, hear].

The motion was then put to the meeting, and carried unanimously.

The CHAIRMAN then said that with regard to the dividend—a point upon which one gentleman made an observation to the effect that he regretted that since the death of the late chairman the dividend had been reduced—he would only say that nobody deplored that circumstance more than the directors did, but the process which led to it was going on before the late chairman died; and he had pointed out to the meeting in the first part of his remarks that the reasons of that reduction were to be found in the fact that gentlemen unfortunately would send shorter messages now. The present Board had endeavoured to manage the business of the Company with the same zeal and assiduity which their late able chairman always displayed [hear, hear]. Though he would be glad to offer the shareholders a larger dividend, he could only offer the amount that had been received by themselves. He therefore begged to move, in accordance with their recommendation, that a dividend of 15½ per cent. be declared, to become payable on and after the 1st March next.

Mr. CLARK seconded the motion, and it was carried unanimously.

The proceedings were afterwards brought to a close by according a vote of thanks to Sir Julian Goldsmid for presiding.

## CUBA SUBMARINE TELEGRAPH COMPANY.

Report of the directors for the half year ending 31st December, 1883, to be presented at the twenty-fifth ordinary general meeting of shareholders to be held on the 13th February.

The directors beg to submit, duly audited, the balance-sheet and accounts for the half year ended 31st December last. From these it will be seen that the gross receipts, including the balance brought from last account, amount to £18,990 8s. 8d., and the gross expenditure, including the half of the annual payment on account of the 1881 cable, and the amount expended on renewals of cable and repairs, to £9,796 0s. 9d., leaving a sum of £9,194 7s. 11d. to the credit of revenue account. Of this the dividend on the preference shares will absorb £3,000, and leave £6,194 7s. 11d., out of which the directors recommend the payment of a dividend on the ordinary shares, at the rate of 7 per cent. per annum, free of income tax, the balance of £594 7s. 11d. being carried forward to the current half year's account. Considering that the extraordinary expenditure on renewals of cable and repairs during the half year has amounted to £4,021, the directors have not thought it necessary to make any further addition to the reserve fund beyond the interest thereon, which raises it to £55,350. The Batabano-Cienfuegos (original) cable broke down on the 17th ult., while the new shore ends of the Cienfuegos-Santiago 1875 cable were being laid. The former section not being duplicated, the Company's engineer immediately proceeded to the repair. This was successfully accomplished without loss of time, the interruption having continued for only eleven days, during which period messages were forwarded over the land lines of the Government. Mr. Keith has since successfully completed the laying of the new shore ends of the Cienfuegos-Santiago 1875 cable, and has also laid a new harbour length at Cienfuegos, and the directors have much pleasure in reporting that all the cables are now in good working order. The renewals and repairs have been carried out most economically, the whole cost being approximately £6,000. The tax to be returned by the Spanish Government referred to in last report has not yet been received, but it is hoped that the claim will be settled within a very short time. A further reduction has been made in the rates for Colon and Panama traffic to meet a like step on the part of the Central and South American Company.

## NOTES.

PERSONAL.—Mr. J. J. Fahie has left England to resume his official duties in Persia.

RATES TO CANTON.—The rates for telegrams to Canton have been raised 2d. per word.

TELEGRAMS FOR COREA.—Telegraphic communication has now been established with Corea.

THE PHOSPHOR BRONZE COMPANY.—This company have declared a dividend of 9 per cent. per annum.

COMMUNICATION INTERRUPTED.—Telegraphic communication with the Island of Islay, Scotland, is interrupted.

CABLES REPAIRED.—The cables between England and Ostend and between Cadiz and the Canary Islands have been repaired.

BRAZILIAN SUBMARINE TELEGRAPH COMPANY.—The traffic receipts of this company for the week ended the 8th inst., amounted to £3,740.

ST. GEORGE TELEPHONE COMPANY.—Mr. Justice Chitty will appoint a liquidator of this company at the Royal Courts of Justice on the 20th inst.

THE JERSEY CABLE.—Telegraphic communication with Jersey is temporarily interrupted. The communication with Guernsey is, however, working as usual.

TELEPHONE COMPANIES IN NEW YORK.—The Law Telephone Company and the Metropolitan Telephone Company, of New York, have joined hands and purses.

COMMISSIONERS OF SEWERS.—The commissioners have discharged their Select Committee on Electric Lighting, and left the matter in the hands of the Streets Committee.

THE SKRIVANOW BATTERY.—With one of these cells, weighing 100 grammes, M. D. Monnier recently obtained an E.M.F. of 1·45 to 1·50 volt., and a current of 1 ampere for 1 hour.

REDUCTION OF TARIFF.—The rates for telegrams sent to Cape Colony and to the Orange River Free State by the Eastern and the Submarine Telegraph Companies' routes, *viâ* Malta, have been reduced to 8s. 11d. per word.

THE ORKNEY-SHETLAND CABLE.—It has been ascertained that the fault in this cable is more serious than was at first anticipated. The cable laid between two of the north Isles of Orkney has been very seriously injured, and will require to be renewed.

THE TELEPHONE AT THE HOUSE OF COMMONS.—The United Telephone Company have arranged to keep a call room open at the House after 12 o'clock at night, to enable members to communicate with west-end subscribers, including the clubs, hotels, &c.

WESTERN AND BRAZILIAN TELEGRAPH COMPANY.—The traffic receipts of this company for the week ending the 8th inst., were £2,823, after deducting the "fifth" of the gross receipts payable to the London Platino Brazilian Telegraph Company.

WEST COAST OF AMERICA TELEGRAPH COMPANY.—The secretary of this company informs us that the tariff for telegrams from Great Britain to Buenos Ayres, and all stations in the Argentine Republic, via Galveston, is now reduced to 9s. per word.

THE BRITISH ASSOCIATION MEETING AT MONTREAL.—A Reuter's telegram from Ottawa states that the Estimates submitted to the Dominion Parliament include the sum of 25,000 dollars for the expenses connected with the meeting of the British Association at Montreal this year.

INTERNATIONAL SOCIETY OF ELECTRICIANS.—We have received the first number of the *Bulletin* of this society. It contains a list of the members and the rules of the society, together with a list of the works that have been presented to it and will form the nucleus of its library.

ELECTRIC LIGHTING IN QUEENSLAND.—Arrangements aer being made for illuminating the Brisbane Railway Terminus with the electric light. The Government has concluded a contract with the Australasian Electric Light, Power, and Storage Company to supply nine arc lamps.

COMMUNICATION WITH TONQUIN.—According to the latest intelligence from Tonquin, telegraphic communication between Paris and Hanoi was expected to be established yesterday (Friday). The telegraph steamer "Kangaroo" laid the cables along the bank of the Doson river on the 1st inst., and was expected to reach Saigon on the 12th inst.

DEPOSITS UNDER THE ELECTRIC LIGHTING ACT.—The vestries of St. George-the-Martyr and Chelsea have decided to allow the Metropolitan Brush Company an extension of time until next June for the deposit of the requisite money in compliance with the Electric Lighting Act. In the case of the Chelsea Vestry the deposit amounts to £20,000.

SS. "VALETTA."—The steamer "Valetta," launched at Greenock in November last, and built for the Peninsular and Oriental Company, was to sail for Melbourne on Thursday last. Her total length is 420ft., and her tonnage 4,911. Her engines indicate 5,000 horse-power. She is beautifully fitted up, and lighted throughout on the incandescent system.

CABLE INTERRUPTED.—The Direct Spanish Telegraph Company inform us that during the interruption of their Falmouth-Bilbao cable telegrams for Bilbao, Madrid, and other places in Spain can be promptly forwarded by the Eastern Telegraph Company's route. A duplicate cable is in course of construction and will shortly be laid between England and Bilbao.

EXHIBITION AT NEW ORLEANS.—An exhibition of the produce of the world is to be opened at New Orleans in December next. The work of erecting the building is now being undertaken. The main buildings will be furnished with 15,000 incandescent lights, while the grounds will be lighted by 3 arc lights of 3,200 candle-power each, together with such smaller arc lamps as may be required.

REMOVAL OF OFFICES.—With reference to the removal of Messrs. Hammond and Co. from 110, Cannon-street, to 117, Bishopsgate-street, we are requested to state that the address of the Hammond Electric Light and Power Supply Company remains as heretofore, 110, Cannon-street, E.C., the company having enlarged their offices by the addition of those lately occupied by Messrs. Hammond and Co.

THE ELECTRIC LIGHT WANTED AT SUAKIM.—The correspondent of a daily paper telegraphs from Suakim:—"It is very much to be regretted that the 'Euryalus,' although a large frigate and a flag ship, is not provided with an electric light. It would be invaluable to us here, as it would enable the whole approaches to the town to be searched with its beams, and no party of the enemy could approach our lines unobserved."

THE NATIONAL TELEPHONE COMPANY.—The directors of the National Telephone Company have resolved to declare a dividend for the past six months at the rate of 6 per cent.

Digitized by Google

per annum on the preference shares, and at the rate of 1 per cent. per annum on the ordinary, and to carry forward a balance of £3,942 0s. 5d. The unaccrued revenue carried forward to the credit of the next account amounts to £24,146 7s. 5d.

ROYAL METEOROLOGICAL SOCIETY.—The council of this society have arranged to hold at 25, Great George-street, S.W., by permission of the President and Council of the Institution of Civil Engineers, on the evening of March 19th next, an exhibition of thermometers. On the 20th inst., at the next ordinary meeting of the society, the Hon. F. A. Rollo Russell will read a paper on "The Sunrises and Sunsets of November, December, and January."

THE SUAKIM CABLE.—As mentioned in our leader last week we have soon discovered the advantages accruing from the Eastern Company in laying this cable. Not only has it been of great service to the Government in giving early information of the reverse sustained by Baker Pacha, but it has enabled them to correspond with Admiral Hewett, and to raise the drooping spirits of the defenders of Tokar with the promise of reinforcements, notice of which has, indeed, been sent to that town.

ELECTRIC LIGHTING IN FLOUR MILLS.—Mr. Wilson Hartnell, of Benson's-buildings, Leeds, has just fitted up the corn mill of Messrs. Reynolds and Haslegrave, at Wakefield, with incandescent lamps. The installation consists of one Crompton-Bürgin dynamo machine, of the compound self-regulating type, and 50 Swan lamps of 20 candle-power each. The lamps are scattered in all directions, amidst machinery in the stive room, and in many places where gas would be inadmissible. The result is highly satisfactory.

CONVERSION OF HEAT INTO POWER.—In the introduction to a series of experiments carried out with Otto gas engines at the Stevens Institute of Technology, U.S.A., Professor Thurston gives the following figures as illustrating the causes of waste in a gas-engine :—Out of the total amount of heat supplied the work of the pump consumed ·42; friction of mechanism, 4·10 parts; loss in exhaust, 23·55 parts; loss in water jacket, 46·90 parts; radiation, &c., 10·76 parts, leaving for useful dynamometric work only 14·27 parts out of the 100.

THE RESISTANCE OF SALINE SOLUTIONS.—In criticising the note recently presented to the French Academy of Science by M. Bouty, to which we called attention in these columns recently, M. Wortz remarks :—"M. Bouty has shown that the electrical resistance of saline solutions is the same when they contain equivalent quantities. But the chlorides experimented with did not contain equivalent quantities of metal, and there is reason to believe that molecules so different in form and size will offer different molecular resistance to the current."

A VERY OLD DISCOVERY.—A Liverpool paper states "that a discovery has recently been made in electric lighting, which, it is hoped, will solve the question how to bring the electric light into domestic use. All that is required are merely the ordinary metals and carbons and a peculiar kind of acid. These are put into an ordinary cell, and immediately the acid is poured in and the continuity established the electric force begins to develop." Our Liverpool contemporary will, no doubt, be grateful to us for pointing out that this "discovery" was made—well, several years ago.

ELECTRIC LIGHT FOR LIGHTHOUSES.—The Trinity House has given notice that the experimental oil, gas, and electric lights will probably be exhibited at the South Foreland about the end of this month. The lights will be shown from three temporary wooden towers, 180 feet apart, placed in a line bearing N.W. from South Foreland High Lighthouse, the distance between the high light and the first experimental light being 245 feet; consequently the permanent high and low lights will be to the seaward of the experimental lights. The electric lights from the High and Low Lighthouses will not in any way be changed or interfered with.

ELECTRIC LIGHT AT DORKING.—The capabilities of the Brockie lamp on the British system were shown to advantage at Dorking recently on the occasion of the visit of H.R.H. the Duke of Albany. A Brockie lamp of 2,000 candle-power was suspended in the centre of the High-street, and worked from an A Gramme machine, driven by a small engine at an adjoining brewery. Lighted at 8:30 p.m., this lamp gave a brilliant and steady light till extinguished at 3:30 a.m. The plant was fixed during the afternoon of the same day, and in a vault usually used as a beer store. The whole arrangements were carried out by Mr. A. de Saubergue, C.E., of 12, Delahay-street, Westminster.

BALL ROOM LIGHTING.—The committee of the Wellington Club, Liverpool, have entrusted the contract for lighting their large ball room by the electric light to the Liverpool Electric Supply Company (Limited). More than one hundred Swan 20 candle-power lamps have been arranged in the handsome cut-glass chandeliers with which the ball room is furnished, with the most brilliant effect. The generating machinery is fixed in a yard some distance from the club, and to prevent any possibility of breakdown accumulators are used, arranged in parallel circuit with the lamps. The electric light was first used at the ball a few days since, and was much admired. The work has been carried out under the superintendence of Messrs. Holmes and Vaudrey, of Liverpool.

THE TELEPHONE IN BELGIUM.—In several of the chief towns of Belgium the telegraph offices are connected with the telephone exchanges, so that subscribers can have a telegram telephoned to them directly it is received. A Belgian paper states that between the 1st and 27th of January no less than 771 telegrams were transmitted in this way in Antwerp, 1,025 in Brussels, and 1,272 in Liege. To show the saving of time accomplished by this means the same paper says that a telegram delivered into the Louvain office at 6:10 p.m. was received at the Brussels (northern) office at 6:17 p.m. and telephoned to the addressee at 6:19 p.m. The reply was telephoned back at 6:20 p.m. to the Brussels office and arrived at Louvain by 6:25. Other instances of equally quick transmission are mentioned.

ELECTRIC LIGHTING AT THORNTON.—The factory of Messrs. Peel Brothers and Co., of Thornton, near Bradford, has been lighted by electric lamps. The installation consists of one Crompton-Bürgin dynamo machine of the C type, and five Crompton-Crabbe arc lamps. These lamps are placed in the burling and knotting room. Burling, we may explain, requires a strong and good light. Hitherto the above firm have had to put their dark shades away, and work on light-coloured goods when it became dusk, but now they can not only work on dark-coloured goods at night, but have a better light than has recently been obtainable in the day time during the late foggy weather. The work has been carried out by Mr. Wilson Hartnell, of Park-row, Leeds, who is acting as agent for Messrs. Crompton and Co. for the north of England.

TELEPHONE LITIGATION.—A motion for a preliminary injunction brought by the American Bell Telephone Company

Digitized by Google

against the Overland Telephone Company came up for argument before the United States Circuit Court at Philadelphia on the 21st January. It was argued on the part of the Bell Telephone Company by G. N. Dickerson, of New York, and J. J. Storrow, of Boston, and for the Overland Telephone Company by Henry Baldwin, of Philadelphia, and A. J. Keasby, United States District Attorney, of New Jersey. The Overland Company asserts priority of invention of the telephone over Bell by Philip Reis, of Germany, and by J. W. McDonough, of Chicago, and also presents a part of the proof taken in another case to substantiate the claims of Daniel Drawbaugh, of Pennsylvania. The argument was closed on Thursday evening, and no decision is expected for some little time. The papers are very voluminous. We understand that the Overland Company's service in Philadelphia will be ready for work in a few days, and will then begin operations.—*Electrical World.*

DUNDEE AND DISTRICT TELEPHONIC COMPANY.—An extraordinary general meeting of this company was held in Dundee on Wednesday week, and it was resolved to increase the capital of the company from £5,000 to £10,000 by the issue of 1,000 shares of £5 each, and to reduce the number of directors from seven to five. At the annual general meeting, which was held subsequently, the chairman stated that "in spite of opposition this company had not only maintained its ground but had largely extended its operations and increased its usefulness. Moreover, the directors had seen their way to recommend a dividend of 9s. per share, being 10 per cent., or at the rate of 5 per cent. per annum for the past two years. While the competition had prevented the directors from declaring so large a dividend as they could otherwise have done, it had been far from an unmixed evil, as it had been the means of cheapening and extending telephonic communication to such an extent that Dundee was now known as the best telephoned town in the kingdom. Besides carrying forward £204 14s. 7d., the sum of £200 had been added to the reserve fund."

THE "ELECTRICIANS' DIRECTORY."—Having removed to our new premises, we are now enabled to publish our Directory for 1884. It is arranged on the same plan as that for 1883, but we have considerably enlarged it in many directions. We trust that the particulars relating to dynamos, arc and incandescent lamps, which we have taken some trouble to collect, will prove useful, as we think they cannot fail to do. Mr. Crawley contributes a table for correcting measurements in horse-power and watts, which will enable those who desire to do so, to obtain greater accuracy in their calculations. It is well known that the ohm is incorrect, and as the measurements of horse-power and watts, are based upon this unit, it follows that they must be incorrect also. Mr. Crawley's tables enable this inaccuracy to be corrected. Mr. Geipel has compiled a table relating to the cost of conductors, based upon Sir William Thomson's formula, which should prove useful to electrical engineers. Finally our readers will find that we have added many new names to our 1884 Directory, of which not a few are those of continental and American electricians, &c.

THE VICTORIA DYNAMO.—We have been favoured with the results of some recent tests made by the Anglo-American Brush Corporation with their Victoria dynamo, size $D_{\frac{1}{2}}$. The particulars of these tests are as follow :—Resistance of armature, ·025 ohm ; E. M. F. at terminals, 60 volts. External circuit consisted of 200 10 candle-power lamps, which were afterwards replaced by 100 20 candle-power lamps, the results in the two cases being exactly alike. Current in lamps, 120 amperes ; current in fields, 7·85 amperes ; current in armature, 127·85 amperes. Actual horse-power absorbed, 11·26.

| Electrical energy :— | | | Watts. | E. H.P. |
|---|---|---|---|---|
| In lamps | 120 × | 60 = | 7200 | = 9·648 |
| In fields | 7·85 × | 60 = | 471 | = ·631 |
| In armature (127·85)² × | ·025 = | | 408·6 | = ·547 |
| | | | 8079·6 | = 10·826 |

Efficiency of conversion $\frac{10·83}{11·26}$ = 96·15 per cent.

Electrical efficiency $\frac{9·648}{10·83}$ = 89·08 per cent.

Commercial efficiency $\frac{9·648}{11·26}$ = 85·68 per cent.

SIXPENNY TELEGRAMS.—In the House of Commons on Thursday, the 7th inst., Mr. Fawcett said, in reply to Mr. Alderman Lawrence, that no decision had yet been come to with regard to the particular plan that might be adopted to give effect to the decision that the minimum charge for inland telegrams should be reduced to sixpence. In addition to the three plans described in the Treasury Minute issued last year, five others had been for some time under the consideration of the Department ; but the attempt to estimate the financial results of adopting any one of them involved many intricate details. With regard to the date of the introduction of the reduced tariff, the Government had been reluctantly led to the conclusion not to introduce it at the date originally fixed, and the precise time would be left open until his right hon. friend the Chancellor of the Exchequer made his financial statement, when the Government would be in a position to determine it. —Lord John Manners asked whether any of the plans contained any reference to free addresses ?—Mr. Fawcett replied that one of the plans, all of which would be laid on the table, proposed free addresses, whilst another proposed free addresses limited to ten words, and another free addresses limited to eight words.

UNDERGROUND TELEPHONE WIRES.—In an article in the last issue of the *Popular Science Monthly* by Dr. W. W. Jacques, the author says :—"The American Bell Telephone Company has recently constructed two short lines of underground wires in the business section of Boston, and these give us excellent data from which to judge of the extent of technical practicability and the expense of putting all wires underground. We have seen that in Paris the retardation and induction are both obviated by the use of double and twisted wires in metallic circuit. It is necessary that all of the wires be in metallic circuit ; for, if a metallic circuit be connected to a single-line circuit, the disturbances are not removed. If a subscriber in one city wishes to talk with a subscriber in a neighbouring city, both cities must have metallic circuit systems and metallic circuits between the two cities. As the two lines constructed in Boston are short, only about one-quarter of a mile each, it was deemed best to use single-line circuits, hoping that the induction and retardation on so short lines would not be serious. The system is constructed as follows : Eight wrought-iron pipes, 3in. in diameter, are laid side by side in two rows, about 4ft. below the surface. At each street corner is built a brick chamber, large enough to admit a man, and with a cover flush with the street. The cables, of which several kinds are in use, run out from the basement of the central office through these pipes and up the side of buildings to roofs, from which they spread out to the subscribers by means of ordinary overhead lines. Conversation over these lines is not so easily carried on as by means of overhead wires, and it is frequently possible to overhear other conversation. This prohibits further extension of the

Digitized by Google

single-wire system underground, for technical reasons. The cost of the piping and chambers is in round numbers 50,000dols. per mile, and these pipes are intended to accommodate one thousand wires. The cost of the cables is from 60dols. to 150dols. per mile for each circuit, according to the kind of cable used. In round numbers we may estimate the total cost for one thousand wires at 150,000dols. per mile, or 150dols. per mile per circuit. The cost of piping and chambers would be nearly as great for one hundred circuits as for one thousand, as the cost of chambers and the labour of excavating and filling would be the same; so that the cost for one hundred wires may be estimated at 50,000dols. per mile, or 500dols. per mile per conductor. The cost per conductor thus increases enormously as the number of conductors diminishes, so that it would be clearly impossible to follow out the wires of an exchange system in all of their bifurcations."

Electric Lighting in Germany.—The German Edison Company have been hard at work during the past year, and we think it may interest our readers to have a brief *resumé* of what they have done. In Berlin, the head-quarters of the company, a small central station has been fitted up for lighting the Union and Resource Clubs. Each of these is lighted by some three hundred Edison lamps. From this station wires will shortly be laid to the Berlin Aquarium, which is to be lighted on the Edison system. Sixty lights have been put into the Café Lehman, and the same number into the Café Siechen. The warehouses of Messrs. Spindler, Dietrich and Busse, have also been lighted, one hundred lamps being used. During last summer a Sanitary Exhibition was held in Berlin, and one of its features was the Edison installation. The company lighted the Edison Pavilion, Café Baur, Military Kitchen, the Dining Pavilion, and also had lamps in various parts of the grounds. Over the dome of the Edison Pavilion the name Edison was exhibited in large letters formed of lamps. A commutator was so arranged in the machine room that one letter after the other could be thrown into circuit in rapid succession, the dynamo being only loaded with two letters at a time. The porter at the door had epaulets formed of incandescent lamps, as well as one in his cap. These were connected to copper plates in his heels, similar plates were let into the floor, and when the man connected his heel plates with these by standing on them, the lamps became incandescent, much to the astonishment of the visitors to the exhibition, who could not make out where the current came from. The company have wired several large buildings preparatory to introducing their system. Two of these are large cafés and others private houses. They have also wired their offices in the Leipziger Strasse. These they hope to light up directly their central station is ready. They have lighted up the following sugar factories in Germany, viz.:—Güstrow (two, 120-light dynamos), Neustadt, Silesia (one, 150-light dynamo), Ahrensbeck (one, 150-light dynamo), Gastrose (one, 120-light dynamo), Twilpstedt (one, 120-light dynamo), Papenteich (one, 120-light dynamo), Rositz (one, 250-light dynamo). The machines in these factories are kept running from 12 to 17 and 18 hours per day with their full load of lamps. The woollen factory of Herr Nicoli at Calbe has been fitted with 120 lights, the saw mill of Herr Crotogino at Rostock with 70 lights, the factory of Herr Hoffmann at Neugersdorf with 25 lights, and the porcelain factory at Wallefangen with 30 lights. The company also have in hand a central station at Berlin, the fitting of the steamship "Werra" for the North German Lloyd's with 300 lamps; the fitting of a Chinese man-of-war now completing at Stettin with 300 lamps, this being the second man-of-war for the same Government fitted in a year; an installation of 100 lights in the powder factory at Spandau for the Prussian Government; an installation of 60 lights in a copper-rolling mill at Neustadt; an installation of 40 lights in a spinning mill at Braunsweig, and an installation of 60 lights in a mine near Hamur.

Hemp versus Iron-covered Cables.—In an original communication to the *Journal* of the Society of Telegraph Engineers, Mr. James Graves says, *apropos* of Messrs. Trott and Kingsford's paper on this subject recently published by us:—"Iron sheathing is, no doubt, necessary, or some other durable substitute, to resist the rough usage to which shore ends of cables are exposed from abrasion on rocky ground, and between or beneath boulders on the beach; but even heavy shore ends have more than this to contend with when they cross unseen and unknown metallic beds, which consume them by slow but sure degrees. Perhaps it will scarcely be credited that a shore end, weighing 19 to 20 tons per knot, on the west coast of Ireland, covered with solid iron rods half an inch in diameter, was, some nine years ago, eaten up into a series of short lengths varying from less than 2ft. up to a few fathoms, several being less than two fathoms, and the cable being held together by the bare core. I have before me a piece of this iron, 19in. long, the middle 10in. of which is half an inch diameter, while the two ends are tapered to sharp points. Several pieces were recovered where every one of the iron rods was eaten through, and their ends tapered to points as sharp as bradawls. In picking up this cable—eaten up by galvanic action on metallic ridges at short distances apart—the bare core had to bear the whole weight in lifting, and in one case two such places were included between the bow-sheave and the water. A hempen hawser could not possibly have met with such a fate. On this same shore end a double serving of hemp was laid right-handed and left-handed, and over all a covering of preservative compound, forming a massive cable 8in. in circumference. The lay of the hempen yarns was very short. A piece of this external covering now before me shows that, while the top and sides of it are covered with a species of silica or coral, the bottom is worn quite through longitudinally, and the natural consequence of such wear and tear is simply to reduce the yarns laid on in contrary directions to lengths of about 4in. or 5in. each, and of course all the lifting strength is gone; and the presence of such a mass of material, enclosing the cable for three-fourths of its circumference, would prove mere dead weight when lifting it, as this was lifted, from a depth of 40 fathoms. And in this particular I cannot quite agree with Messrs. Trott and Hamilton in placing implicit reliance upon hemp for lifting strength when laid up spirally around the core, although several layers may be superposed, each contrary to the other in direction, and the lay of the yarns in each case contrary to both, as they suggest, to avoid kinking or buckling up when submerged. It will be seen that, if from any cause the hemp be worn through on one side to the core, the whole lifting-strength of the covering would be gone, as all the yarns would be separated as soon as the length of one revolution of the lay had been worn through. This naturally suggests that the lifting-strength in a hemp cable should be longitudinal with the core, around which the usual jute padding should be put to increase its diameter, as well as to form a soft bed for the core. Over the jute padding should be laid longitudinally as many of the strongest hempen cords as would pack closely round it, and then over these should come the servings suggested by Messrs. Trott and Hamilton. Should the outer spiral coverings get worn through, or even in addition two or three of the cords, there would still remain three-fourths of the strength, in addition to the core, for lifting purposes, instead of the whole strength being lost, and the core itself saddled with the whole weight."

## ELECTRO-CHEMISTRY.

### INORGANIC.

BY DR. G. GORE, F.R.S.

(CONTINUED FROM PAGE 249.)

**Separation of Antimony.**—Sb. Elec. chem. eqt. $\frac{120}{3} = 40{\cdot}00$.

A triad cation. This metal may be obtained from its solutions by all the methods of electrolysis. It is easily deposited from an acid solution of its terchloride by simple contact of various metals. Zinc, bismuth, tin, lead, brass, and German silver were coated with antimony by simple immersion in that solution; but platinum, gold, silver, nickel, and antimony were not. The simple immersion process is used to impart a lilac colour to articles of brass. A small quantity of hydrochloric acid, which has been perfectly saturated with freshly precipitated and wet teroxide of antimony, is precipitated by addition of a large bulk of water; the mixture is boiled until the precipitate is nearly re-dissolved, more water is added, and the mixture boiled again in like manner, and then filtered. The clear liquid is heated to the boiling point, and then perfectly clean articles of brass are immersed in it. They at once acquire a film of antimony and a lilac colour, and, by allowing them to remain a greater or less length of time, different tints of colour are obtained.

I have observed that zinc readily deposits antimony as a black powder by simple immersion in an aqueous solution of the mixed fluorides of antimony and potassium; that copper also deposits it as a black film and powder by contact with the acid hydrochlorate of terchloride of antimony, and that crystals of silicon did not become coated with antimony in an aqueous solution of terfluoride of antimony containing free hydrofluoric acid; also, that the oxide of iron upon a rusty iron wire was rapidly dissolved in a mixture of equal measures of solution of terchloride of antimony, and a saturated solution of sal-ammoniac. Watt coats copper with antimony by immersing it during about half an hour in a solution of one ounce of chloride of antimony, one pint of spirit of wine, with sufficient hydrochloric acid added to make the mixture clear. I have noticed that antimony is deposited, by simple immersion, from its ordinary chloride, as prepared for pharmaceutical purposes by zinc, bismuth, tin, lead, brass, and German silver, but not by antimony, nickel, silver, gold, or platinum. According to Raoult, magnesium sets free antimoniuretted hydrogen, but no metallic antimony from solutions of the metal (*Chem. News*, Vol. XIV., p. 27.) Gold, in contact with antimony, in a cold or hot solution of a salt of that metal, does not acquire a metallic coating (*ibid*, Vol. XI., p. 465).

The electrolysis of antimonic acid and solutions of its salts with electrodes of wood charcoal, or retort carbon, yields stibiomellogen, and with graphite electrodes stibio-graphitic acid (Bartoli and Papasogli, *Jour. Chem. Soc.*, Vol. XLIV., 1883, p. 592; *Electrician*, Vol. XI., pp. 28 and 101).

A very good solution for obtaining the pure metal by the separate current process, with an anode of antimony, is composed of:—

| | Parts by weight. |
|---|---|
| Distilled water ... ... ... ... | 12 |
| Pure hydrochloric acid ... ... ... | 1½ |
| Tartaric acid ... ... ... ... | 1 |
| Potassio tartrate of antimony ... ... | 1 |

The electric current should be from about two Smee elements, quite feeble, and of such a strength as to deposit a thickness of metal not exceeding $\frac{1}{3\frac{1}{2}}$nd of an inch per week. The metal thus deposited is hard, close-grained, of a slate-grey colour, silky lustre, and of decided crystalline structure. During deposition, when it has attained a thickness of $\frac{1}{10}$th of an inch, it sometimes cracks spontaneously, and becomes curved in fantastic shapes, or if deposited on a thin metal cathode, it causes the latter to bend.

**Electrolysis of Teroxide of Antimony.**—$SbO_3$. Molecular weight = 168. This compound, in a fused state, is reduced to metal by contact with charcoal.

**Electrolysis of Terfluoride of Antimony.**—$SbF_3$. Molecular weight = 177. This is a very soluble salt, and, unlike the chloride, is not at all decomposed by the addition to it of a large quantity of water. By electrolysis with a separate current of suitable strength, and an anode of antimony, it slowly yields a thick layer of the pure hard grey metal.

By employing a dilute solution of the fluoride containing free hydrofluoric acid, and using a current from two Smee cells, or by passing a current from ten such cells through a saturated neutral solution of the fluoride, during a long period of time, I have obtained very beautiful collections of shining grey crystals of the metal, which do not oxidise by exposure to air.

**Electrolysis of Terchloride of Antimony.**—$SbCl_3$. Molecular weight = 226·5. From a solution of this salt containing free hydrochloric acid, the antimony may be obtained by the separate current process, and an antimony anode, either in the form of the pure grey metal, or in that known as "amorphous" or "explosive" antimony, according to the degree of density of the current, and the composition and temperature of the liquid.

The acidified aqueous solution of chloride of antimony is an excellent conductor of the current; it dissolves an antimony anode freely, yields plenty of the amorphous metal, and does not deteriorate by use or by exposure to the atmosphere. It is, however, decomposed with greater or less rapidity by contact with zinc, cadmium, tin, lead, iron, brass, copper and German silver, each of which deposits the metal upon itself and dissolves. It is also decomposed by water, and therefore articles wet with water must not be immersed in it, and those taken from the liquid must be washed with dilute hydrochloric acid or a solution of tartaric acid previous to washing them with water.

**"Explosive Antimony."**—To obtain the explosive variety of metal from the usual acidified solution, the current should be of such a strength as to deposit not less than half a grain of metal per square inch of cathode per hour. If the strength is much less, the kind of deposit suddenly changes to the grey variety, sometimes preceded by formation of nodules of that kind upon parts of the surface of the cathode. The two kinds of deposit do not adhere firmly to each other.

A good solution for yielding the "explosive" variety is composed of one ounce of freshly precipitated teroxide or oxychloride of antimony, dissolved in five or six ounces of pure hydrochloric acid of sp. gr. 1·12, or it may be made by saturating two volumes of the acid with the oxide or oxychloride, and then adding one additional volume of the acid. The oxide employed should not be that which has been made by oxydising antimony with nitric acid, or with any mixture containing that acid, nor should it be that which has long been exposed to the air. A good solution may also be made by mixing together two ounces of water, four of hydrochloric acid, and eight of finely powdered potassio tartrate of antimony (*i.e.*, tartar emetic). Either of these mixtures will bear a very strong electric current without causing the deposition of a black powder. It yields its metal rapidly, and coatings of any desired thickness may be obtained. I have had some of quite half an inch in thickness. Deposits of one-tenth of an inch thick may be obtained from it in about seventy hours by means of a current from two or three Smee elements.

A suitable depositing liquid may also be prepared by the "battery process," *i.e.*, by immersing a large anode of antimony, and a smaller cathode of platinum, silver, or copper in the dilute acid, and passing a copious current until the metal is freely deposited.

The explosive variety of deposit has quite a different appearance from that of the other. It is highly smooth and lustrous, and of a steel-black colour. Its appearance, however, varies somewhat with the speed of deposition. It has the remarkable property that if struck, broken, or rubbed, whilst at the ordinary temperature, or if touched with a red-hot wire, it suddenly rises in temperature, usually about 650 F. degrees; the amount of heat, however, varies with different circumstances. Another difference between the pure variety of metal and the explosive kind

Digitized by Google

is that when deposited upon a cathode of mercury the former is absorbed by and alloys with the mercury, but the latter does not.

Like most electro-deposited metals, and especially the pure variety of antimony, the outer and inner surfaces of deposits of the explosive kind are in states of different cohesive strain, which sometimes cause the deposit to crack spontaneously in the depositing liquid and shatter to bits, evolving all its heat. Faint crackling sounds not unfrequently issue from both varieties of the depositing metals whilst forming in the liquids.

Sometimes, with a very dense solution of the chloride, worked rapidly, and the liquid and cathode not at all disturbed, a layer of deposited metal in the shape of a large button 1½ inch diameter, gradually formed round the cathode, just at the surface of the liquid.

A cylindrical bar of the explosive variety, about ⅝ths of an inch in diameter, formed upon a rod of tin ⅛th of an inch thick, when discharged by momentary contact of a heated wire, instantly evolved sufficient heat to melt the tin completely, and the tin ran out and remained liquid a short time. The change which takes place is propagated from particle to particle of the mass. By forming deposits of sufficient thickness upon helices of stout copper wire, and discharging them by application of heat to one end, the change was gradually transmitted to the opposite end, and the velocity of its propagation varied from 12 to 30 feet per minute, the velocity being greater the thicker and more freshly formed and perfect the deposit, and the weaker the cooling influences.

The temperature to which the deposit must be raised in order to produce a sudden discharge varies according to several circumstances, but is usually about 200° or 210°F. in an air bath; the heat, however, of the substance begins to discharge when the metal is heated to between 170° and 190°F., and if a piece of the substance is kept in water maintained at a temperature of 190° to 200°F. during one or two hours, it gradually discharges the whole of its heat. By careful manipulation, keeping one end of a rod of the substance hot and the other cold, the former end only loses its singular property. By carefully breaking thin pieces to small bits between surfaces of wood in ice-cold water, and then triturating them very carefully under such water in a mortar, the active metal may be obtained in a state of powder, with its heat-giving power undiminished. The thermic property gradually diminished by lapse of time, the powdered substance losing it the most quickly; that of a massive deposit disappears in a period of one or two years.

The specific gravity of the pure crystalline variety of deposit varied from 6·369 to 6·673, whilst that of the explosive kind varied from 5·739 to 5·944. Their electro-chemical equivalents also were different, and were determined by electrolysing their solutions in a single undivided circuit with one of cupric sulphate, and weighing the three deposits. I then found from 42·30 to 43·81 parts of the active kind, and 40·41 to 40·79 parts of the grey variety for each 31·7 parts of copper.

The discharge of heat in the explosive kind, whether sudden or gradual, is attended by alterations of the substance. From a bright black, highly lustrous surface, like that of iodine or crystals of silicon, and a bright vitreous-looking fractured surface, it changes to a dull grey earthy appearance and granular fracture. Its cohesive power also changes; and it acquires a strongly acid taste.

As the sudden discharge was attended by evolution of an acid fume (an effect of the heat), and the substance usually lost about 3·5 per cent. in weight, consisting chiefly of chloride of antimony, I made two analyses of the freshly-formed substance deposited from a pure solution of the chloride. The following were the results:—

| | No. 1. | | No. 2. | |
|---|---|---|---|---|
| Sb | 93·36 | | 93·51 | |
| $SbCl_3$ | 5·98 | 6·44 | 6·03 | 6·24 |
| HCl | 0·46 | | 0·21 | |
| | 99·80 | | 99·75 | |

It appears, therefore, that the deposit is a species of chemical compound of the metal with the ingredients of the liquid; and that during the change its state of chemical union is destroyed. R. Böttger has stated (*Chemisches Central Blatt*, 1875, p. 674) that the freshly deposited active metal contains occluded hydrogen; but this has been contradicted.

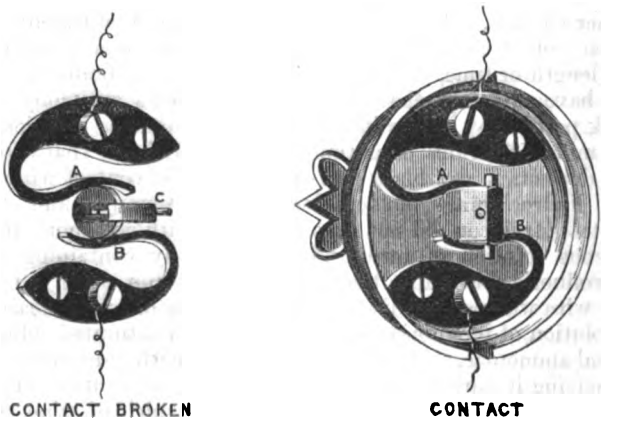
Smee appears to have been the first to deposit this variety of antimony, but not to notice its singular property; but since I first observed it in October, 1854, several persons have rediscovered it (see *Comptes Rendus*, Vol. LXXXIII., pp. 854—857; also *Dingl. Poly. Jour.*, Vol. 207, p. 427, and *Jour. Chem. Soc.*, Vol. XI., p. 1,007).

A solution composed of the double chloride of antimony and ammonium, with free hydrochloric acid, may be used instead of that of the acidulated simple chloride for depositing the metal, but possesses no very great advantages.

(TO BE CONTINUED.)

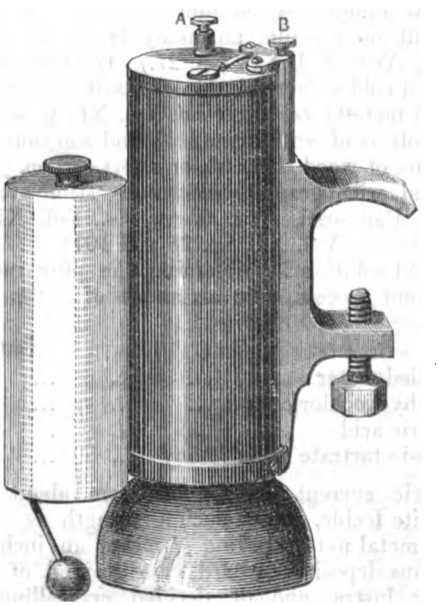
## A BICYCLE BELL, AND SWITCH FOR INCANDESCENT LAMPS.

The switch herewith illustrated has been designed by Mr. Volk, of Brighton. It consists of two springs, A and B, of hard copper, with a contact-making piece C.



Volk's Switch for Incandescent Lamps.

Mr. Volk has also contrived a very ingenious little electric bell for use with bicycles. It consists of a chloride



Volk's Bicycle Bell.

of silver cell in an insulite case, with coil and bell attached as shown. The apparatus can be attached to the bicycle, or, for the matter of that, anywhere desired, by means of a screw. Contact is made by means of a switch or push connected to the terminals A and B.

## CORRESPONDENCE.

### "THE PHYSICAL THEORY OF THE GRAMME MACHINE" AND "THE AMPERIAN CURRENT HYPOTHESIS."

TO THE EDITOR OF THE ELECTRICIAN.

SIR: In replying to the letters under these headings in your last issue, let me hasten to admit, in justice to "E," that, having in view other cases besides his own, I *did* overlook the significance of the proviso, in his letter on p. 254, "always remembering that we are looking on that side of the coil which is the nearer to the magnet." This of course means that if neither the direction of the coil nor that of the magnet be reversed, the "addition of north lines of force" to the coil produces precisely the same effect as the "addition of south lines of force," although if the observer reverse his own position in relation to the coil the apparent direction of the current is, naturally, reversed. Now, one of the objects of my last communication under the former of the above headings was to obtain a very clear admission of this point from those who are at the present time supporting the "lines of force" explanation of magneto-electric effects. The use I intended and intend to make of this admission is the perfectly legitimate one of supporting the view I have expressed as to the sufficiency, simplicity, and substantial truth of the explanation of these effects by the theory of Ampère and the law of Lenz, and as to the artificiality and often mischevious character of the alternative explanation.

The object in question has been fully attained, but in a somewhat ludicrous manner. I am informed by "E" that if I "look at the face of the coil" I shall observe "that the results completely harmonise with both the theory of Ampère "and the law of Lenz." Indeed! I should be glad to know what results do not harmonise with this law and that theory. With equal eloquence and presumption (evidently resulting from premature jubilation), "E" thus proceeds:—"These laws, based as they are on eternal truths, necessarily endure, while Mr. FitzGerald's conclusions, based as they are on misconception, fall to pieces." Next, "E" gives me some information, which is a direct consequence of the theory I am supporting, and with which, moreover, I have been familiar for a quarter of a century at least; and, "in conclusion," he says, "Mr. FitzGerald's article has its comic aspect!" *Pulmam ferat!* I should say, were it not for Mr. Snell, who follows with a repetition of the same information—the very statement I aimed at eliciting, viz.:—"The direction of the currents depends not only upon whether (so called) N or S lines are added, *but also upon the direction in which they pass through the coil.*"

Before proceeding further, let me give "E," in all kindness, a word of advice. When you write anonymously, "E," and your opponent is not anonymous, avoid always the faintest semblance of personality. The reason for this rule will, I hope, be obvious to you without reflection.

And now let me endeavour to bring into due prominence the points really involved in a discussion which tends to become somewhat desultory, but from which your readers might reasonably expect to derive something more than amusement. This discussion originated in an explanation of the action of dynamo-machines of the Gramme type; for which explanation I claim that it covers not only all the known facts in relation to magneto-electric induction, but also others that have been overlooked. It exhibits the Gramme machine as one which is not perfect, either theoretically or practically, but which is susceptible of improvements which may possibly be of considerable importance. This explanation was followed by another, given by "E," which I characterised as "a very neat and concise illustration of a mode of explaining magneto-electric phenomena, which I regard as artificial, if not fanciful, and as being likely to lead into error." According to this second explanation, the Gramme machine is theoretically a very perfect apparatus indeed for the conversion of mechanical into electrical energy, and would not be, from an electrical point of view open to improvement. It is of course incumbent upon me to show if possible, by fair argument and appeal to experimental fact, that the explanation given by "E" is defective. The more abstract grounds of objection which I brought forward need not again be referred to. But one point to which (as I have explained) I attach some importance, was that of obtaining from "E" himself the grounds for altering the form of his fundamental statement, in such manner as to exhibit its insufficiency and weakness. This I am enabled to do as follows:—

When no *reversal* of position of either magnet, coil, or observer occurs,

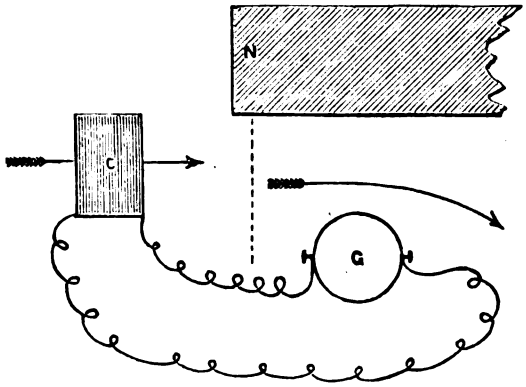
| | |
|---|---|
| (*a*) Adding N lines of force<br>(*c*) „ S „ „ | Current flows in the same direction. |
| (*b*) Subtracting S lines of force<br>(*d*) „ N „ „ | Current flows in the same direction, *i.e.*, opposite to that which obtains under the former conditions. |

Now, when the statement of "E" is put in this (which is the simpler) form, the learner perceives clearly that the effect produced is not dependent upon any (imaginary or "merely conventional") property of the lines of force; and his mind is open to the reception of a *vera causa*, which he may find in the law of Lenz taken in conjunction with the conception of Ampère as to the cause of magnetic attraction. And here I have two very pertinent observations to make. I have said that the "lines of force" explanation is a mischievous one. I have, in point of fact, found it very difficult to remove from the mind of the learner the impression, derived from explanations such as that given by "E," that inductive effect is essentially dependent upon the "north" or "south" character of "lines of force" in action. It is more difficult to unlearn than to learn; and the student of electricity who has unfortunately received a certain kind of preliminary scholastic "training" in the science is a long time before he can realise that the inductive action of a north pole is the same as that of a south pole (when no reversal of position takes place), and that the introduction of the *neutral point* of an electro-magnet within a coil is attended with a *greater* inductive effect than that resulting from the insertion of one of its *poles*. The second observation is that the essential truth of the explanation of magnetic attraction given by Ampère, confirmed as it is by experiments in various directions, appears likely to obtain a fuller recognition as advances are made in the study of the molecular constitution of magnets.

One of my objections to the explanations put forward by "E"—its incompleteness and insufficiency—is, if established, (a point on which your readers must judge for themselves) almost obviously fatal to that explanation. On the other hand, I am bound to admit that its refutation would probably be equally damaging to the explanation put forward by myself. Here, then, we touch one of the real and vital points at issue. According to the law of Lenz and Ampère's theory, a wire when approaching a magnet is traversed by an inverse current, and when receding from the magnet is traversed by a direct current. I do not know of any real exception to this rule. The necessary conditions of magneto-electric or current induction are simply this approach or recession, or the increment or decrement of the inducing current. Now, the theory of "E" "pretends to explain only the inductive effect of a magnet upon a *coil*; and it does this without any reference to the laws which he admits to be "based on eternal truth." His explanation does not include the case of a *simple wire* moving in the vicinity of a current or magnetic pole. The laws in question, however, not only explain, as I have shown, the inductive effect upon a coil, taken as a whole, but indicate, moreover, that certain portions, more particularly, of the wire composing the coil are subjected to a distinct and separate inductive action as they approach and recede from the magnetic poles. The theory of "E," I maintain, is incomplete and insufficient, because it fails to take into account this latter inductive action. It is not my province to supplement his statements by means of any knowledge I may have of the resources of the "lines of force" theory—a theory which, by the way, I may admit to be mathematically useful, whilst

Digitized by Google

regarding it as purely artificial. But any attempt that might be made in this direction by those who are inclined to support his view is rendered nugatory in advance by the fact that he places himself in antagonism to the laws which have been referred to by completely repudiating the idea that any inductive action occurs other than that illustrated by his diagram. Indeed, his contempt for the suggestion that a distinct and detrimental inductive effect occurs in virtue of the approach and recession of wire to and from the poles is absolutely overwhelming. The wires may cut the "lines of force," approach the poles or recede from them; but he will not hear of any inductive effect due to such causes. If my experiment seems to show that the inductive effect in question actually takes place," so much the worse" for my experiment. It is stated *ex cathedrâ* by "E" (writing sometimes in the first and sometimes in the third person) that this experiment has "no scientific value whatever," and that it "is really too utterly unscientific to deserve one moment's attention at *our* hands." But he condescends to intimate that one of his grounds for this slightly arrogant assertion is that in the Gramme machine there is "a powerful S pole opposite the N pole" represented in my diagram—which I will ask the Editor kindly to reproduce here.



Well, supposing a south pole to exist opposite the north pole, in what manner will it modify the result of my experiment? If the coil be at the *same distance* from the south as from the north pole, two equal and opposite inductive effects will be produced upon those portions of the wire which are in proximity to the respective poles; and it may be conceded that these effects, neutralising each other, will not involve in their production any loss of energy. But what will happen if the coil be *very much nearer* to the north than to the south pole? I maintain that one of these effects will disappear, whilst the other remains active, and that the coil, as in my experiment, will be traversed by an induced current, necessarily involving an expenditure of energy. Nor can I admit that the effect in question will be obviated by the presence of an iron ring passing through the axis of the coil, and constituting an armature to the magnet.

It is evident that a point of fact is here at issue, upon which, if "E" be right, I am wrong, and *vice versâ*. I have not at the present moment either a Gramme machine available for experiments to determine this point, or time to devote to such experiments. But, were it otherwise, I should prefer that the experiments should be made by other hands competent to decide upon the question. In taking leave of my opponent for the present, I am anxious to assure him that the truth is of greater interest to me than any personal consideration.

I have intimated that in my article of the 2nd inst. I had other cases in view besides that which was brought into special prominence. In some cases within my experience, persons having very great "pretensions to knowledge" have held views in relation to magnetism and magneto-electric induction which a little discussion (such as that now taking place in the pages of *The Electrician*) would have proved to be entirely erroneous. Any discussion of this nature was, however, declined, on grounds of "scientific reputation." This, perhaps, was prudent; for it must be admitted that "hard knocks" are sometimes given and taken, Mr. Editor, even in your paper. But at the same time the erroneous position was arrogantly maintained. Bearing this in mind, I may have used, now and then, a somewhat strong expression—*liberavi animam meam*—I think justifiably. One case I had in view was in connection with a passage in *La Lumière Electrique* of M. Fontaine. After describing the phenomena produced by the passage of a coil along a magnet which it encloses, the author states:—"If, instead of moving from left to right, as we have supposed, the movement is from right to left, everything occurs as before, with the exception that *the currents are opposite.*" (I have not the original work at hand; but I take the translation of Mr. Paget Higgs, which, if my memory serves me, accurately reproduces the sense of the passage.) Now, the currents are not "opposite"—they are in the same direction whether the movement of the coil be from left to right or from right to left. And yet not only has the statement remained unchallenged, but, as I happen to know, many persons have been ready to support it in the only sense the words will bear, viz.:—that if we obtain "throws" of the galvanometer needle to the *right* and then to the *left* when the movement is in one direction, we shall obtain "throws" to the *left* and then to the *right* when the movement is in the other direction.

In reference to the former of the two questions propounded to me by Mr. Snell; if the space between the poles of opposite name be considerable, he will find that a *direct* current will be generated in the coil as it moves from contact with one pole, and that an *inverse* current will be induced as the coil moves into contact with the other pole. He will thus obtain two "throws" in opposite directions. Of course, if the space between the poles be very small, the effect will be very small also, as when a coil is moved for a very short distance along a magnet. Mr. Snell's second question (which cannot be said to present the case converse to the above) is perhaps best answered by pointing out that the inductive effects are produced by virtually inserting within a coil, and subsequently withdrawing from it, a magnet, *i.e.*, the equivalent of a circular current.

One word to Mr. S. E. Phillips, whom I may term an old friend, though we have never met. If he can realise the idea that heat is a "mode of motion" and that the molecules of all bodies—not being at the absolute zero of temperature—must necessarily be in rapid motion, then I think that the difficulties which prevent him from admitting the real existence of something equivalent to Ampère's circular currents may be removed. But if he cannot accept this view of the nature of heat (which I find it impossible *not* to accept), then I fear we must continue to disagree on the questions of the relation between electricity and magnetism, and the proximate causes of magnetic attraction and magneto-electric induction.—Yours, &c.,

DESMOND G. FITZGERALD.

---

TO THE EDITOR OF THE ELECTRICIAN.

SIR: Through the kindness of Professor S. P. Thompson I have been allowed the use of the Laboratory of University College, Bristol, for the purpose of repeating the experiment described by Mr. FitzGerald in your last issue.

In two particulars the apparatus used differed from that represented in Mr. FitzGerald's diagrams. The coil had no wooden core, only an atmospheric one; and the magnets used had two poles a piece.

The diagrams, which are roughly to scale, will probably be intelligible without explanation. The note of interrogation on the galvanometer in Fig. 7 means that the movements of the needle were uncertain, apparently consisting of a jump first in one direction and then in the opposite direction.

The galvanometer was placed at a considerable distance from the magnet; and before the current from the dynamo was passed through the coils of the magnet, no movement of the coil produced more than a slight oscillation of the needle.

The diagrams seem to show that the efficient distinction between those movements of the coil which produce a throw of the needle to the right and those which produce a throw

Digitized by Google

to the left, does not consist simply in the difference between approach to and recession from the magnet pole.

Figs. 7 and 8 are somewhat anomalous; but when a compass needle was moved about near the N pole it took up successive positions, the directions of which are indicated by the curved lines drawn in Fig. 9. When these are added to the diagram it becomes apparent that a movement of the needle to R accompanies an increase in the number of those lines which, drawn from the N pole of the magnet, enter the

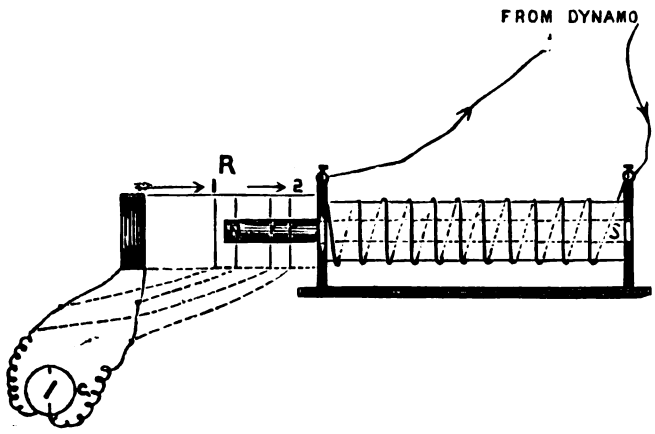


Fig. 1.

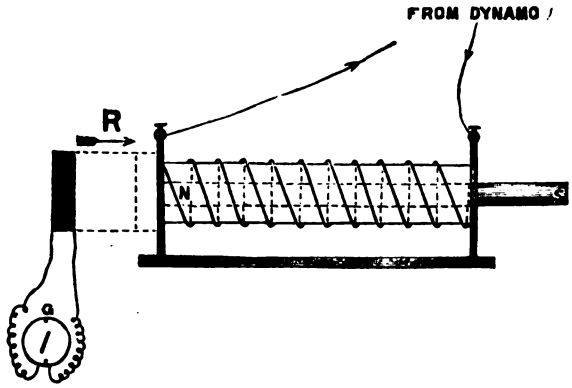

Fig. 2.

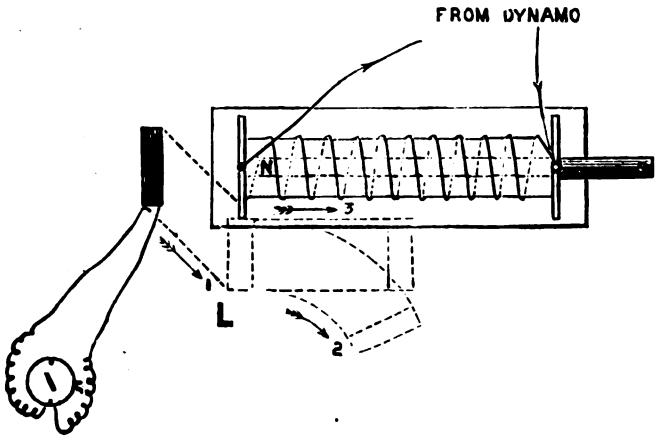

Fig. 3.

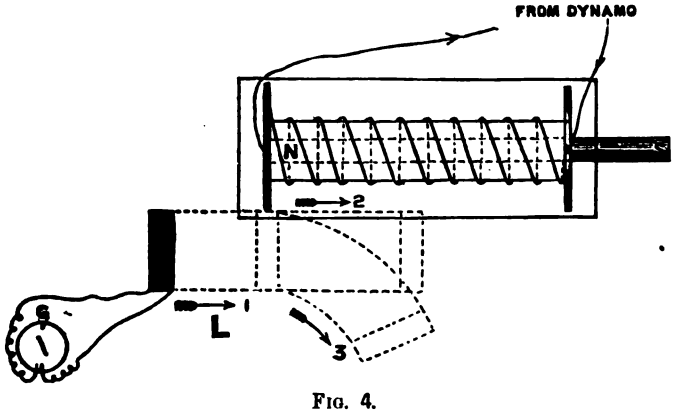

Fig. 4.

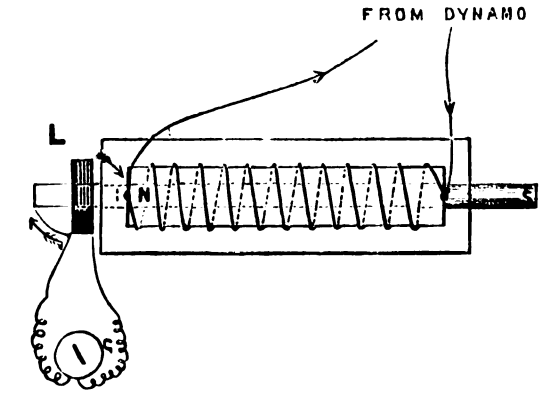

Fig. 5.

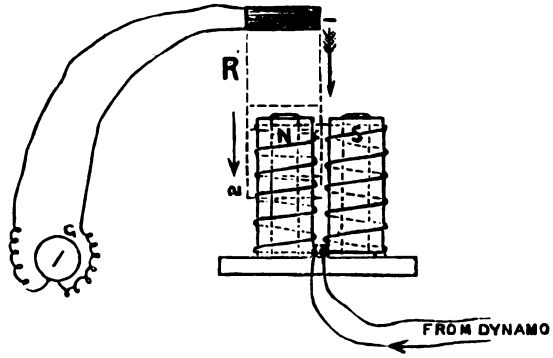

Fig. 6.

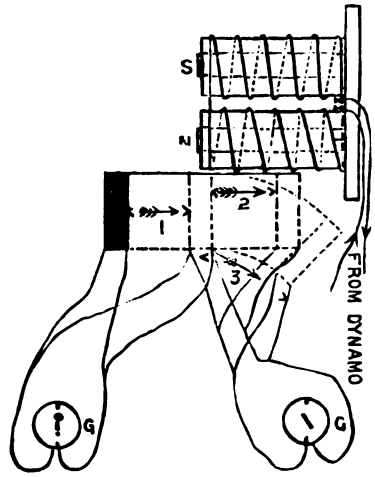

Fig. 7.

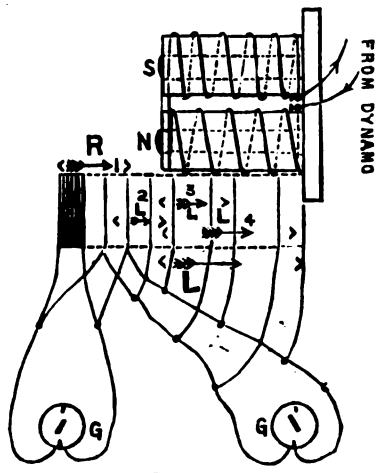

Fig. 8.

Digitized by Google

coil through its right-hand face, and a movement to L accompanies a decrease in the number of the same lines, and also accompanies an increase in the number of those lines which, similarly drawn, enter the coil through its left-hand face.

This seems to me to be an illustration of the truth of the theory commonly called Maxwell's. It is quite consistent with the law of Lenz—as indeed it can hardly fail to be, both being deductions from the principle of conservation of energy.

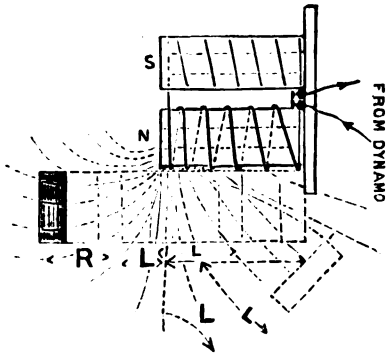

Fig. 9.

Evidently the current R resists the attempt to increase the "flow of force" through the coil, while the current L resists the attempt to decrease that "flow of force," or to increase a "flow" in the opposite direction,

Is not all this most neatly and accurately summed up by Maxwell thus ?—"Any displacement of the circuit" (carrying a current) "will be aided or resisted accordingly as it increases or diminishes the number of lines of induction which pass through the circuit in the positive direction."

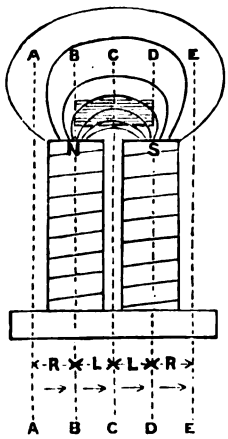

Fig. 10.—The coil was moved from the position in which its axis coincided with line A A into the position B B, thence to C C as shown, thence to D D, and thence to E E. The letters R and L refer to the movements of the needle.

I do not quite see why the last experiment described by Mr. FitzGerald is called an "*Experimentum crucis.*" The results, as they are given, are precisely what Maxwell's theory would lead one to expect. For to poke a N pole into a helix in the positive direction is to increase the number of lines of induction which pass through the helix in a positive direction; while to poke a S pole into the same helix in the opposite direction is also to increase the number of the same lines; hence the current will be the same in both cases.—Yours, &c.,

W. M. Moorson.

---

TO THE EDITOR OF THE ELECTRICIAN.

Sir: I have read with much interest the letters regarding the theory of the "Gramme machine" which have been from time to time printed in your columns. With respect to Mr. Desmond FitzGerald's article on the above subject in your last issue, in which he attacks the hitherto accepted theory with regard to the lines of force, I wish to point out some errors into which he has fallen. He takes offence at the distinction "north lines of force" and "south lines of force." There is, however, no need for this distinction if we simply regard lines of forces as lines of force proceeding from a N pole either to a S pole or going off to infinity, and *s* lines of force as lines of force either coming from a N pole or from an infinite distance.

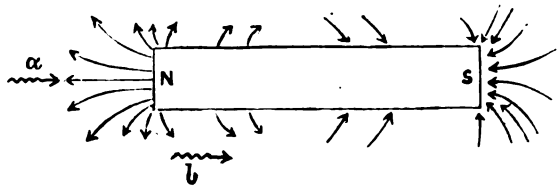

Fig. 1.

Thus, a field of force would be drawn something like Fig. 1.

With regard to Fig. 3, on page 280, the "unknown fact" we are shown by this experiment, instead of contradicting the theory, really confirms it. He has, in fact, in the first case moved the coil in a contrary direction to the lines of force, and in the second along the lines of force, thus producing currents circulating in opposite directions round the coil. Fig. 4, on page 281, may be simplified in Fig. 2.

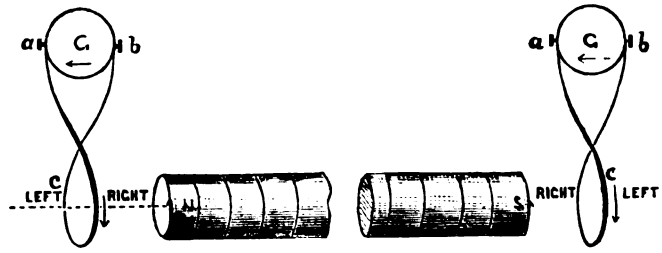

Fig. 2.

Now, if Mr. FitzGerald face the N pole in one instance and the S pole in the other, the direction in which the coil is moved (which it is necessary to consider even in finding the direction of the current from the law of Lenz), he will see for himself that the currents through the coils are not in the same direction; but that the seeming paradox is due to a slight difference in the way the galvanometer is connected up in the two cases.

Mr. FitzGerald wishes to know why the cutting of lines of force by a conductor, or their passage through a coil, should produce a current; it is really their surrounding the wire that produces the current.

We know from the experiments of Mr. Smith (see *Electrician*, Vol. XII., p. 18) that lines of force take a longer time to pass through metals than air—that is their velocity is less in a metal than air. Now, if a coil of metal be suddenly pushed up to a pole, it will push the lines of force out of position for a moment; but after a short time they will pass through the coil and the field will be once more in equilibrium.

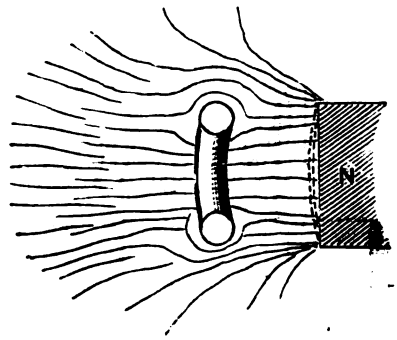

Fig. 3.

A section of the field across the dotted line in Fig. 2, taken immediately after the coil has been pushed into the field, would be something like Fig. 3.

The magnetic lines of force surrounding the coil, according to

Digitized by Google

Maxwell's theory, constitute vortex rings in the æther; the result will be a stream of æther round the coil.

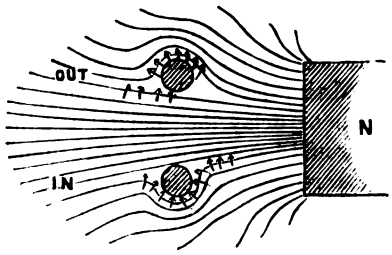

Fig. 4.

Fig. 4 is a very poor representation of this. If we suppose the vortical motion of the æther which constitutes the lines of force to coincide in direction with that of the amperian currents (which it would do if a flow of the electricity represents a flow of æther), the current then in the coil would be in an opposite direction—from which we can deduct the law of Lenz.

Now, after this momentary current has passed round the coil, the lines of force begin to pass through the coil, and since their vortical motion is less within the metal, the pressure produced in the æther, at right angles to their direction, will be less through the coil, and the coil will, so to speak, concentrate the

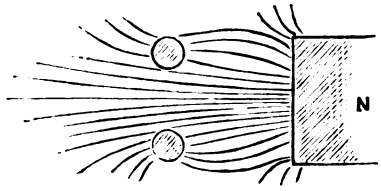

Fig. 5.

lines of force, which will again diverge after passing through the metal something like Fig. 5.

With regard to Mr. FitzGerald's "Physical Theory," it appears to me to be a simple rule deducted from two well-known and simple laws; but I cannot see how this rule is going to supplant Maxwell's theory.—Yours, &c., R. P. F.

P.S.—I have not run through the case of withdrawing the coil from either pole, which is more difficult, but can be similarily explained. If we suppose the lines of force to be replaced by indestructible pieces of (perfect) elastic, which fill up the whole space, and have a vortical motion, the case will be much simplified.

[R. P. F. has not complied with our rule in sending his name and address, and is not alone in default. We have not followed this well-known rule simply as a matter of form, but in order to know our contributors, and to be able to avoid certain well-known "tricks of trade" that seem to us objectionable. We have inserted this and another letter because their *bonâ-fides* are evident; but, generally, letters unauthenticated are consigned without hesitation to the waste-paper basket.—Ed. *E.*]

## A PECULIAR ACTION OF CARBON.

TO THE EDITOR OF THE ELECTRICIAN.

Sir: Using a high resistance made by rubbing lead pencil between two clamps on a piece of ebonite, for the purpose of reducing the deflection of a dead beat reflecting galvanometer used for measuring the E.M.F. at binding screws of an electromotor, I observed that the deflection before running the motor was 200deg. on scale. After running the motor it had risen to 250deg., showing that either the E.M.F. of the battery had risen, which was unlikely, or the resistance had fallen. This led me to investigate the matter, with the following results:—In Fig. 1 the galvanometer is in circuit with battery key 2,20,000 ohms (to reduce deflection), and two small carbon sticks, *a a'*, which rest firmly on a small heap of plumbago, P, The normal deflection with five gravity cells is 10deg. on scale. Opening and closing key 2 or reversing the battery has no effect in increasing the deflection, but after rapidly opening and closing key 1 a few times, which short circuits battery, galvanometer, and 20,000 ohms, through a magnet, *m*, of 100 ohms, the deflection rises in some cases to 150deg., showing the resistance between *a a'* to have become 1-15 of the original resistance. If left undisturbed it will remain so indefinitely, but if it receives any jar or vibrations it rises to its original resistance. I also tried

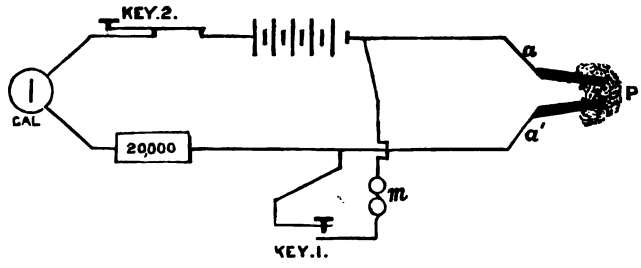

Fig. 1.

using the two carbon sticks in microphonic contact, as in Fig. 2. The galvanometer was shunted in this case to reduce the deflection. On opening and closing key 2, no alteration of resistance was observed, but after opening and closing key 1 a few times (completely short circuiting galvanometer and battery), the resistance was found to have fallen greatly, and by substituting a resistance box for the carbon sticks, the

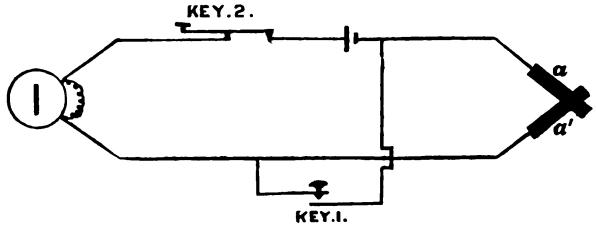

Fig. 2.

original deflection reproduced showed the resistance to have been about 200 ohms, falling after closing key 1 to 20 ohms. Only one cell could be used in this experiment, as otherwise there was a continual chattering at the carbons, and the spot was unsteady. With a magnet in circuit with key 1 the change was not so large. It would be interesting to see if finely divided metals would behave in the same manner, but I cannot procure the materials in a fine enough state to come to any conclusion.

I am unable to account for the phenomena, as the opening and closing of key 2 shows conclusively that it is not the effect of heat, and experiment 2 shows it cannot be due to an extra current of high E.M.F. from the magnet, as it works better in this case without a magnet, while in the first it is almost essential.—Yours, &c.,

Chas. Cuttriss, Mechanician.

Anglo-American Telegraph Company, Duxbury, Mass., Jan. 24, 1884.

## PROFESSORS AYRTON AND PERRY'S FORMULÆ.

TO THE EDITOR OF THE ELECTRICIAN.

Sir: There is only a mistake of one letter in the above formulæ as printed in the *Journal of the Society of Telegraph Engineers*, which is in the second one quoted by your correspondent, viz:—

$$x' = V - (c + c')(R + r') - C'(R' - R)$$

(the last letter in the last factor being corrected).

The formulæ are easily understood if it is borne in mind that the potential absorbed by the first consumer, plus that lost on the main lead between *m* and *n*, is equal to the potential absorbed by the second consumer, plus that lost on the lead between M and N.

Thus, $x + c(r - r') = x' + c'(R' - R)$.

The current supplying both consumers only traverses the resistances $R + r'$.—Yours, &c.,

H. D. Wilkinson.

School of Electrical Engineering, Hanover-square.

## IMPORTANT NOTICE.

*** All communications should be sent to our new offices, 1, Salisbury-court, Fleet-street, E.C., where *The Electrician* will in future be printed and published.

The affairs of electric lighting and other electrical enterprises have now reached such an important stage, that we feel compelled to give practically verbatim reports of meetings, though to do so is to crowd out of our columns many interesting articles and a number of letters.

## THE BRUSH ELECTRIC LIGHT COMPANY.

The proposition to reduce the capital of the Anglo-American Brush Electric Light Corporation by one half seems to have occasioned little surprise among the shareholders, and has been acquiesced in with what some people may call resignation, but which others will regard as enthusiasm. Such a scheme as that sanctioned at the general meeting reported in our last issue is rarely put before any body of shareholders. When matters come to a pitch at which an heroic remedy of that kind becomes one of two alternatives, the other, namely liquidation, is usually the one resorted to. That the directors of the Brush Electric Light Company have proposed, and the proprietors agreed, to go on with the business, confessing a loss of capital which in ordinary circumstances would mean bankruptcy, is proof that they have unabated confidence in the future of the electric light, and especially in that system which is worked by the Brush Company.

On the whole we cannot but compliment the directors on their courage, and the shareholders on their good sense. This was a case where to delay the inevitable admission of comparative failure would have been to court complete disaster by and by. With a reduced capital—that is to say, with a self-denying agreement to call what was once £10 only £5 now—the management hope not merely to pay their way, but to earn a dividend. It is the fate of most pioneers to suffer a similar loss, sometimes less but often greater, in order that others who follow may succeed better; and whether we call it a lost cable, an unremunerative railroad, or an abandoned mine, the result is the same—either the capital is watered down, or it is frittered away, or it is boldly wiped off the books. The Brush Electric Light people have wisely adopted the latter course, and whatever may be the final outcome of their conduct one thing will always be said for it, that it was honest and straightforward. If the shares are on the market people will know what they are invited to purchase. They will not imagine they are securing the prospective value of a ten-pound note, when, in reality, it can never represent more than half that amount.

Then, again, it may be said the particular company in question is able to afford to make this great sacrifice. If we could be sure that the people who reaped all the proceeds of the lucrative business done in the way of selling concessions are the same set of people who now submit to having half their investments confiscated, we might feel perfectly easy as to their peace of mind, and it would go a great way towards explaining the lamblike patience with which they have submitted to be shorn. A splendid harvest has been reaped by somebody, and we sincerely hope it has been garnered by none other than those who now have to content themselves with a business of quite another kind—namely, the business of electric lighting conducted on commercial principles, and with a view to earning a dividend by actual work performed. Mr. Hammond animadverted on the policy of the old Board of Management, who had distributed in dividends £230,000, and wanted to know whether the then directors could not be "induced to disgorge" the money they took. We never heard of anybody, whether directors or shareholders, being "induced" to perform that unpleasant operation except by compulsion; and from what the chairman said in reply it does not appear that compulsion is either expedient or lawful. There was, he said, nothing against the old Board from a legal point of view, and its policy had received the approval of the shareholders. Naturally; when a quarter of a million is offered for distribution it is not in human nature, certainly not in the human shareholder, to withhold his approval. He takes what he can get, and if he is wise he then takes himself off. There appear to have been a good many wise men connected with the Company in the time of the "old Board."

The action of the new Board, if cordially supported by the shareholders, is not likely to provoke much adverse comment from outside. The Anglo-American Brush Company is associated in the minds of the public with the earliest, most numerous, and most successful of electric lighting installations. Its name is familiar almost everywhere, so much so that there can no longer be any need for that species of advertisement which to a large extent is responsible for the disappearance of half the Company's capital. All they have now to do is to push their trade as business men should. They have improved their prospects by adopting incandescent lighting as part of

Digitized by Google

their programme, a branch of business which we have always said promises the best return in the long run. The Company's prestige is great, and will not be impaired by what has taken place just now. If there is profit to be made out of electric lighting, and we repeat our conviction that there is, the Brush Company is as likely to make it as any other—perhaps, under the changed conditions, much more likely.

## FRANK IVES SCUDAMORE, C.B.

If Mr. Scudamore had remained in the service of his native country the news of his premature death would have created something like a sensation of national loss. As it is, the promise of a brilliant future terminating in the inglorious and unprofitable service of an Oriental Government excites only sadness and commiseration. Those who knew him personally, even his humblest subordinates, entertained for Mr. Scudamore feelings of friendship and loyalty to which they would now have gladly given expression had not their object been an exile in a foreign land. Nearly ten years have elapsed since he bade his country adieu for ever; and although the reading public have occasionally been reminded of him by contributions to journalism which were easily recognised as his, he has been practically dead to English life since 1875, and his admirers can pay no more substantial tribute to his memory than to recount their reminiscences of his genius, his geniality, his kindliness, and his marvellous capacity for work. That they can do no more than this is not their fault. His was the career of a great man rudely cut short by an evil fortune over which nobody had control but himself, and the consequences of which perhaps nobody lamented so little as he.

It has been the fashion of late years to attribute the commercial failure of the telegraph since its acquisition by the State to the excessive price paid as compensation to the various companies. The price was indeed great, but so was the actual value of the property to those who owned it, to say nothing of its prospective value. Respectable Governments cannot afford to be niggardly—at least such was the recognised doctrine of this country fourteen years ago, before theories of confiscation had found a place in the political creed of its rulers; and at the time of which we are speaking it is in the highest degree improbable that better terms would have been obtained for the Government than those which Mr. Scudamore negotiated, and which provoked no serious criticism when completed. Whether Mr. Scudamore could have made the telegraphs pay interest on the original capital expended may be a question open to discussion, but if any man could have accomplished that feat the then second-secretary of the Post Office was that man. His presence at the head of affairs just now would have proved invaluable for solving in a decisive manner the question of the tariff on a sound and rational basis—a task apparently which the present administration find by no means so easy as they fondly, and it seems to us rashly, imagined eight months ago. Be this as it may, however, it will be universally admitted that for the prodigious efforts demanded in the transference of the business of the companies to the department of the Post Office Mr. Scudamore was the one and indispensable instrument. His splendid talents for organisation, his aptitude for mastering novel and technical details, his personal influence in creating a staff of ever willing workers, and the example he set them of energetic, never-tiring industry, were qualities which it is the rare fortune of Governments to command at moments when most needed. Looking back at the period between the winter of 1869 and the autumn of 1870, it is hard to imagine that the transfer could have taken place had there been no Mr. Scudamore to plan and direct the transaction. This, at all events, was the verdict of the men who had hitherto controlled the affairs of the several telegraph companies. To make Mr. Scudamore's acquaintance was to instantly recognise a man of commanding abilities, and to feel confidence in his final triumph over the difficulties which necessarily surrounded a work of such magnitude. His success was assured from the first, and if his precautions against failure erred rather on the prudent and expensive side, his successors, at all events, who are responsible for the financial troubles of the Parcels Post, have no right to reproach him on that score.

After adroitly adjusting the wages dispute, which was the one serious peril of his administration, but which was due to no lack of sympathy or good offices on his part, Mr. Scudamore betook himself to raising the telegraph staff—now under his sole control—to a level which he conceived to be necessary for the efficient performance of their duties. The Society of Telegraph Engineers was established in the year following the creation of the Government telegraphs, and was greatly encouraged, if not actually formed, at the suggestion of electricians enjoying Mr. Scudamore's confidence. From the first he saw the great service such a society might render to his department, and he lent it the cordial help of his pen, his purse, and his presence, so long as he remained in this country. In 1873 he became its president, more by way of stamping it with his approval and encouraging others to follow his example than from any professional fitness for the post, except as chairman of its meetings—a part he was able to play under any conditions whatever with a felicity and grace peculiar to him. His speech from the presidential chair, which can be read in one of the early volumes of the society's *Journal*, is a model of that conciseness, precision, and mastery of English for which he was noted, and which would have made him famous either in politics or in letters had he chosen to follow them as a profession. "I had hoped," he said, "that during this year, as during last year, this chair would have been filled by a man of scientific eminence. . . . . Such a president you have had, such a president you should always have, but, unfortunately, such a president you cannot have in me. It has been my lot on more than one occasion to be placed, by the kindness and partiality of friends, in positions for which I have not the proper qualifications. For instance, I cannot row. I very much doubt if I can sit straight in a boat, and yet I am president of one of the best rowing clubs on the Thames. I cannot shoot—indeed, I cannot see above twenty yards in front of me, and yet I am the honorary colonel of a rifle regiment of no mean reputation. And now Fate, with equal irony, makes me president of your society, though I know little or nothing of telegraphy." The practical object he had in view beyond that of benefiting the engineers of the Postal Telegraph Department by bringing them in contact with the engineers of other services was "that the great body of persons who are engaged in the practice of telegraphy throughout the country may learn that their occupation has attained to the dignity of a profession . . . . to make them proud of it, to make them desirous for improvement, and to awaken in them a spirit of inquiry and a thirst for further knowledge . . . . and that from this awakened curiosity improvement and development may proceed."

The society's present list of members, including as it does a very great number of Postal Telegraph *employés*, is sufficient commentary upon its second president's wisdom and foresight. Very soon afterwards Mr. Scudamore had, however, to sever his connection with the Post Office, as well as with the Society of Telegraph Engineers. He excelled in all business matters, except, unhappily, his own, and pecuniary embarrassments having compelled him to seek and commute his pension in 1875, he left this country to take charge of the Turkish Postal Department in Constantinople. Of his services to the Turkish Government in this position we can feel quite sure; how they were rewarded we can only conjecture from the highly probable statement recently made by the *Globe*, that he died in embarrassed circumstances owing to his inability to obtain arrears of salary from the Turkish Government. His public memory will ever be associated with that great undertaking which transferred the telegraphs of this country to the keeping of the State; but by those who had to work with him he will be remembered as the most genial of men, the best of companions, and the kindest of masters; and on whoever had the good fortune to come in contact with him he has left an indelible impression that he was one of the ablest and most gifted men of his time.

## THE SPEED REGULATION OF PRIME MOTORS FOR DRIVING DYNAMO-ELECTRIC GENERATORS.

BY T. H. SEYMOUR HAWKER.

The speed of prime motors—notably steam engines—has hitherto, owing to the imperfections of so-called automatic governing appliances, been exceedingly unreliable, and, in addition to liability to vary by any considerable alteration of load, has been very little under control for purposes of adjustment.

While the developments of electrical industry were limited to very small installations, not involving any great range of work variation, these faults could generally be neglected, and the ideal conception of a perfect motor seems to have become associated with a constant and invariable speed under varying conditions.

In order to adapt this constant speed to the requirements of work on a large scale, involving a considerable range of variation, it was found necessary to resort to complex, difficult, and expensive arrangements of compound winding in arc field coils of the generators, in order even very approximately to attain the desideratum of a constant electromotive force for multiple arc work or a constant current for series work. The practical success of this method of evading the difficulty is, moreover, doubtful at least, and is greatly marred by the reaction of load fluctuations on the engine, producing variations of speed which no governor at present in the market can efficiently neutralise.

Either factor, if the electric energy flow, which it is necessary to keep constant, is affected by the speed, of which, indeed, it is in all cases a definite and determinable function, dependent on the nature of the dynamo machine. It is only to be expected, therefore, that any sudden lurch in the engine, caused by a quick alteration of its work, and which even an almost theoretically perfect governor will fail to prevent, must cause a variation in current, always highly objectionable, and often dangerous.

It is clear then that the *speed* must be under command to give anything like a satisfactory result on the large scale.

The idea, then, follows, as a logical issue, Why not dispense with the unnecessary complications in the generator, and trust entirely to the speed to give the constant conditions?

This can easily be done by making the engine or prime motor speed a direct function of either the E.M.F. or current in the mains.

In order to realize this condition, the writer designed, as early as 1879, an electrical governor for application to the throttle, or expansion gear, of steam engines, and by which the speed was made absolutely adjustable for purposes of regulation, and automatically governed by the electrical function which it was desired to keep constant.

The speed of the generator becomes in this method variable on either side of that number of revolutions which are found to give the normal value; the negative position of variation being proportionate to the defect of excess of the constant electrical factor, or that function of the latter expressing its relation to the speed.

The system is naturally equally applicable to alternating current machines, and enables these to be run with complete compensation for the varying ratio of internal and external resistances which is inseparable from a public supply circuit or a large incandescent installation, and which usually causes a great variation of E.M.F. at the lamp terminals.

It ought to be quite practical, with this system and a separate excitation of field magnets, to start running, with a single lamp, and, without any attendance to engine or generator, increase the number of lamps to the maximum without a fluctuation in their individual brilliancy.

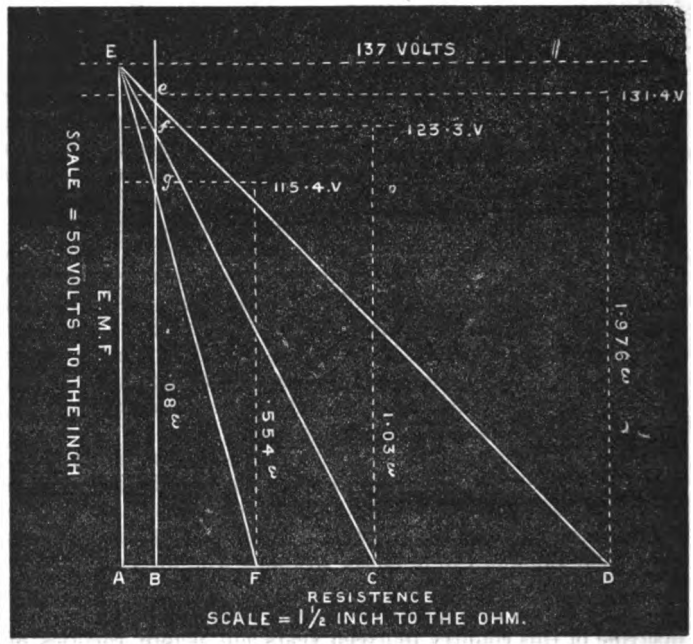
Let us take as an illustration of the application of this arrangement to a multiple arc circuit the following diagram, obtained from a recent example afforded by a large incandescence installation.

The vertical ordinates represent E.M.F. on a scale of 50 volts to the lineal inch. The abscissa represents resistance of circuit, and is the sum of the line A B representing permanent resistances, including cables and internal resistance of generator, and the line B C representing resistance of lamps—the scale being 3 inches to the ohm.

The dynamo gave an E.M.F. of about 137 volts, as shown by ordinate E A, and 123 volts of this were needed to supply the lamps with ·52 ampere each.

The resistance of 250 lamps, while running at about 23 candle-power, in simple multiple arc, was ·948 ohm, and the circuit about 9 per cent. of this. The ordinate $f$B shows the nominal E.M.F. at lamps, and the fall of potential is shown by the line E$f$C.

If we cut out half of the total number of lamps, thus doubling the aggregate resistance, the E.M.F. falls far more gradually, as shown by the line E$e$D, while the value at the lamp terminals increases by the amount $fe$ to 131·4 volts, which gives a very excessive current, endangering the lamps if at all weak.



Again, by doubling the number of lamps in circuit, and thus halving their aggregate resistance, the E.M.F. at the lamps is reduced by the amount $fg$ to 115·4 volts, and they lose all their brilliancy.

With a series circuit these effects are naturally still more evident and deleterious, and it becomes evident that no form of compound winding could correct, except very approximately, for a short range on either side of the normal resistance.

Moreover, compound winding must necessarily decrease the duty of a machine—I mean the ratio of electrical output to gross weight—and thus render larger, more costly, and clumsier machines necessary. The electrical system of speed governing, on the contrary, controls with one apparatus both prime motor and generator, the latter of which may be of any of the known types, while discarding the usual imperfect and clumsy devices of varying the exciting current by hand, or adding useless resistance in the main circuit.

I hope to have an early opportunity of giving full details of my own apparatus, but wish meanwhile to call attention to the theory of this method of compensation, which I may summarise as the intentional variation of driving speed, in such a manner as to maintain a constant relationship between the activity of the generator and the work to be done, to increase the activity by increased speed when insufficient, and decrease by decreased speed when excessive.

---

DOMESTIC LIGHTING.—At the next meeting of the Royal Institute of British Architects, on the 18th inst., a paper will be read by Mr. Killingworth Hedges, C.E., on the "Electric Lighting of Houses, and the Precautions to be Adopted in its Introduction."

## THE DIRECT UNITED STATES CABLE COMPANY (LIMITED).

The thirteenth ordinary general meeting of this Company was held at the Cannon-street Hotel, on the 8th inst., under the presidency of John Pender, Esq., M.P.

The SECRETARY and TRAFFIC MANAGER (Mr. J. W. Fuller) having read the notice convening the meeting, the report of the directors was taken as read.

The CHAIRMAN said: Before making any remarks on the past half year, I may just very briefly refer to the figures of the revenue. The revenue of the half year ended December 31st last was, after deducting outpayments, £73,472 12s. 7d., and the working and other expenses £21,824 4s. 5d., leaving a balance of £51,648 8s. 2d. as the net profit of the half year, making, with £1,852 7s. 11d. brought from the previous half year, a total of £53,500 16s. 1d., which has been appropriated as follows:—Interim dividend of 5s. per share to 30th September, £15,177 10s.; interim dividend of 5s. per share to 31st December, £15,177 10s.; amount set aside to reserve fund, £19,621 7s. 7d.; balance carried forward, £3,524 8s. 6d. That makes a total of £53,500 16s. 1d. The revenue shows a decrease of about £4,000 as compared with the corresponding period of 1882, when the tariff was the same. This reduction is owing to the general depression of trade, referred to in the last report, and which still continues. The working expenditure again compares favourably with that incurred in the past, the expenses at stations showing as reduction of about £2,000, due principally to the existing arrangement on the American side, which were not in operation in 1882. The expenses in London are about £120 less than in the corresponding period of 1882. On the whole the expenses show a reduction equal to about £2,000 per annum. The reserve fund has been increased, by transfer from the revenue account and by interest on the investments, to £340,000. The present market value of the Company's investments, which stand in the accounts at a cost of some £351,000, is about £360,000, or an increase of, say, 3 per cent. on their cost to the Company. The resolution I shall propose will be as follows:—"That the Report of the Directors, dated 28th January, 1884, together with the Statement of Accounts for the half year ending 31st December, 1883, annexed thereto, be, and the same are hereby, adopted."

Mr. WILLIAM FORD: I beg to second that.

The CHAIRMAN: That, gentleman, is the resolution I shall ask you to pass, but before doing so I will make a few further remarks. I think I have shown you that the past half year has, upon the whole, been satisfactory. When I addressed you twelve months ago, I reviewed the position of submarine cables, and spoke as to their value and earnings. Since that time, as you are aware, there have been many rumours of opposition, and of new cable companies being formed, but looking to the fact that we have cables in the Atlantic (more particularly since they have been duplexed) far in excess of traffic requirements, I thought that, at all events for a time, we should have enjoyed some little repose. In this I have been disappointed. You will, therefore, naturally expect me to say something as to the coming opposition, and how far it is likely to affect our interests. I think, gentlemen, at all events, that it is better on occasions like these that there should be confidence shown by directors in their shareholders, and in doing that I am also satisfied that we secure the confidence of our shareholders in a degree which encourages us in the work we have in hand, namely, the protection of your interests. As a rule, I have no right to deal with anonymous newspaper paragraphs, and therefore I attach little importance to the statements which appear from time to time to the effect that new cables are to be laid—the papers in America stating that the capital has been found in England, while the statements in the English papers are to the effect that the capital will be found in America. But when I learned from unquestionable authority, viz, from Mr. Garrett, and also from Mr. Bennett, that they contemplated laying cables to work in connection with the Baltimore and Ohio telegraph system, I naturally looked upon this as meaning business, as both those gentlemen were perfectly able, from their position, and from the means which they might command, to do anything they chose in that direction. I, however, knowing Mr. Garrett, gave him, at his request, some detailed information as to the probable returns at the rates which they intended to charge upon the capital he proposed to invest in the undertaking. I gave Mr. Bennett the same information, and I believe that Mr. Mackay has also had an opportunity of perusing the same document. Mr. Garrett, for reasons best known to himself, does not seem to be connected with the present combination. I assume, therefore, that Mr. Mackay has taken the place of Mr. Garrett, and that there can be now no mystery about the business, as we have a letter published by Mr. Mackay in the *Times* of the 23rd January, which letter must now form the basis of my remarks. Probably some of you may not be aware who Mr. Mackay is, but I may say that he is a man of very great wealth, very great energy, and, I believe you will all admit, very great courage, to put so much money at the bottom of the sea as he now proposes to do. Mr. Bennett is equally enterprising—his name is probably as well known in London and Paris as it is in New York—he is the proprietor of the world-wide known paper the *New York Herald*, and it is, I believe, a source of very large income to him. You now know who these men are with whom we have to deal. Mr. Mackay states in his letter that they have ordered two cables. He was called upon to make this statement on account of some sneering remarks appearing in certain newspapers, which remarks he presumes must have been put forward by professional promoters of companies or by persons interested in existing cable companies. I wish Mr. Mackay to understand distinctly that, so far as the companies in which I am interested are concerned, we have never dreamt of sneering at Mr. Mackay or his gigantic enterprise, however much I may question the judgment which prompted it. But there is another remark in his letter—he calls it a "big business." No doubt it is, but the question for us is how far this "big business" is going to affect us. Whether it is to be worked at a profit or loss is Mr. Mackay's business, but I think I have a perfect right to draw attention to another paragraph in his letter, where he says that his object in founding this new trans-Atlantic Cable Company is that he considered the time had come to give the public on a permanent basis a somewhat cheaper, and at the same time, a thoroughly reliable and prompt cable service. Now, the only inference to be drawn from this paragraph is that there is not existing at the present time a permanent, reliable, and prompt cable service. Now, what are the facts regarding the existing cables? I believe the average time for transmission of our commercial messages is under twenty minutes, and a very large number of messages are transmitted under five minutes. I believe, I may say, without fear of contradiction, that during the last twelve months we have had only one complaint of a message being delayed (and that message was only delayed about one hour), and that delay arose from our land lines being interrupted by a gale. I am speaking here as regards the Direct Company, but I believe the Anglo-American Company is in every respect as careful and as successful in the transmission of messages as the Direct Company is. I think these facts clearly show that the existing companies, who, by the establishment of this system, have done so much to promote commercial intercourse between England and America, have done and are doing their work well, and I believe I may safely say that they will command a large amount of the support of the telegraphing public. And why? Because we have hitherto done our work well, and because we have eight cables. I think it is impossible that any cable company possessing only two cables can ever successfully compete, in commercial interests, with those who possess eight cables. That is a fact I wish you to bear in mind, as it is an enormous fact in connection with the value of your property. Now, as to the rate being too high, we have had no complaints from the general telegraphing public, and the comparatively modest dividend we pay shows very clearly that the rates are not more than sufficient to maintain the efficient service which we desire to continue, and shall as long as we remain in charge. It is said that the reduction of rates would increase the traffic. We have tried the 1s. 6d. rate, we have tried the 1s. rate, and we have tried the 6d. rate; but it is a remarkable fact that at the lowest rate the increase in the number of messages is small compared to the loss sustained; showing clearly that this great system is dependent upon important commercial transactions, and that the elements of speed and efficiency are of greater moment than the question of cost; because so thoroughly have the merchants codified their business communications that upon the whole the expense of telegrams is insignificant even upon comparatively small commercial transactions. That is a very strong position for this Company to occupy. I think I may also point out that as the cables already in the Atlantic are equal to carrying three times the amount of traffic which is offered to them, placing further capital in cables will not tend eventually to reduce the cost of telegrams, if it is expected to get a return upon the additional capital invested. My opinion, therefore, is that such a venture as Mr. Mackay and Mr. Bennett have entered upon is not well timed in the interests of the public, nor can I see that it can be for their own good if they are looking to receive a fair return upon their investment. In a great and grand country like America—I visited it myself two years ago—they could have found many investments which would have given them I may say, without hesitation, four times the amount of money they are ever likely to get out of their Atlantic cable venture. There must, therefore, be some reason other than the money consideration which has induced these two gentlemen to go into this, as they say, "big business." I strongly suspect, from the paragraph which precedes Mr. Mackay's letter in the *Times*, that Jay Gould has something to do with their action. I mean that no doubt there is a great deal of jealousy among these rich men in America, and their desire now, I presume, is to emulate that great financial magnate. Another paragraph in Mr. Mackay's letter states that "since Mr. Jay Gould became master of the Western Union Telegraph Company, and in that capacity made an alliance with the controllers of the existing system of Atlantic cables, the desire to escape from the necessity of using lines even indirectly controlled by Mr. Gould has been growing strong in the United States." This is not strictly accurate, because at the present moment we have an independent office in New York connected with two of our cables, and this office is entirely free from the control of Mr. Jay Gould. One of the principal objects of my visit to America was to satisfy the American public that that gentleman did not control the Atlantic cable system, and, as a result, the independent office at New York was opened, which I repeat is entirely and completely free from any control of Mr. Jay Gould. Therefore there is no excuse on this point for the action of Mr. Mackay and Mr. Bennett. Mr. Mackay then goes on in his letter to say that "Owning the cables ourselves, and not being required to satisfy the wants of small shareholders, who, having but small capital at their disposal, are obliged to expect quick returns and clamour for mercy for their 'one little ewe lamb,' we are in a position to take our stand and defy all attempts at coercion." That is a very grand position for them to take up. I, however, strongly suspect that in the end their ewe lamb will be eaten. This paragraph leads me to look at the list of shareholders of the Company which is under our particular guidance. We have in this Company 1,353 shareholders—out of that number 357 are ladies, and there are about the same number of clergymen. There are many names appearing on our register as the holders of two or three shares each, and after leaving out a few large holders of shares, the average holding is about 25 shares. I believe it is the same with the Anglo Company. They have 6,000, or more than 6,000 proprietors, and I have no doubt that there are proportionately as many ladies and clergymen in that company as there are in ours. When we took charge of this Company there were only about 600 shareholders, now there are, as I have just stated, 1,353, and the number is steadily increasing. Now I think Mr. Mackay

Digitized by Google

will agree with me that it is my duty and the duty of those associated with me to take care that the interests of our "ewe lambs" are fairly protected, and I cannot but observe that he might have employed his money to give him a very much larger return, and much more satisfaction, than in attempting to come into our pasture, in which our "ewe lambs" feed, without any prospect of in any way getting fat upon it himself, but simply taking away a portion of that which, we might almost say, legitimately belongs to us. I say that he has come into a Company who have been the pioneers of this telegram system to America; and, probably, there are no body of shareholders in any company in England that have done a greater amount of good in promoting friendly intercourse—I would say human progress—throughout the world than those who have supported Submarine Telegraphy. He comes in deliberately, without any object of gain to himself, as there is no gain in it, but to try and rob our "ewe lambs" of some of that pasture which they are so fully entitled to enjoy. However, let us see what the result will be. I have no hesitation in saying that the Direct Cable Company's position will be very little, if at all, injured by this competition. The rapid mode of communication by those grand steamers between Liverpool and New York, and which we might almost term ferry-boats, tends to increase our social and commercial intercourse with America. This intercourse almost necessitates the Press doing something more than they have hitherto done in the way of telegraphic news, and, as Mr. Bennett himself remarked, he could pretty well employ his cable in the Press enterprise even if he did not get a share of the commercial traffic. Now, I want to show you that if Mr. Bennett and Mr. Mackay have gone into this venture simply for the purpose of becoming what I will call "popular with the Press"—because the Press of every country is a very powerful lever, and most men desire to be what is called "popular" with the Press—I say if that is their object I have no fault to find with it. I rather congratulate them upon their courage, and for backing their courage by such an enormous sum to obtain that popularity; but I want to show you that I do not expect that that Press arrangement will do us any serious amount of harm. Mr. Bennett is a very shrewd and far-seeing man. Mr. Bennett was fortunate in making an arrangement with the French Cable Company whereby his Press messages were conveyed at the rate of 4½d. per word. That agreement is about to expire, and I was told only two nights ago by an American gentleman connected with the Press that Mr. Mackay proposed to renew such an agreement with the *New York Herald*, and with any other newspapers who choose to make a contract on similar terms; and, further, that he was prepared to reduce the rate to 3d. for what are called deferred Press messages, and double the rates for ordinary Press messages. The rates of our Company are 6d. for deferred, and 1s. for ordinary Press messages. I have no doubt at all that Mr. Bennett's and Mr. Mackay's cables will get a very large share of Press traffic owing to these reduced prices. Let them, we shall not compete for it, we have no desire to do so; in fact, it would be rather a relief to us. I do not think we should mind if they should abstract it all, as it would enable us to take more of the fully paid messages, and after all it is the fully paid commercial messages that make Atlantic cables pay. But then I naturally ask myself whether, if I were a newspaper proprietor in New York, I should be quite prepared to allow open messages to pass over wires so entirely under the control of two private individuals, and ostensibly started in the interests of one particular paper. I suspect that a very large amount of their carrying power, at all events for the Press, will be for the benefit of Mr. Bennett and not for the general Press of America. That might suit Mr. Bennett very well, but the question is whether it will suit Mr. Mackay's pocket. But probably Mr. Mackay also has an interest which he wants to serve. We are told that Mr. Mackay has become president of a new land line system in the United States which is under his control, and that these cables are laid down to connect with that system. No doubt Mr. Mackay is depending upon that system for his cable messages, but as about 60 per cent. of the traffic between Europe and America is to and from New York, and as that particular traffic is Stock Exchange or produce business, the transmission of those messages in the shortest space of time, as I have previously stated, is of paramount importance to the sender, and having our own independent office in New York, and being also in possession of the business, I can only say that we shall endeavour to keep the position we have gained and deal with the traffic in such a manner as would make it impossible for any outsider to get even a numerical or cable-for-cable proportion of the traffic. As to the remaining 40 per cent. which is obtainable from Chicago, Philadelphia, San Fransisco, and the other parts of America, I think the Western Union are perfectly able to take charge of that. Probably there is no telegraph system in the world covering such a vast area and having a larger number of offices or better managed than the Western Union Company, not only as regards the United States, but also Canada; and I should be very much surprised if a company like the Western Union, which has taken something like thirty to forty years to build up, and which is now perhaps the most successful telegraph company in the world, is likely to be put aside by a company which one might say was only formed yesterday, if it is completely formed to-day. I think I have given you reasons to show that our property is not likely to be injured, that we are likely to keep the position we now occupy, and that the competition we are now going to meet is one which we may consider will relieve rather than injure us—that is, if the opposition carry out the policy indicated in Mr. Mackay's letter. Looking to the transfers (this is immediately for your own interests) which have passed through our office—they are not above the average—and to the decline which has taken place in the value of our shares and that of the Anglo-American Company, I strongly suspect that certain people, who on the Stock Exchange are called "bears," have had something to do with it, and as those shares have all to be bought back again before the transaction is closed, I should be much surprised if I do not see a very considerable reaction in the value of Atlantic cable property. But I have nothing to do with bulls or bears. I only caution our shareholders not to be alarmed. Stick to your property; I believe it is in as good a position as it has ever been in. No doubt if we had less capital in Atlantic telegraphy there would be a larger dividend, but we are in a position to meet the public requirements so completely that I think we shall keep it, and if we do, I expect there will be no falling off in the dividend of the Direct Company. While I admire the pluck and enterprise of Mr. Mackay and Mr. Bennett, I cannot but feel that if they had the experience and knowledge of Submarine Telegraphy that some of us have, they would not have ventured upon a transaction in its nature so risky and likely to be so unremunerative; but when men have more money than they know what to do with, it is not to be wondered at where their desire for popularity is so great that they should spend it in the way they think best likely to attain that object. There is another paragraph in this letter to refer to, and then I am done with Mr. Mackay. That is a paragraph as to which I think the shareholders should know our views. So far as it is the policy of the Board of the Direct Company—I do not speak for the other American Cable Companies—but I think I may venture to say that the opinion I am going to express now will be in perfect harmony with the directors of the Anglo-American Company. As to the remark made in Mr. Mackay's letter about there being no intention on his part to make any agreement with the existing companies, I think I may say that we are in perfect harmony on that point, and so satisfied are the directors of these companies that Atlantic telegraphy has, at all events for a time, been overdone, that they would not now make an arrangement with any additional cables. They do that in the broad belief that such cables are unnecessary; that the money might be much better employed in another direction; and in the further belief that such new capital, if left to itself, will find its own level, and I think there can be very little hesitation in saying that this level will not be a high one. I will now conclude my remarks with what I conceive will be a statement satisfactory to the shareholders. We have £100,000 in debentures falling due in October next. It is the present intention of the directors to pay off that £100,000 at maturity, and we shall take that from the reserve fund. We shall save £6,000 a year by paying off the debentures, and we shall still have a reserve fund equal in proportion to any other cable company. With the power we shall still retain of increasing that reserve fund, a power which a single cable company ought always to hold, I think we shall carry out this transaction with the entire approval of the shareholders. I beg now to move the resolution which I have read, but before putting it to the meeting I desire to say that I am quite willing to answer any question which may be put to me.

Mr. JACKSON said, as to paying off the £100,000, he thought it was a very desirable and wise proceeding. He would like to know to what was attributable the falling off in the traffic during the last six months, and whether it could not be developed by offering advantages which would stimulate it. The cable of Mr. Bennett and Mr. Mackay had been adverted to by the Chairman. They should recognise that trade was free all over the world, and that people were entitled to invest their money as they pleased. No sooner was a large amount of capital subscribed for a cable than the stock fell by about 50 per cent.; but in spite of that fact they found efforts made to put down new cables, and notwithstanding the statements of the directors that the traffic was not sufficient to give half the amount of work which the existing cables could do, something like a fifth of the whole of the cables, that was to say two out of ten, were now to be put down with the uncertain results mentioned, and he thought that, seeing that their traffic had not increased, but had rather diminished, they must look for a fifth less than what they had been receiving. Under these circumstances, he only wished to say that, as far as he was able to look at the question, he hoped the directors would nail their colours to the mast, and if it were necessary to pay a dividend of only 4 per cent. they would have the courage to do it, in order to strengthen the reserve fund. The renewal fund was to be reduced by £100,000 for the reasons stated by the Chairman, and therefore it became most essential to consider what he (Mr. Jackson) had said, as their cable was ten years old. He felt very much gratified to find that something like £10,000 more had been put to the renewal fund than last year.

Mr. JOHN NEWTON wished to give expression to his satisfaction at the remarks which had been made by the Chairman, as it was only a few minutes ago that he heard some other observations in another room at the meeting of the Anglo-American Company. He wished that what the Chairman had said had been said to that much larger audience. He thought that the threatened competition should be fought on business lines. He was one of the ewe lambs referred to in Mr. Mackay's letter, and he wanted and must have his income from his investments. But speaking as one of that class the directors were welcome to the whole of his income from the Company in order to fight the battle till they had punished the competitors who came to interefere with them in the not large return which they derived from their investment. He was glad to hear the Chairman state the manner in which the new competition would be dealt with. As to the position of the Company's property, the Chairman had referred to a certain class of beings who prevailed in Capel-court, who, no doubt, produced some unpleasant feelings among some of the shareholders, although not with respect to himself. He had made a calculation and had found out that the reserve fund of the Company was not £350,000, but £360,000, according to the market value. Writing off £100,000—for the very satisfactory purpose mentioned by the Chairman—which would make the position of the shareholders one of a safe 5 per cent., they would still have something like £260,000 left, which was about £4 5s. per share, and that reduced the price of the shares according to the present market quotation to about £6 each. In other words the total value of the Company's cables, business stations, &c., was under £350,000. From a financial point of view the Company was in a very strong position to fight any competition that

Digitized by Google

might come. There was one observation which he desired to make as to the denomination of the shares. They were £20 shares, and there were no other shares in telegraph companies of that denomination, and if the directors would only make the shares into £10, the shareholders would be able then to compare them, without much trouble, with the shares of the Eastern and Eastern Extension Companies. It would then be seen what a very valuable property the shareholders of the Direct Company had. Supposing their shares were £10, they would represent, according to the market price, bearing in mind their reserve fund, £3 each, as compared with the shares of the other companies, who only paid 5 per cent., and whose shares stood so very much higher. He thought this matter should have their attention. He commended the directors for their pluck in view of the competition, and said that the Company had the finest cable which was laid in the Atlantic. He had, he said, the authority of the maker to say this. Mr. Loeffler himself had told him that there was not a finer cable than the Direct. The shareholders might feel assured that they had a splendid property, and they could keep their reserve fund earning them money without the necessity of investing it by making a duplicate cable. As to Press messages, he thought that the Press information published in the newspapers as coming from America was contemptibly small, as compared with what came from Austria, Hungary, and other places.

Mr. GUESDON said he thought the competition which was about to arise should be dealt with on the broad principle that in the present day they lived under Free Trade. He did not think they had a right to analyse the motives which had actuated the promoters, Mr. Bennett and Mr. Mackay as to their undertaking. It was perfectly certain that the capital of the existing companies was very much more than that for which the lines could be replaced. It was fortunate for the shareholders that the position of the Direct Company was very strong. He could hardly endorse the bright view which had been drawn by the Chairman, as it appeared to him that the more cables there were the more the existing cables would be interfered with, but the extent to which that might go was a question which remained to be seen. He would be sorry to see the cables of Mr. Bennett and Mr. Mackay received in a spirit of antagonism. He would prefer to see some amicable settlement made by which a uniform price could prevail ("No, no.") It must be war to the knife or an arrangement as to the messages which would be advantageous to all parties. He thought the question for the consideration of the directors was, to what extent could economies be practised in the companies? There were now four receiving offices, each company having its own receiving office; and he would like to know what was the necessity of this state of things. There was the item of rent in connection with this matter, under which heading a good deal of expenditure would be saved, and a very moderate increase in the staff would take all the messages that had to be carried. Notwithstanding what the Chairman had said, he expected that the effect of the new cables would be that the tariff would be reduced. He did not expect to see the 2s. tariff maintained, and they had to consider what the effect would be on the aggregate revenue of the year. The Direct Company was in a very strong position, but it could not fail to have a diminished dividend, and therefore he would suggest to the Board to see in what way expenses could be reduced. The companies were overweighted with directors. This Company had eight, and if the number of the directors of the London and Westminster Bank were in proportion to the number here, he did not know what the number of the Board of the bank would be. At present they had only fifteen directors. He did not wish to detract from the talent of the gentlemen at the Board; all that he maintained was, that there was too much of it. He therefore intended to move a resolution on the subject.

The CHAIRMAN: Would you move that as an amendment to the report?

Mr. GUESDON replied in the affirmative.

The CHAIRMAN: I think that you must give notice now, and bring this forward at the next meeting.

Mr. GUESDON intimated that he had not the least desire to do anything that was out of order.

Mr. UNDERDOWN stated that notice of this proposal must be given for the next general meeting.

Mr. GUESDON said that he would do so.

The CHAIRMAN: As to such a resolution as you propose, I have always understood that intimation ought to be given beforehand that it would be brought forward—eight days before the meeting; and that not having been done, what I suggest now is that you should give notice of this proposal of yours for the next half-yearly meeting. It cannot be proposed as an amendment.

Mr. WILLIAM ABBOTT thought the directors might judge, from the tone of the meeting, that they were likely to be supported in the policy put forward by the Chairman. One gentleman had thrown out a hint that an amicable arrangement should be made with the new competitor, but having been connected with all the Atlantic Cable Companies, he (the speaker) might safely say that it was these amicable arrangements that had brought competition on them. So long as contractors and promoters thought that they were feared, and that some arrangement would be made with any cable they put down, so long competition cables would be made. But if the directors were determined, and put their foot down, and said they would make no more amicable arrangements, but depend on their prestige and the exceedingly efficient way in which the service was conducted for a continuation of the support of their customers, they would find that the laying of competing cables would soon cease. He must say that he was surprised that the Press of England had been so wanting in enterprise in making use of the facilities which were given them by the Atlantic Companies for the transmission of messages. As to Messrs. Mackay and Bennett going into an enterprise of this kind for philanthropy, that was their business.

The CHAIRMAN: May I ask Mr. Jackson and Mr. Newton to allow me to deal with the last gentlemen first—Mr. Guesdon and Mr. Abbott. First, with regard to Mr. Guesdon. He proposes an amalgamation of the existing companies. I may say that there was a time, and I did not hesitate to say it at the time, when I thought it would be wise for the Americans to have a submarine cable company of their own. The French people had no cable nor the German people either, and they were desirous of having something to do with the telegraphic communication between their countries and America; and looking at the enormous growth of these communications I was not indisposed that they should be represented. I also said it was perfectly natural that Americans, having attained the commercial position which they had reached, had a perfect right to have their own cable; but the time has now come when I think that each nation has got its proper proportion of representation, and I think we are perfectly right to defend our position. I did not say a word antagonistic or reflecting in any way on the honour or credit of the two gentlemen who are about to bring forward this new cable. On the contrary, I have said that they are men of great wealth, great energy, and great enterprise; but I say that they were going into this business on false grounds. I say I think the expenditure is perfectly useless, and I say more, it is vanity that is at the bottom of it. As to the other remarks which have been made, I would say that there is a great amount of human nature in those who are using the telegraph as in other men. If we were to put all these companies together at the present time I think it would be impossible to have our stocks amalgamated. There is another point—customers like several offices, and if they wish to leave one office they have another to go to, otherwise there might still be more cables laid. I say, therefore, it is the interest of the public and the shareholders that we should be kept distinct. I shall never be a party to amalgamating the four companies, as I think the work is better done for the public, and that the interests of the shareholders are better cared for by the existing arrangement. In telegraphy, emulation is just as applicable as in any other enterprise. Mr. Jackson says that the directors must have courage to do a certain thing. He wants to know what is the cause of the depression in the traffic. I have very often said in this room that there is no greater barometer of trade than the telegraph system. I think there are those in this room who know that ruin has overtaken many, I may say thousands, in America, and the depression is such that it is no wonder that there has been a falling off in our traffic. Men who two years ago were millionaires have now barely sufficient to keep body and soul together. When there is great commercial activity there is plenty of money for telegraphy, but where men have not enough to exist on you may be sure there is no money spent in telegraphy. You will see there will be an elasticity of trade presently. We have seen this state of things before in America, and you may depend on it that we shall have a revival, and after a few months, or perhaps a little longer, having regard to the extent of the country, you will find a return of prosperity, and that telegraphy will partake of that prosperity. Those coming in now will find it a very uphill business compared with what it was a few years ago. They will get a share of the traffic, but I think it will be a small share, and I think, looking at the accounts before you, that we can afford them a small share, and continue to show you good accounts notwithstanding. Do not get frightened. I would say to Mr. Jackson, the directors have courage; let the shareholders take heart and back the directors. We are prepared to fight this battle, and I believe that we shall be able to show you very satisfactory results.

Mr. NEWTON reminded the Chairman of his suggestion as to the division of the £20 shares into £10.

The CHAIRMAN: That is a matter of detail. I confess I do think it would be better if all telegraph companies were on the same level. We shall consider this suggestion, and if there is no great expense I see no objection to it. We were bound, for some reason or another, on the reconstruction of this Company to continue the present arrangement.

Mr. FORD: We followed the lines of the old Articles of Association. There were special reasons for doing so at the time.

The CHAIRMAN: Still, I think Mr. Newton's suggestion is one worthy of consideration, and we should consider it. Probably there may be some good reason against acting on it. But, speaking as I do now, I say I see no great objection to acting on his suggestion, except that it may involve expense. I think that as to the reserve fund I have satisfied Mr. Newton in my remarks already. As to the quality of the cable I think it would be very bad if we cried stinking fish. I think our cable has proved a very excellent one, and in regard to cables generally, when we speak about their age, I may say that we took up a cable belonging to the Eastern Company in the Red Sea the other day (and that, perhaps, is the most trying sea for any cable), and the report of the captain was, "Cable most splendid order." That cable was at the bottom of the sea ten years. I begin, therefore, now to feel that good cables have a much longer life than, perhaps, we have any idea of. In the Eastern Company we have much more frequent opportunities of testing the cables laid down, as they are very often in shallow water, and breaks occur more frequently. As far as we can see, I do not think we are going to throw over our cables because they are ten or even twenty years old. I think I have now answered pretty well everything. I am reminded of one point as to the number of directors, and as to that I have very strong opinions. When your business is well conducted, I say be satisfied. I have sat at many Boards, but I do not believe I have ever sat at any Board where the directors gave more individual attention to the work to be done than the Board of the Direct Company do. I may also say, as far as I am personally concerned, that I am in communication with the Traffic Manager, not merely every day, but many times every day. The interests of the proprietors are, therefore, most carefully looked after, and you may go a very long way to get as good a Board as you now have got. As to the reductions referred to by Mr. Guesdon, I think, as I have said before, that they would not be to your advantage, and a union or any combination of the companies would not be acceptable to the general body, and I am sure it would not be for the interests of the shareholders.

A SHAREHOLDER inquired what precaution was taken as to the supervision of the securities forming the reserve fund. There had been so many frauds lately that he had been induced to ask this question. Only a few days ago, he believed, the shareholders of the London Chartered Bank of Australia were told that their securities were examined every week, and the auditors repeated the same statement, but in spite of that they had now been informed that they had sustained a loss of £120,000.

The CHAIRMAN: Mr. Griffiths, our auditor, will answer that question.

Mr. GRIFFITHS: I am one of the auditors of the Company. I and my colleague attended at the National Safe Deposit Company's offices a few days ago and saw every security, and, in addition, we have had certificates from all the railway companies that we hold the amount of stock represented.

The SHAREHOLDER wished it to be understood that he had cast no reflection on the auditors.

The CHAIRMAN: We have had this question of the securities before us, and I confess we have thought out every possible way of making ourselves more secure. I do not think we could do so unless you could get a man to sit on the securities. You must have trust somewhere. All our securities are in a box in the vaults of the National Safe Deposit Company—the certificates, that is the value. There are three keys to that; two of the Directors hold a key and the Secretary holds a key, so that the box cannot be opened unless there are three parties present. Then the seal of the Company must be forged, of course, before any transfer could be made. There is another guarantee besides that. We, without any fixed dates, examine the securities. I may say to the Board on any day, "You two Directors shall go with me and we will see how the certificates look." Those who have the keys hand them over to those who have not, and that occurs from time to time. If we had a system that was carried out from day to day, I mean at certain times, you would never know what went on between those times, therefore the uncertainty in connection with our system makes it almost impossible for those securities to be touched.

Mr. NEWTON inquired whether the securities were in joint names.

The CHAIRMAN: No. They are in the Company's name, in its corporate character. I therefore say it is impossible to make our securities more safe than they are.

He then put the motion in the usual way, and declared it carried unanimously.

Mr. NEWTON expressed great pleasure in proposing a vote of thanks to the Directors, and said he would take that opportunity to say with regard to dividing the stock that there could be no difficulty in the Articles of Association.

Mr. JACKSON seconded the motion.

The CHAIRMAN said: Gentlemen, on behalf of my colleagues and myself I can only tell you that we are deeply interested in the success of the Direct Cable Company, and we shall try as far as we can to maintain our present dividend.

The meeting then closed.

---

## ANGLO-AMERICAN TELEGRAPH COMPANY, (LIMITED).

The half-yearly general meeting of this Company was held on Friday, the 8th inst., at the Cannon-street Hotel, the Marquis of Tweeddale in the chair.

The SECRETARY read the notice convening the meeting, and the report of the directors was taken as read.

The CHAIRMAN said: Gentlemen, before asking you to adopt the report, I shall, as usual on such occasions, offer a very few observations upon its contents. You will have noticed that the revenue, including the balance brought over from last half year, amounts £259,814, and that the traffic receipts are rather less than they were during the corresponding period of last year by the amount of £10,089. This is, no doubt, due to the depression which has prevailed in commercial and industrial circles, and which, I regret to say, is still the case. However, we must trust to an improvement in the future. The expenses amount to £61,658, which is slightly in excess of last year, due in the main to a sum which was paid to Mr. Harding and to one or two other small items. Under Abstracts A and B in both cases there is a slight decrease; in Abstract A you will observe there is a decrease of £426, and in Abstract B there is a decrease of £177. Then, gentlemen, the accounts show that we are paying on the ordinary stock 20s. per cent., making for the whole year 3¼ per cent. The report informs you that the ship which is employed in repairing the cables has been thoroughly overhauled, at an expense which was absolutely necessary. The ship now is in perfect condition, and capable of undertaking the repairs of cables in the sea at whatever depth may be necessary. Then, gentlemen, there is a paragraph which gives you all the information which the directors possess with regard to the two new cables which are about to be laid in the Atlantic. Considering the number of cables in existence—as you are aware eight in number—and the fact that, owing to the duplex system, they are practically doubled or something like it, and the traffic if anything is certainly stationary, if not slightly falling off, you will understand that your directors received with some surprise the intimation that two more cables were going to be laid, and they were still more surprised that gentlemen should be found to invest money—something over £1,000,000—in an enterprise for which, as far as we can see, there is no necessity whatever. The traffic, as I say, is rather less if anything than it has been for the last year or two, and the work never has been done in the history of these telegraph enterprises with more efficiency, greater speed, greater accuracy, and greater secresy; therefore it is impossible to conjecture what reasons there are for these two new cables being laid. You are aware that we possess no monopoly of the Atlantic, and that it is open to any person to lay a cable between Europe and Great Britain and America, both North and South. I am afraid all we can hope to do is to look on and do our best to meet this additional competition with which we are threatened. Gentlemen, you will remember that on the last occasion a discussion arose on the subject of the renewal fund. Of course you have noticed that £75,000 has been placed as usual to the renewal fund. I dare say you will remember that on the last occasion a discussion arose as to whether the time had not come when, in the opinion of your directors, it might be advisable to reduce the sum of £150,000 per annum placed to the renewal fund to a lesser figure. I believe the suggestion was made by one or two hon. proprietors that it should be reduced from £150,000 to £100,000 a year. I think at that time I said that your directors had given very careful consideration to this question, and that having in view the number of cables belonging to your Company, and the condition of one or more of them, it was not in the interests of the shareholders and of the Company that any alteration should be made. Now, gentlemen, this question has been again carefully considered by your Board, and I have to announce to you that they have come to the same decision to which they came on the previous occasion, namely, that after a very careful examination of the question, and after having consulted those persons whose opinions are most worth having—and I may mention that you have on your Board persons who are experts, I may say on this question and on the probable existence of cables, their present condition, and other matters affecting their existence—and they agree in the wisdom of the course we pursue. Now, gentlemen, I need not tell you that your Board have no interest whatever in favouring any class of shareholder; their only object is to do what is right in the interest of the Company, and they have, after consulting those most competent to give an opinion on this subject, come to this unanimous decision, that the time has not arrived when it would be in the interest of the Company to make any alteration. It is quite clear, gentlemen, that it is one of the most important, if not the most important, duty of your directors, to decide what sum should be set apart every year for the maintenance of your property in a thoroughly sound and efficient condition, and I venture to think in a Company like this it is, perhaps, the most important duty which they have to perform. It is one of great responsibility, because they have no wish to deprive shareholders of any class of an increase which might properly be made to the dividend. Gentlemen, I think after what I have said that the most captious gentleman here present will admit that the policy I have indicated is under the circumstances the wisest and most prudent that can be pursued. Gentlemen, there is another argument which I think is well worth considering, and it is this: that we are on the eve of a very severe and serious competition, and that in view of this it would be very impolitic to reduce the annual sum placed to the renewal fund, which, if this competition were very serious, we might find it difficult to maintain. Gentlemen, for these and other reasons which I need not enter into now, I trust that you will agree with your Board in the policy I have indicated. I do not think it is necessary for me to make any other remarks, and I shall therefore conclude with moving the adoption of the report in the usual language—namely, "That the report of the directors and accompanying statement of accounts to the 31st December, 1883, submitted to this meeting be, and the same are hereby received and adopted, and that the following dividends, all free of income tax, be now declared—that is to say, balance dividend of 20s. on the ordinary consolidated stock for the year ending 31st December, 1883, making, with the previous payments, 3¼ per cent. on that stock for the year 1883; a balance dividend of £1 10s. on the preferred stock for the year ending the 31st December, 1883, making 6 per cent. on that stock, and a first and final dividend of 10s. per cent. on the deferred stock for the year ending 31st December, 1883."

Sir DANIEL GOOCH, Bart., M.P., seconded the motion.

Mr. THOMAS SMITH said that he was very pleased with that part of their report which informed them that their cables were in good working order. They had had a good deal of special pleading by the chairman for the enormous reserve fund. He went away from the last meeting thinking that they would never again see more than £100,000 added to the reserve fund, and he had given notice that he should move an amendment at this meeting that only £25,000 should be added this half year, making £100,000 for the year, which would bring up the amount to something like £505,920, and which, with additions and interest at the next annual meeting, would bring the reserve fund up to £620,000. He contended that it was a monstrous shame that the shareholders should be asked to set aside 50 per cent. of their earnings. The directors had told them from time to time that they had such concessions from the Americans, from the Western Union, from the French, and from our own postal authorities, that they did not fear competition; and yet they now said that they were afraid to divide the fair earnings of the Company. He contended that they were playing into the hands of their opponents, and that the credit of the Company had suffered very much by the policy pursued by the Board. The price of their shares on the Stock Exchange that day was the very lowest of any trash in the Telegraph Market. [Cries of "No, no."] There were many people in the country whom he had induced to buy preference stock, thinking it was perfectly safe, who had been frightened into selling it. He moved as an amendment, "That the sum carried to renewal fund be £100,000 a-year in future, and that the sum to be set apart to renewal fund now be £25,000, in addition to the £75,000 already applied to it."

Mr. ASTON seconded the amendment, thinking the Company would be in a stronger position if it were carried.

Mr. BAKER said that if the Mackay and Bennett parties could lay two cables 6,000 miles long to America for £800,000, this Company now had more than enough to lay one cable, and for that reason he quite endorsed

Digitized by Google

the remarks that they should go back to the amount they appropriated to the renewal fund in 1877, which was £100,000 a year. Taking a series of years the shareholders had received a beggarly pittance of 4 per cent., the public had received all the plums, while the shareholders had pulled the chestnuts out of the fire. He thought it was about time that they should have a little for themselves. They had been holding on and holding on, and the result was that their stock was at 60 per cent. discount. He thought they should take some powers by which they could redeem their absurd capital. They had £7,000,000 of capital, £2,000,000 of which was watered; they should wipe that out by taking £50,000 out of the reserve fund, and redeeming the deferred stock, and then in two or three years time their ordinary stock would stand at 55 or 60.

Mr. JACKSON said that when the two new cables were laid they would have their income reduced something like one-fifth [cries of "No, no."]. They might look for a reduction in the ordinary course, and if the new company got its share of the traffic it would be a fifth of the receipts, and under those circumstances if they had no renewal fund, and had to raise preference capital, where would they be? He contended that on this subject the directors knew more than the shareholders.[cries of "No, no."]. At the same time he thought that they might put it to the directors whether, having such an enormous reserve fund, they could not slightly increase the dividend. There was one thing to which he would like to call the attention of the directors, and that was the enormous charge for the transmission of addresses, and he thought that that subject might be considered by the Board in view of the coming competition.

Mr GRIFFITHS said that it seemed evident that they must have competition in the future, and therefore the shareholders should consider the position in which they were placed. Their dividends had fallen year after year, and there were only two ways in which they could ever increase them—one was by reducing the expenditure, and the other by increasing the business. He thought that they should try to reduce their heavy expenses rather than put the enormous sum of £150,000 a year to a comparatively unremunerative investment. They were told that there were eight cables in the Atlantic, and that they were competent to transmit all the messages, so that why should they be asked to provide money for another cable? This was all the more unnecessary, as by the duplex system one cable could do such a large amount of additional work. They were told by their chairman that their business was likely to fall off, and if their cables were more than sufficient at the present moment to transmit all the business, surely they would be much more than sufficient if the business fell off. If in addition to that two new cables were laid, there would not be nearly sufficient business for all the cables that were in the Atlantic. On these grounds he urged on the Board a reconsideration of their policy.

Mr. BLACKWELL thought that a great many of the remarks that had been made about reducing the sum laid aside told in exactly the opposite way to what the speakers intended. He thought that they should at once reduce the tariff to a shilling, so as to meet the demands of the public, and get all the business there was to be had. It was desirable to have as strong a reserve fund as possible, in order to be able to compete with the new cables when laid. Last time they carried over £13,263, while this time they only carried over £657.

Sir JOHN SWINBURNE asked what would be the cost of a new cable—whether it would be £600,000, £800,000, or £1,000,000?

Mr. WEAVER: Where to?

Sir JOHN SWINBURNE: The United States. (Laughter.)

Mr. WEAVER: Our cables do not go to the United States direct, only to Newfoundland. We can only tell you what they have cost.

Sir JOHN SWINBURNE thought that if a new cable could be laid for £800,000 their reserve fund ought to be reduced. If they were to earn only 3¼ per cent. they had better wind the Company up. They were spending for working expenses £77,000 a year, or £80,000 including the directors' fees, and he thought that some steps should be taken to reduce that enormous outlay.

A SHAREHOLDER thought that the new cables ought not to be absorbed into this Company without the consent of the shareholders.

The CHAIRMAN: We cannot do it by the Articles of Association.

Mr. TWEED said that he came to this meeting expecting to receive much more information with regard to what were the ideas of the Board in respect to the new competition. He thought they should be told when the appropriations to the renewal fund would cease. He asked whether the new company was started on fair and honourable grounds, and was likely to compete very seriously with them? He asked also whether any sinister motives influenced those who started the new concern? He would like to know if it had been done for the purpose of knocking down the shares of this Company, and perhaps the Board would say whether they believed, when the new cables were sunk, that it was likely materially to injure the trade of this Company, and in what respect—whether the new comers had the influence and the power by which they could get the business away from this Company?

Mr. NEWTON thought it would elucidate their position with regard to the reserve fund if the meeting had definite information as to what would be the cost, as near as possible, for a cable to be laid from Valentia to Newfoundland. He hoped their reserve fund would remain intact until the shareholders in general meeting sanctioned the laying down of another cable. He hoped that the new concern would not be bought up by this Company, but that they would show themselves capable of defending their own. The reason there were so many cables in the Atlantic was—he did not say it offensively—that the directors had "squared" their opponents. The shareholders were sacrificed, and the promoters of new companies obtained very honourable positions, with very satisfactory salaries attached to them. No less than £33,000 a year was distributed in the way of salaries to telegraph directors, and it was those who were out of the charmed circle, and who wanted to get in it, who promoted new lines with the view of their being taken over.

A SHAREHOLDER said that the entire capital of the Company was valued in the market at something like £2,500,000, and deducting from that the £550,000 in cash, consols, &c., the market value of the Company was now assessed at under £2,000,000. That to him was a confusing state of affairs, and he could not conceive why the price should be so low. He asked whether the cables were sound and in good order, or if they were weak?

The CHAIRMAN: I shall endeavour to the best of my ability to answer the numerous questions which have been addressed to the chair. Most of them refer to one subject, but should I omit to notice any questions that have been addressed to me, perhaps honourable proprietors will remind me of it, and I will endeavour to rectify the omission. With regard to the gentleman who has last spoken, I may say that the cables are in sound and in good working order; but you must remember that their ages are very different, and that, therefore, some allowance must be made for depreciation, which, of course, it is not my duty here to estimate. The oldest cable is fifteen years old.

A SHAREHOLDER: Pardon my interrupting you, the present market value is only four years' purchase of your gross receipts.

The CHAIRMAN: Gentlemen, I really have nothing to do with the price in the market. The second cable is eleven years old, the third is ten years, and the last four. There must be some difference in the condition of cables which have been so much shorter time under the ocean. Mr. Newton asked me the price of a cable, and the same question was addressed to me by Sir John Swinburne. The price would of course depend on many things. A cable for cash would be bought naturally much cheaper than one on credit. Then a considerable difference would depend on where the cable gave up. For instance, the French. If that were to give up it would cost probably between £800,000 and £900,000, whereas, between Valentia and Newfoundland it would cost very much less, probably something like £600,000. I do not wish to be fixed in these figures, but I believe in round numbers those are tolerably accurate. One gentleman (Mr. Tweed) complained that I did not give information about the prospects and intentions of the new rival cables. Well, gentlemen, I must confess that I do not know anything about their intentions, or their prospects. With regard to the share of traffic that they are likely to take, that depends a good deal on the efficiency with which our cables are worked. I suppose it would be recognised that eight cables would do the work together more efficiently than two cables worked together; therefore, the probabilities are the two cables would not take their full share of the traffic. That is the only opinion I can form on the subject, simply because traffic between two countries, especially between London and New York, must be more effectively and more efficiently carried through by a system which embraces eight cables rather than by a system which embraces only two. With regard to the tariff I know nothing of their intentions, and am therefore unable to give any information. Messrs. Bennett and Mackay are not gentlemen to signify their intentions to us or to anybody else. Then with regard to the expenses. On previous occasions I have announced to you that the Board have the question of the expenses constantly before them, and I think I am accurate in stating that for the last two years reductions have been gradually made. All I can say with regard to that point is that your directors will continue to give their attention to that most important subject. I do not think there is any company of this sort which is worked more economically than this Company. I think a gentleman inquired whether we have power to buy our stocks. I think I am right in saying that we have no power to purchase our own stocks.

A SHAREHOLDER: Can you get powers?

Mr. BURT (the solicitor): Yes, by an Act of Parliament.

The CHAIRMAN: With regard to the important point, namely, the amendment which has been moved, that the sum to be set apart to renewal fund should be £25,000 instead of £75,000, I do not know that I have much to add to what I have already said. I have stated to you that the Board on two separate occasions, shortly before this meeting, and shortly before the meeting that was held six months ago, considered this matter with the utmost care and deliberation, and they were advised, as I have already told you, by those most competent to form an opinion as to what sum should be set apart to maintain your property in an efficient state. Now, that is the duty of directors; they are bound to maintain the property in a proper condition, and they have in view the prospects before them of competition, and various other points to which I need not refer. Well, gentlemen, we have come to the conclusion that it is not desirable that at present we should reduce that figure. One gentleman made the same remark last time, I think, that has been made this time, and I am prepared to give very much the same answer. He said: "Can you fix, or will you fix, some particular figure, beyond which you will not go—some figure which you think is that at which, if arrived at, would render it unnecessary to lay by so large a sum?" The answer I gave then I give now: "The time has not come for the discussion of that question." I said, as far as I was personally concerned, and the Board also, we should not be disposed to say that we must reach £1,250,000, but I was not disposed to lay down any hard-and-fast line with regard to the figure that is necessary. I must remind you the oldest cable we have is the Brest cable. That would take between £800,000 and £900,000 to replace. Take the case of our neighbours—take the case of the Direct cable. There is a company with one cable; they have already £340,000 to the credit of their renewal fund. It is quite true that they have only one cable, and that, perhaps, demands a larger proportion; but you must bear in mind that if you are to retain your share of the whole traffic you must keep up the number of cables stipulated by the Joint Purse Agreements.

Mr. SMITH: What time would be required to renew a cable?

The CHAIRMAN: It would take a year.

Mr. SMITH: But your traffic still goes on.

The CHAIRMAN: I really trust that hon. proprietors will support

Digitized by Google

the Board in their policy. Generally speaking I think that Boards are rather too much disposed to meet the shareholders with regard to dividends. It would be much more pleasing to me to be able to advocate a larger dividend on this occasion instead of seeing a number of gentlemen before me who are rather dissatisfied, if they have not angry looks. If we gave a larger dividend, probably I should find them highly satisfied, and go away with a very amiable feeling towards the gentleman who presided over this meeting; therefore it must be clear to you from every point of view we have no desire whatever to apply to the renewal fund a larger sum than men of business deem desirable. I trust, gentlemen, with these remarks Mr. Smith will leave the matter in the hands of the Board with the full conviction that they will, at the earliest opportunity, take pains to consult his wishes and the wishes of those gentlemen who have supported him on this occasion.

Mr. NEWTON asked whether the reserve was available for the equalisation of dividend?

The CHAIRMAN replied that it was not, and said that it was strictly a renewal fund. He wanted to point out the position in which they were placed. Under the Articles of Association the amendment, even if carried, would be of no avail on the present occasion, but if Mr. Smith would withdraw it he might move it in some other form; something to this effect, "That the meeting recommends that for the next year the amount to be set apart to the renewal fund be reduced."

Mr. SMITH said that it was the intention of the amendment that the reduction should apply to the future.

The CHAIRMAN said that at the next meeting, if the shareholders were not satisfied with the policy of the Board, they could then bring the subject up again.

Mr. SMITH thought that after the strong expression of opinion on the part of the shareholders the Board would carry out their wishes.

The motion for the adoption of the report was then put and carried.

Mr. SMITH then moved "That the meeting recommends that for the next half year the amount to be set apart to the renewal fund be reduced."

This was seconded by a shareholder and carried, 46 voting for and 29 against it.

Sir JOHN SWINBURNE moved—"That this meeting, looking to the decrease of traffic and the anticipated competition, requests the Board of Directors to make every effort to reduce the current expenses." He would just point out that the £80,000 a year they were spending to carry on this business did not include any repairs, the cost of which all came out of the renewal fund.

Mr. WEAVER: No, no; certainly not. All ordinary repairs are always charged to revenue. It is only renewals to a large part of the property that are ever charged to the renewal fund. For instance, in the repair of the Brest cable, when we put in 400 miles of new cable, we charged that to the renewal fund because it was a renewal; but all ordinary expenses are charged to revenue, and therefore you are not right in saying all the repairs are charged to the renewal fund.

Mr. GRIFFITHS seconded the motion.

The CHAIRMAN hoped the meeting would leave the matter of the decrease of the expenses in the hands of the Board, who had the subject constantly before them, and he might say there was no company of the kind in which the working expenses were so moderate as in this Company. He would point out that if the tariff were reduced, the tendency would be rather to increase than reduce those expenses, because the more messages they sent the more officers they required, and there was no probability of any important reductions being made; but if a reduction could be made at any future time, they had his assurance, and that of the Board, that it would be made. He trusted that under those circumstances they might part without any resolution, which, in fact, amounted to this, that the Board were not making every effort to reduce the expenses.

Sir JOHN SWINBURNE said that he was entirely in the hands of the meeting, and, after the assurance of the chairman, he would withdraw his motion.

The retiring directors and auditors were then re-elected, and the meeting closed with a vote of thanks to the chairman and directors.

## CUBA SUBMARINE TELEGRAPH COMPANY (LIMITED).

The ordinary general meeting of the shareholders was held at the Company's offices, No. 61, Old Broad-street, on Wednesday, Mr. Joaquin de Mancha, the chairman, presiding.

The SECRETARY (Mr. James Scott) read the notice.

The CHAIRMAN in moving the adoption of the report and accounts said that the accounts were so clearly laid before the shareholders that he thought a very few words on his part would be sufficient before he asked them to pass those resolutions. They would see that their earnings had been nearly £19,000, and after deducting the expenses, besides the repairing of the new cables, there would be £9,194 to divide. That they were going to do in the following manner:—£3,000 would go towards the dividend on the preference shares, and they purposed asking them to confirm the payment of a dividend at the rate of 7 per cent. per annum for the last half year, free of income-tax on the ordinary shares. They had had rather an anxious time during the last six months on account of the breaking of the cable, but they were very fortunate in having an engineer who was most zealous and intelligent. He had carried through the operations most effectively, and in his last report he said that both the cables were working in an admirable manner. Therefore, they thought that the next half year opened with brighter prospects than they had anticipated. The cost they would see up to the 31st December was £4,000, but since then the work had been going on, and had now been completed, and there would be about £2,000 to come to this half year. Mr. Keith had been nearly two months occupied with those repairs, and he had done them, as on former occasions, in a most effective manner, and had taken the greatest possible care to save the money of the Company. He thought, therefore, taking everything into consideration, they must congratulate themselves on the present state of affairs. He thought he had nothing more to say, except that they had not yet been able to get the money from the Spanish Government. The King had given an order that the money should be paid, but unfortunately kings sometimes disposed of what did not exist, and when the directors applied for it they were told that they had not the money to give. The Board hoped, however, that before long they would be in possession of that money. With these few words he would beg to propose "That the report and accounts, now submitted, be received and adopted."

Mr. ALEXANDER F. LOW seconded the motion.

Mr. COCHRANE said he should like to ask an explanation of one or two items which occurred to him. If he were not mistaken there was a considerable advance under the item of salaries in the London office—an advance at the rate of £200 a year. Perhaps it would be satisfactory to the shareholders to have an explanation as to this advance in the salaries. There was also an item of rent, which occurred only once apparently in the twelve months, and not in the half-yearly statement. That was under the second heading of expenses at stations. It did not appear in the last balance-sheet they had, but he supposed it appeared in December, 1882. Then he noticed an advance in an item—he did not know whether it was a delicate point—that was the agents near the Spanish Government. He had some hesitation in asking for information as to that, for the specially important reason that he knew something about Spain and Cuba, and that this was a somewhat difficult matter to deal with. There was an item he did not understand—the dividend in the revenue department amounted to £8,800, but in the capital account it was £8,587 10s.

The CHAIRMAN remarked that the income-tax made the difference.

Mr. COCHRANE went on to say that he thought the shareholders had great reason to be satisfied with the manner in which the business was being conducted, while there were so many concerns going back.

A SHAREHOLDER asked whether there was any chance of a competition which might throw a cloud over the future prospects of the Company?

The CHAIRMAN replied that there was none that he was aware of. In answer to the first question as to the increase of expenditure, he begged to say that as the last half year was a very profitable one, and as there had been a good deal of work in the office, the Board thought it advisable to grant a bonus to the employés in the head office. With regard to the £72 for rent, they formerly used a portion of the offices of the Government in Havanna. They had been since obliged to take offices for themselves. As regarded the dividend, the figures were put in round numbers, but the income-tax would make the difference between the one and the other £62 10s. The income-tax was deducted from the ordinary shares, but the preference shareholders had to pay it. As to competition, there was always competition. There was another line, and if any of the cables of this Company did not act, then they came in. It was rarely used, however, and up to the present they had not suffered any damage from it. On the contrary, they would find in comparing the number of messages this half year with the same period of 1882, that they had an increase of 1,300 messages, and, although that had not brought in so much money as he should like, that was in consequence of the knowledge they had exercised—he meant the gentlemen who used the telegraph cables. They had methods of diminishing the cost, so that one word signified a whole sentence, and instead of the Company getting £1 they would only get 15s. But there was an increase of £800 from 1882 to 1883.

The resolution was then put and carried unanimously.

The CHAIRMAN then proposed that dividends be declared on the ordinary shares, free of income-tax, at the rate of 7 per cent. per annum, and of 10 per cent., subject to income-tax, on the preference shares, payable on and after the following day.

Mr. LOW seconded the resolution, which was agreed to.

A cordial vote of thanks to the chairman and directors and to the engineer and secretary closed the proceedings.

## THE METROPOLITAN BRUSH ELECTRIC LIGHT AND POWER COMPANY (LIMITED).

An extraordinary general meeting of the above-named Company was held at the Cannon-street Hotel, London, on the 12th inst. Mr. John Hamlyn Borrer presided.

The SECRETARY (Mr. Robert Wilson) having read the notice calling the meeting,

The CHAIRMAN said: I suppose you will take the resolutions as having been read.

A SHAREHOLDER inquired how many proxies the committee had, and how many the directors had?

The CHAIRMAN: We have not counted them. Before the resolutions are placed before you, it is my privilege to afford you an explanation of some matters which is imperatively called for in connection with the various circulars with which you have been inundated, the cost of which, with the expenses of the committee, will have materially reduced the funds which they say they are so anxious to preserve. As to legal matters, I understand that we are being represented on all sides as being desirous of protecting the promoters, and as being dragged unwillingly along in the direction of proceedings. True it is that in the face of the opinions

Digitized by Google

quoted at the last meeting we thought we should have been culpable in spending money upon lawsuits.

Admiral Sir E. INGLEFIED (interposing) said that the last meeting was adjourned in order that the committee might make a report. He saw a large quantity of papers that would take up a good deal of the time of the meeting, and —— ("Chair, chair !")

The CHAIRMAN (continuing): I will give you my reasons for wishing to make some statement first, and it will save time. I believe it is my right to claim the privilege from you to make some statement, and I believe it will make your time shorter afterwards, because I shall be able to place things before you which will render it unnecessary for much to be said that otherwise might be said. I shall make good that promise even if you think I am not quite as short as I might be. I undertake to say that the facts I shall place before you will save an immense deal of time afterwards. I was saying that we have been represented as being desirous of shielding the promoters, but that is not the case, for we have, as I was about to say, received further information, and further facts have been produced, which make the case seem stronger, and if you are not unwilling to take the chances of the law, our declared policy should show you that we have no wish to hesitate. The opinion that liquidation is necessary in order to get evidence to fortify the case of course complicates the matter, and it is my plain duty to point out to you that liquidation at once gives the Anglo-American Company the right to refuse us any royalties they have promised on their business in our district. It is possible, however, that they might find it to their interest to continue the arrangement.

A SHAREHOLDER: I rise to order ("Chair, chair").

The CHAIRMAN: I must remind you that outside the report, and not touching any of the statements that have been made there, the numerous circulars issued by the committee contain statements which it is my right to answer. They are outside the report, and many of them were previous to it. The history of the relations between the Board and the committee up to the end of last month had been put before you in various circulars, and there is no occasion to refer to them previous to that time. But on the day on which the committee's report was posted I must inform you that, at Mr. Brown's request, Mr. Tottenham and I met him at Mr. Morris's office. He brought notice of the meeting, resolutions and all, which I had been shown the previous afternoon, but had been refused a copy to take home and consider, and Mr. Brown said he was instructed that unless we then and there agreed to this notice being sent out, without our having an opportunity of carefully considering the resolution, and before we had seen the committee's reports they would take their own course and we might do as we thought best. The wording of some of the resolutions was slightly altered, and thinking every concession that could conduce to peace a duty, we then assented to this most strange demand. We are said to have broken faith with the committee, but there are two sides to that question. No doubt the report is supposed to be toned down by the circular, but to issue a report setting forth in the most decisive manner that as far as this Company is concerned the provisional orders can in no way be carried out advantageously, and then to send out a somewhat milder circular with it expecting us to regard that as acting up to the understanding that the business of the Company was to be carried on, was like stamping on a man's corns with all your might and saying at the same time, "My dear fellow, I would not hurt you for the world," and expecting him to regard you as a tender and sympathetic friend. Our distinct understanding with the committee was that the provisional orders were to be preserved and the business of the Company carried on (interruption). Surely you must wish to understand the position in which both sides come to you. The fifth paragraph of the circular issued with the committee's report is one in face of which they could not assent to the payment of the deposit on the Holborn order, yet they know as well as we do that unless this is done the whole field of the business which they agreed with us should be kept a hold of falls from us absolutely on the 25th of this month, and then, when in face of this and other paragraphs in the report containing a too manifest declaration that they had no intention of preserving for you that part of your property to ensure the safety of which we had made every possible effort (to the very verge of humiliation), or of acting up to the understanding that the business of the Company was to be carried on, we thought it necessary to take independent action in order to save your property from being wrecked and thrown away, the committee turn round and say that we broke faith with them. Here, however disagreeable, I must allude to this very bitter and venomous circular last issued by the committee. There is one statement affecting my postion and that of Mr. Tottenham as directors—not personally—namely, the statement that I had told the committee that I had "pledged myself to protect the original directors." Now, there is only one word which properly describes that statement—and I do not choose to use it. This is what it springs from. On the morning before his resignation Sir Michael Kennedy told me he heard that grave charges were to be made against him in the report, and that if such was the case he should feel obliged to remain on the Board in order to make answer for himself. I therefore asked the committee if it was the case, and was told that no charge was brought against Sir Michael Kennedy, except that of having made a bad bargain in the licenses. Mr. Grenfell similarly placed his resignation in my hands, on the understanding that if the report accused him of anything dishonourable I should not accept it, so that he might have an opportunity of answering for himself. I therefore again asked this question of the committee on his account, and received the same answer. Whatever answer the committee gave it affected simply the resignations of these two gentlemen, and had nothing to do with my action one way or the other. I cannot sufficiently reprobate the tactics which distorted these circumstances into the accusation made by the committee. I defy any one to prove that I have the remotest desire to screen any person connected with the past history of the Company who has acted improperly in any way whatever. There are a great many personal matters which I should like to refer to, and perhaps you will let me do so later on, but I will put them aside in the conviction that you will not believe in them. I am justified in regarding any man with diminished respect who could place them before you. The issue before us is very simple. The committee say, "Fight and don't work." We say to you, "Fight and work too." They say, "Put all your eggs into one basket"—the basket of legal proceedings with a rather uncertain bottom. We say, "Put some of the eggs there by all means, but have something else to fall back upon." The committee intimate pretty plainly that they believe our talk about overtures for taking up some of our districts was all humbug. Now, when the gentlemen with whom we were negotiating in this matter heard that a committee was at work, with Mr. Peebles as its chairman, they made so certain that the Company would be wrecked and made an end of, that they were disposed to throw the whole thing up, and in confirmation of their fears came the astounding declaration that the committee had filed a petition for winding up the Company, coupled with the opinion that we could not profitably work our districts. In face of that they say to us, "Where is your man? why does he not come forward? why does he not bring us a binding offer in writing? then perhaps we will believe you." I do not know how people are to be expected to bid for that which its owners assert to be valueless to themselves. Well, I think that any one who would obstinately get up again after receiving such knock-down blows, and who persists in desiring to deal after such statement that the provisional orders were worthless to this Company, must be a very strong man indeed, and must know particularly well the value of the orders. Well, our man is strong enough to persist in standing up, and obstinate enough to think that he knows the true value of our provisional order, and is here to-day to say that he will back his opinion in a most substantial manner by finding a large amount of the capital to put into the work. We told the committee the name of the firm with whom we were negotiating, and the names of the gentlemen who were interested in it, and the very terms that were being talked of, but they treated all this as rubbish, and the temper with which every piece of information was received by the chairman of the committee was such that if he had asked me whether I had got a coat on my back or not, I should have felt certain that on receiving an answer in the affirmative, he would at once have set to work to prove that it was shoddy. They quote the opinions of several gentlemen to prove that the estimate, the correctness of which I stand by, is a rotten one. But it has been my misfortune not to have met any person of standing in the electrical world who knows the names of these gentlemen as authorities in such matters. The committee have taken the Holborn estimate to bite upon, and have in their own opinion reduced it to pulp. They say that the £14,400 would have to be increased to £17,000, with an addition of £2,000 for working capital; that the machinery spoken of is unknown; that the working expenses of coal, wages, &c., are too low by £586; that granting the 3,000 lights there would be a net loss of £1,144 per annum, and that continuous supply is not arranged for as required by the provisional orders. Mr. Crompton, the weight of whose opinion the gentlemen quoted by the committee will not care to question, reports that, taking Mr. Ward's estimate as it stands, and carrying it out as was proposed, the capital would be fully sufficient; that the coal bill is £100 more than it need be; that the other working expenses are too high, and, in fact, he fully endorses the conclusions arrived at, except that he points out that the income from 3,000 20-candle lamps at the price of gas would be considerably more than Mr. Ward reckoned on; and that the return on the capital would be therefore higher. He does more than this. He says that the amount set down by Mr. Ward for engines and dynamos is ample to provide as much reserve power as would allow of accumulators being altogether dispensed with if desirable; and also that if we set up the installation as a distinct undertaking, instead of arranging it as one that could be afterwards extended (which Mr. Ward was instructed to do when preparing his estimate) the mains could be put down for £700 less. These deductions from capital outlay, together with the larger income which Mr. Crompton thinks would be obtained for 3,000 lights at the price of gas (no deduction being made for the amount allowed for working expenses), give a far better result than we ventured to hold out to you. Mr. Ward was particularly instructed to take care that his estimate was on the safe side, and his assurance that a good margin has been left in all directions has been more than borne out. (Voices: "The report of the committee; put it to the vote.") I have been accused of withholding Mr. Crompton's report from the committee. That report came into my hands on Thursday evening, the day——

A SHAREHOLDER: Let us know something about electric lighting.

The CHAIRMAN: I am answering the accusations made against us in the circular.

A SHAREHOLDER: It is wasting time.

Mr. STEWART: I submit to this meeting——(loud interruption).

The CHAIRMAN: To put this matter briefly, Mr. Crompton is here himself, prepared to support our estimate in every way.

Admiral INGLEFIELD: Gentlemen, the committee were appointed by you; the directors were not appointed by you. We wish to report to you what we have done.

The CHAIRMAN: Allow me to put this point before you very briefly. There is a gentlemen here prepared to find capital for half the work which the committee say cannot be done except at a loss, and Mr. Crompton is here to answer any point.

A SHAREHOLDER: Is any gentleman here ready to give us back our money?

A SHAREHOLDER: Let us hear the committee.

Another SHAREHOLDER: Let us hear something about the prospects of electric lighting.

The CHAIRMAN: That is what I want to tell you. This gentleman wishes to know something about the prospects of the electric light. That is what I wish to tell the meeting. I have given you the authority of the

Digitized by Google

highest name in London in support of our estimate, and further, there is the support of Mr. Callender, who is ready to find half the capital to work it with, and there are some people ready to assist in taking up several of our provisional orders, and if that is not a demonstration that our estimate was a right one to put before you of the Holborn work I do not know what is. It is on that distinct point that we have been more attacked than on any other.

A SHAREHOLDER: Let us hear Mr. Hammond's proposal.

The CHAIRMAN: Mr. Hammond has put a proposal before you, but in the present position of the Company it was impossible to consider it. His proposal has only just come before us. It will receive full consideration, but it is a matter which requires great care, and cannot be decided on in an hour. Please remember in what I am doing that I am doing what I can for myself [laughter]. You know my interest in the concern. I cannot commit, therefore, anything that would be injurious to you without hurting myself still more. My stake, I believe, is double that of any two of you—my interest in the concern. There are many points which I should have wished to refer to, but I will leave them. It must have saved time to show you that we have the highest support for the Holborn estimate, and that people are ready to find the money required. [Voices: "The report, the report."] I will now ask your committee to move the adoption of their report, but I think the bottom has been knocked out of it.

Mr. BROWN wished to make a short personal explanation. The chairman had thought fit to say that he signed the notice without due consideration. He (Mr. Brown) wished to state that the notice was signed in Mr. John Morris's office.

The CHAIRMAN: True; at ten minutes' notice.

Mr. BROWN, continuing, said that Mr. Morris was not the man to sign anything without due consideration. He had the thing before him all the morning, for at least three hours, before the chairman met him (Mr. Brown).

Mr. ALEXANDER PEEBLES (chairman of the committee) then moved the adoption of the report of the committee. He stated that the committee had met daily for forty days, and had on each occasion been engaged for many hours. After a few preliminary observations as to the circumstances under which he joined the committee, he assured the shareholders that it was with great regret that the committee were driven to arrive at the conclusions embodied in the resolutions before them, which had been acquiesced in by Messrs. Morris and Messrs. Linklater. He then dealt with the salient points in the report of the committee, and with regard to paragraph 5 stated that the committee considered that the agreement with Mr. Hammond would be an improvident bargain. He maintained that the net profit referred to, of 15 per cent., as a cash transaction practically, would be almost exorbitant. The committee had had the benefit of an interview with Mr. Hammond, and they had agreed that that gentleman had executed most excellent terms for his own company. The committee and the Board had been unable to agree on the premises on which the success of the Holborn scheme depended. What did Mr. Hammond with all his experience think of Mr. Ward's estimate for the Holborn district? In effect, Mr. Hammond said that Mr. Ward's anticipated 3¾ per cent. would disappear, and instead of that there would be a deficit of about £3,100 per annum without making any allowance to cover the items referred to in the committee's report. He thought that that information ought to convince every impartial person that the committee's conclusions were more than amply justified—indeed, that the prospects were very much worse than had been depicted by the committee. Mr. O. Brown and Mr. Drake also disagreed with Mr. Ward. After referring further to Mr. Hammond's view as to the value of the Holborn district, he asked whether, with these facts and opinions before them, the shareholders were prepared to go into an expenditure of £15,000 or £17,000 to begin with in Holborn, to supply a possible twenty householders. As to the other provisional orders which had been obtained by the directors, the committee had refrained from expressing their views, but they had laid before them the opinions of Mr. Ward. The gist of that gentleman's view, he proceeded to say, was that Holborn was the best area the Company had, while he said that he did not consider Chelsea was a desirable neighbourhood, because most of the people living there were old ladies.

Mr. WARD: That is not correct.

Mr. PEEBLES said he would read it if Mr. Ward liked. It was a very important matter, that of the canvass of Holborn. They found that in the twenty houses mentioned they could not make more than 700 gas burners. That would be all over the houses, but there was no doubt that those who said they would take the light meant for their shops only. To introduce the electric light into the house would cost about £1 per burner, and he did not believe that the people of Holborn would be very anxious to spend £15 or £20 on fitting up the lights. He believed it was an open secret to the majority of gentlemen engaged in electric lighting that no electrical station had yet been made to pay. The conclusion of the committee was that the provisional orders were useless in the hands of the Board, and the reasons that induced that opinion were before the shareholders. They had not to consider what course their proceedings might have on electric lighting generally. What the committee had to do was, to consider what the effect would be upon the shareholders' pockets. They had come to the conclusion that unless they could get something tangible before them as business men, and not something beginning and ending with an "if," they could not advise the shareholders to go on. They felt they must be candid with them and lay before them the facts, which they had done. If, after that, the shareholders were prepared to go on, they would do so. He certainly could not see why the Company should spend more money to avert the inevitable from other electric lighting companies. He thought the shareholders of the Company had suffered quite enough by losing about £280,000 already. If, as he believed, the electric was at present commercially a failure, the sooner the public were made aware of it the better for their pockets. He wished them to understand that that was the view of an ordinary man of business, and not that of an electrician. Mr. Peebles then spoke of the costliness of adapting the Brush dynamos to low tension currents, and, with regard to the overtures referred to by the directors, said that this question was a somewhat serious matter. The committee had done all they could to get the directors to treat them as men of business. He then proceeded to criticise the action of Mr. Borrer in connection with other matters, and stated that Mr. Crompton's report, as the chairman had said, was based on Mr. Ward's estimates. Upon the directors' report he would make no comment. Doubtless they had all read the remarks of the committee thereon. The committee had fulfilled their duties, and had placed the affairs of the Company again in the shareholders' hands. The committee had told them simply the best and the worst. He concluded by moving the adoption of the report of the committee.

Mr. L. ENGEL seconded the motion.

Mr. DICKSON stated that he was the last of the old Board, and if he had consulted his own wish and comfort he would have been absent like the rest of the Board; but he had done nothing but what he considered was his duty from the very first, and therefore he had nothing to fear. Mr. Dickson afterwards referred to his action as chairman of the finance committee in defending their money and preventing unnecessary expenditure. He was not ashamed of the letter which he had written.

Mr. G. OFFOR desired to address the meeting, and stated that it was clear that the committee were decided that the Company should be wound up. (At this point the speaker was interrupted by loud cries to the effect that he was a promoter of the electric light companies—a statement which he denied, but the meeting declined to hear him further.)

Mr. TOLPUTT proposed as an amendment that the report of the committee should be received with grateful thanks, but that it should be left an open question whether they acted on their report or not.

Mr. SHIPPEY (Shippey Bros.) stated that he was not a promoter, but he candidly confessed that he wanted to be. Out of the wreck of this Company he desired to show them that they might make money. He maintained that the directors had not carried out their duties thoroughly, and stated that there was a good deal of business which they might have done but which they had not done, instancing the Brixton Station. The Company had had only two lamps running at the circuit, whereas to-day there were 46 running by other people. At present not one electric light company could pay 5s. in the £, but, he proceeded to say, there was a fine field in the future for electric lighting [question, question].

The CHAIRMAN said that the speaker was not keeping to the business. (The meeting declined to hear Mr. Shippey further.)

The CHAIRMAN stated that he would ask Mr. Crompton to give his opinion.

Mr. PEEBLES pointed out that the committee's report was before the meeting, to which there had been an amendment.

The CHAIRMAN: The question of the advisability of accepting the report or not depends on whether we were right in putting before you the Holborn district. I will ask Mr. Crompton to address you on that point.

Mr. PEEBLES said that had the chairman intended to call in an expert to address the meeting he ought to have made provision for that purpose. Mr. Crompton, with all respect to his ability, was not a shareholder.

Mr. CALLENDER, who spoke amidst a great deal of interruption, referred to negotiations which he had had with the Board, which were interfered with by the appointment of the committee. The committee, he said, had stated that the Company had a certain thing to sell, but that it was so bad that they would not touch it themselves. Yet they wanted to see if somebody else would buy it.

Mr. PEEBLES, interposing, said that the committee had stated no such thing, and the committee objected to having red herrings drawn across the track.

Considerable interruption ensued as to further hearing Mr. Callender, and

The CHAIRMAN said: Mr Callender wishes to tell you that he is prepared to find so much money to work your orders. (The meeting, however, declined to hear Mr. Callender.)

Mr. ROBERT HAMMOND stated that the subject before them, as Mr. Peebles had said, was one as to which the shareholders did not want the opinion of an electrican, but of a man of business, and it was in that capacity that he (Mr. Hammond) wished to address them. The real question for them to consider to-day was, whether the property was of any value, and whether there was any one who would buy it. He then referred to the issue of his circular, and stated that although he had not asked for proxies, various letters had reached him showing how thoroughly in accordance it seemed to have been with the feelings of the shareholders [A Voice: Your offer]. He would tell them his offer, but first he wanted to give his reasons to lead up to that matter. As to what he had stated to the committee about the Holborn lighting, he adhered to every statement. If a great trial was to be made of the electric lighting question, there must be capital. He thought that the spot where such an experiment should be made was where people were sufficiently wealthy to pay a little more for the electric light than for gas—people who had extensive picture galleries, and other valuables. He alluded to what the Hammond Company had done at Hampstead, and stated that the principles which he had indicated were absent at Holborn, where the shops were not open till half-past eleven at night and not on Sunday, while in the summer months they closed before the light was required, and in the winter months, except on Saturday, at half-past eight o'clock. He certainly did not believe that they would be willing, therefore, to pay double the cost of gas. The Hammond Company could give this Company a better price than any one else for their undertaking as a going concern. He was sure that with 100,000 lights the electric light could compete commercially with gas, and therefore he said, Do not wind up, as that might jeopardise his effort in

Digitized by Google

getting the capital which he desired to obtain in order to get these 100,000 lights. One of the reasons why he had come forward to make an offer to them was that he wished to prevent that catastrophe. As to the question of winding up or otherwise, he disagreed with the committee just as much as he disagreed with the directors with respect to the Holborn lighting. He criticised the view of the committee as to the provisional orders obtained by the Company, and said that, apart from the question of the Holborn installation, the statement of the committee as to the provisional orders struck at the root of electric lighting generally; because if the views expressed were sound electric lighting would not succeed for the next fifty years, and it was because he dissented from those views that he felt it more advisable to come to the meeting, and in person make his offer. He wanted to buy the Company's property. The committee had said that there was £26,000 which, under a winding up immediately, they would probably get. The committee also said that in addition to that £26,000 there was a lawsuit, which, if pushed to its bitter end, might become of extreme value to the Company. As to what Mr. Peebles had said about his proposed agreement with the directors, he maintained that it was a fair bargain, having regard to the circumstances existing. He held that the supply of the electric light would require a million of money in the next ten years, and there were only two or three companies who could do it, and the Metropolitan had said—Let us get one of those companies to do our work, and had said to him (Mr. Hammond), What will you do for us in return for having all our work? He maintained that when the working electric light company was on a proper basis, a profit of 30 per cent. would not be considered a big one. He considered that electricity was on as big an area as railways, and that they would be entitled to as much profit. Therefore, he said, 30 per cent. was not an outside profit, and they had said, If you give us all your work we will agree to divide all our profits with you. He considered that if the gas companies were to put down their charge to 1s. or even 6d. per 1,000ft., the electric light would in a few years be preferred to it, although people might have to pay what would be equal to 3s. per 1,000ft., on account of their preferring to breathe a pure atmosphere rather than the poison consequent on the use of gas. That was his idea of what the future of the electric light would be. He thought that the Company was divided into two camps, and perhaps he might say three—those who did not want any more paper in electric light companies and who wanted cash back, and those who believed that in the hands of a company who really knew what they were doing, 6 per cent. debentures and a certain number of deferred shares would not be half such a bad thing to them. He then proceeded to review the assets of the Company according to what the committee had said, and stated that his offer was to give them £30,000 in 6 per cent. debentures and another £30,000 in 5 per cent. deferred shares, or £30,000 in cash. He spoke of the value of amalgamation, and said that the three companies which had already amalgamated with the Hammond Company had been liquidated for £50.

Mr. BROWN observed that it was a very grave question whether Mr. Hammond was not a promoter of the Company.

Mr. HAMMOND continuing, said that they did not advertise their concessions. People came to them begging them to sell the concessions. He then proceeded to contend that liquidation would damage the assets of the Company. He had put his views before them and his terms for acquiring the company as a going concern, and so far as the action was concerned, that might be left entirely in the hands of Mr. Brown. If they thought there was anything in his offer, probably some one amongst them would move a resolution, leaving it to the consideration of the committee, and adjourn the meeting till they had thoroughly gone into it.

Mr. BROWN stated that the gist of Mr. Hammond's speech was do not wind up. He would deal with Mr. Hammond's remarks first. As to Mr. Hammond's offer, he had said he would give them £30,000 in cash, but their assets at the present moment consisted of 20,000 sovereigns; £8,000 worth of plant and machinery, £6,000 worth of stock, sundry debtors £2,000 odd, and that altogether amounted to a very considerable sum, without taking into account a shilling which had been spent on the provisional orders. The fact was, Mr. Hammond offered them paper in exchange for sovereigns. In addition to that, the shareholders had their claim against the promoters. He had just said, because he thought they ought to know it, that there was doubt whether Mr. Hammond was not himself a promoter, and he had not made that statement without very careful consideration of the matter. Mr. Hammond took a very active part in the negotiations at the formation of the Company, and until the whole matter had been thoroughly investigated he was perfectly certain that no lawyer, knowing what he (Mr. Brown) did in connection with the facts of the Company, would venture to say that Mr. Hammond was not a promoter. The only way in which it could be ascertained surely who were the promoters was a winding up, with the power of investigation which the liquidators had under a winding up, but which they had not while the Company was a going concern. The object of Mr. Hammond's circular was to stop the winding up, but where it emanated from he did not know. The only question for them as to what Mr. Hammond had said was, would they adjourn that meeting to consider his proposal, thrown at them at the last moment with, he ventured to say, an object which was not disclosed on the face of his circular? He (Mr. Brown) considered that the shareholders would best consult their own interests by carrying out what the committee appointed by the shareholders had recommended, and what the Board themselves in the circular they had sent out had also recommended—namely, to pass the first two resolutions—that was, to adopt the report of the committee, and to resolve to wind up. There was no difference between the committee and the Board on that point—the winding up of the Company. The committee said, wind it up, and realise your provisional orders if you can, without entertaining for a moment the thought of this Company, at any rate, spending any more money on them. That might be done by some arrangement being made between the liquidators and Mr. Hammond, or any other company who were willing to work the provisional orders which this Company had obtained. Mr. Hammond had spoken about amalgamation, but there could be no amalgamation without a winding up. He urged them to adopt the committee's report, and he maintained that if the directors used their proxies for any other purpose than that of the voluntary winding up of the Company, they would be guilty of a breach of faith to those shareholders who had sent them. In answer to a question, Mr. Brown said he was bound to admit there was a clause in the Brush licenses under which the licenses became forfeited if the Company went into liquidation; but he held that they would really forfeit nothing. If they had to deal at that meeting with the question of the promotion of the Company, he would have to deal a little with that clause to show them what an utter fraud and delusion it was. The question of winding up was, in his opinion, essential. His opinion was, that the promoters were liable for the amount of £200,000. That was the view that he expressed at the last meeting, and it had been strengthened since by what had transpired, which he proceeded to particularise. In conclusion, he again maintained that it was essential to wind up, and stated that within the last few days the chairman of the Committee had had a communication from an intimate friend of one of the promoters suggesting the desirability of coming to terms.

The CHAIRMAN said he wished to ask Mr. Brown one question. He was told that the loss of the licenses resulting from liquidation would prevent them from bringing an action against promoters for rescission of contract, as, in that case, they were advised that they would be called upon to return intact that which was sold to them.

Mr BROWN said he had considered the question, and he was bound to say that he had all along felt that bringing an action for rescission of contract would be a very great mistake. The main attack would probably not be upon the people who figured as vendors. They could not say that a corporate body had committed fraud, but he could put his fingers upon individuals in this case—he could put his fingers on the individuals who, in his opinion, did commit the fraud, and if they brought an action for fraud the measure of their damage was the loss they had sustained by being induced to buy something by fraudulent representation—something that was not worth what it was represented to be.

Mr. WM. ABBOTT asked what would be the position of the shareholders with a liability of £200,000 on them, supposing the lawsuit went on and exceeded the assets. He proposed for their consideration that a resolution should be immediately passed to reduce the capital from £500,000 to £200,000, and that a dividend of 3s. a share should be paid so that the shareholders could know the exact amount that could be spent and no more.

Mr. BROWN: Shall I answer that question? (Voices of "No" and "Yes.")

The CHAIRMAN stated that he thought the meeting would like him to bring before them a point that came under his notice just before the meeting. It affected the value of their assets, and he believed that they looked forward to being able to realise the provisional orders. Mr. Meysey Thompson and the Board of Trade had said: "If your friends think they are going to carry on this business under a liquidation they are mistaken. The Board of Trade would not consent to give an extension of time to a company in liquidation, or to carry on the work in that position, even if it were a working liquidation." That meant that the orders would lapse. This was not said officially, and they must take it for what it was worth, but we have been definitely told by the Board of Trade that no extension of time will be given for any provisional order unless the deposit on the Holborn provisional order is paid, and the charge on the capital figured.

A SHAREHOLDER: We do not want them.

Another SHAREHOLDER: That is another red herring.

The CHAIRMAN then put the motion of Mr. Peebles, which was carried with one dissentient.

Mr. BELL moved the second resolution, as follows: "That, in the opinion of this meeting, it is desirable that the Company should be wound up, and that the same be accordingly wound up voluntarily." His desire was that the disgorgement should be carried on to the full extent of the letter.

Mr. C. P. WHITELEY seconded the motion.

The CHAIRMAN put the motion, and it was carried with two dissentients.

Admiral INGLEFIELD proposed the third resolution, as follows: "That Alexander Peebles, Admiral Sir Edward Augustus Inglefield, Lawrence Engel, John Hamlyn Borrer, and Charles Tottenham be, and they are hereby appointed to be liquidators of the Company, with power to continue to carry on the business of the Company, in so far as they may consider requisite or necessary for utilising and realising to the best advantage the assets of the Company, including the provisional orders." He stated that the feeling of the committee was that they could not act with two of the gentlemen mentioned in the resolution, and it was for the meeting to say who should act with the committee.

Mr. BROWN seconded the motion pro forma. He criticised certain proceedings which he said had been taken by Mr. Borrer in connection with the Company's affairs, and alluded to the step which he (Mr. Brown) had taken of filing a petition. By the exclusion of two of the gentlemen mentioned in the resolution there would remain three hard-headed men of business, and he ventured to say that they might properly be entrusted with the liquidation of this unfortunate affair. If that was the view of the meeting, he would ask them to move an amendment to the resolution, as the committee, after the course taken by Mr. Borrer and Mr. Tottenham, had requested him to say that they could not act with those gentlemen.

Mr. POOL moved an amendment to the effect that the names of Mr. Borrer and Mr. Tottenham be left out of the resolution, and the name of Mr. Charles Bell substituted.

The amendment having been seconded,

The CHAIRMAN said: Just let me ask you first if you will give me as

Digitized by Google

fair a hearing as you have given to Mr. Brown. I was abroad at the time, but the committee assented first about the proceedings as to going on with the Holborn order. If it was a good thing that that should be gone on with, it was our duty to go on with it. We took your meaning at the last meeting as approving our view. [Oh !] It was said that we had got that on mistaken grounds. [Interruption.] Well, gentlemen, if you do not wish to hear my reply, I do not wish to force any truth down your throats. I will now put the amendment, which he proceeded to do, and declared it carried.

It was afterwards moved as a substantive resolution, and declared carried.

Mr. ANDREAE moved, and Mr. STEWART seconded, the fourth resolution, as follows :—"That the liquidators of the Company be, and they are hereby authorised to take such proceedings as they may be advised in connection with the promotion and formation of the Company and the purchase of the licenses, with full power to compromise, upon such terms as they may think fit, any such claim, or any other claim, which they may, in the course of the winding up, be advised to make against any company, firm, or person."

The CHAIRMAN having put the motion, declared it carried.

On the motion of Mr. PEEBLES, the fifth resolution was passed, as follows :—"That the said liquidators are hereby authorised to transfer or sell all or any of the assets of the Company to any other company, formed or to be formed, and to receive in compensation, or part compensation, for such transfer or sale, shares or other interests in any such other company, or to receive in compensation, or part compensation, for such transfer or sale, the right to participate in the profits of, or receive any other benefit from any such purchasing company."

With regard to the sixth resolution (fixing the remuneration of the liquidators) it was decided that the matter should be left over until the next meeting.

The seventh resolution was as follows :—"A resolution or resolutions to authorise the payment out of funds of the Company of the expenses incurred by the committee in and about their investigation of the affairs of the Company, and, if thought fit, remuneration to the committee for their services." The resolution was divided into two parts, by the first of which a sum of £400 was voted to the committee for their expenses in the investigation, and by the second part a sum of 400 guineas was voted to them as remuneration for their services.

The eighth resolution was as follows :—"A resolution as to the course to be taken by Alexander Peebles, Admiral Sir Edward Augustus Inglefield, Lawrence Engel, and George John Frederick Andreae, with reference to the petition presented by them."

Mr. BROWN asked the meeting to leave this question in the hands of the petitioners, his opinion at present being in favour of a supervision order.

The meeting consented to this course.

Two other resolutions were passed, prescribing the time and place for the holding of a further general meeting of the Company for the purpose of confirming and making special within the meaning of the 51st section of the Companies Act, 1862, any of the resolutions which might require confirmation as special resolutions in order to give them validity ; and prescribing the manner in which notice of such further meeting was to be given to members of the Company.

The proceedings (which lasted three hours) terminated with a vote of thanks to the chairman, who, in reply, expressed a wish that the meeting had been more ready to hear both sides.

## UNITED TELEPHONE COMPANY (LIMITED).

An extraordinary general meeting of the shareholders of this Company was held on Tuesday, at the City Terminus Hotel, Cannon-street (Mr. J. Brand in the chair), for the purpose of confirming the resolution passed at the extraordinary general meeting of the Company held on the 22nd ult., viz. :—"That the Bill which is proposed to be introduced into Parliament in the ensuing Session, intituled 'A Bill to afford to the United Telephone Company (Limited) additional facilities for telephonic communication in the metropolis and for other purposes,' is approved subject to such additions, alterations, and variations as Parliament may think fit to make therein." The resolution having been read by the secretary, was proposed by the chairman, seconded by Mr. J. W. Batten (director), and carried unanimously.

THE TELEPHONE IN VENEZUELA.—Regarding the Inter-Continental Telephone Company, in which Boston capital is largely invested, advices just received per steamer "Caracas," from La Guayra, Venezuela, show that the company's business is rapidly increasing. The trunk line between Caracas and La Guayra was completed on the first day of January, as anticipated, and its first day's business was fifty-four telegrams, or rather "telephonagrams." La Guayra being the port of entry to Caracas, the capital of Venezuela, a large business between the two cities is assured. The system already embraces 190 subscribers at Caracas and sixteen at La Guaya, paying a monthly revenue of 1,030dols., fifteen more subscribers await connection at La Guayra and thirty-five at Caracas, besides which applications for exchanges at Valencia, Porto Cabello and other points are under consideration. The present revenue of the company is equal to 6 per cent. on the entire capital.—*Electrical World.*

UNDERGROUND WIRES IN NEW YORK.—A bill has been introduced in the New York State Senate, providing that in all cities of 500,000 or more inhabitants, telegraph wires and cables of all descriptions shall be placed underground before November, 1885.

## NOTES.

ELECTRIC LIGHTING IN AMERICA.—Salt Lake City now boasts 145 arc lamps in its streets.

DIVIDEND.—The New York Edison Company for isolated lighting has declared a dividend of 4 per cent.

LONDON CENTRAL ELECTRIC RAILWAY BILL.—This Bill was read a second time in the House of Commons on Tuesday last.

THE UNITED TELEPHONE COMPANY'S BILL.—The conservators of the River Thames have presented a petition against this Bill.

BRAZILIAN SUBMARINE TELEGRAPH COMPANY.—The traffic receipts of this company for the week ended 15th February amounted to £3,152.

ACCUMULATORS FOR TELEGRAPHY.—Accumulators have, according to a contemporary, been tried in the telegraph office at Strasbourg, with good results.

CABLES INTERRUPTED.—The cables between St. Vincent and Barbadoes, between Trinidad and Demerara, and between Maranham and Para are interrupted.

BOOK RECEIVED.—"I Recenti Progressi nelle Applicazioni dell' Elettricita," di Rinaldo Ferrini, Professore nel R. Istitute Tecnico Superiore di Milano. Published by Ulrico Hoepli, at Milan.

EARTHQUAKES IN ASIA.—The *Turkestan Gazette* states that as many as 90 distinct shocks of earthquake have been felt at Oosh, Central Asia, since November 14. Other shocks have also recently occurred at Viernoe and Tashkend.

ELECTRIC LIGHTING IN WORKS.—The works of M. Watin at Marcinelle, in Belgium, are now lighted by thirty incandescent lamps. The installation has been carried out by the Compagnie Belge et Hollandaise d'Electricité of Brussels.

ELECTRIC LIGHTING AT CANNES.—The lighting of the Boulevard Cannet at Cannes by means of Brush lamps has proved so satisfactory that this system is to be extended shortly to a new boulevard which is in course of construction.

SALES OF TELEPHONE APPARATUS.—It is stated that the Continental Telephone Company of Boston, U.S., has sold 1,000 sets of instruments since the 1st December last, and that from May 1, 1883, to December 1, 1883, it sold over 2,800 sets.

WIRES IN CHICAGO.—The City electrician of Chicago, and other officials, are now visiting the chief cities in the United States for the purpose of examining all the underground fire-alarm and telegraph systems, with a view to establish some system in Chicago.

TELEPHONY IN PORTUGAL.—A Lisbon paper says:—"The Edison Telephone Company in Lisbon are extending their exchange lines to Taewend and Povoa de Santa Iria. The work is progressing with extraordinary rapidity under the able direction of Mr. Alfred Thompson."

THE CABLE FLEET.—The Eastern Telegraph Company's ss. "Chiltern" has been chartered by Admiral Hewett to take troops from Suakim to Trinkitat. It will be remembered that this vessel has been engaged in the recent cable work in the Red Sea, which has proved of so great service to our Government.

THE OLDER ELECTRICITY.—Professor Tyndall will give the first of a course of six lectures on "The Older Electricity, its Phenomena and Investigators," at the Royal Institution on Thursday next, February 28th. The remaining five lectures are to be delivered as follows:—March 6, 13, 20, 27, and April 3.

THE TELEPHONE CASE AGAIN.—Notice has been given by Messrs. Davidson and Morriss, solicitors for Messrs. Harrison, Cox-Walker, and Co., of their intention to appeal to the House of Lords against the decision of the Court of Appeal in the case of the United Telephone Company *v.* Harrison, Cox-Walker and Co.

THE BELL TELEPHONE IN AMERICA.—The United States Government have agreed to pay the American Bell Telephone Company a royalty on all telephones manufactured by the United States Signal Service and used by the Government. The company claims that such instruments are infringements of the Bell patent.

TELEGRAPHIC COMMUNICATION WITH COREA.—A cable has been laid by the Great Northern Telegraph Company, connecting the island of Kinshiu (Nagasaki) with Tsusima and Fusan (Corea). The rate to Tsusima and Fusan, which stations were opened on the 15th instant, is from all stations in the United Kingdom 10s. 11d. per word.

ELECTRIC LIGHTING FOR BALLS.—On the occasion of a ball given a few days since by the Belgian Minister of Finance at Brussels, the rooms were lighted by incandescent lamps supplied by the Compagnie Générale d'Electricité. The current was furnished by accumulators supplied by the Compagnie Belge et Hollandaise d'Electricité.

SOCIETY OF TELEGRAPH ENGINEERS.—At the meeting of this society to be held on the 28th inst., the following papers will be read:—"On Some Prejudicial Actions in Dynamo Machines," by B. W. M. Mordey, Associate; "On the Effects of Induction in Alternate Current Machines," by Professor George Forbes, F.R.S.E., Member.

EXPERIMENTS IN ELECTRIC LIGHTING.—Experiments are about to be carried out at Wimbledon under Mr. W. H. Preece, F.R.S., to determine the relative efficiency of arc and incandescent lamps for street lighting. The experiments will also include the distribution of the light in each case, so as to obtain the greatest efficiency and economy.

ELECTRIC LIGHTING IN AMERICA.—The City Council of Savannah, Georgia, have awarded the contract for lighting the city to the Brush Electric Lighting and Power Company for three years. The city pays the company 18,000dols. annually, and the company proposes to erect towers or masts in such parts of the city as will enable them to light the whole of it.

LONG DISTANCE TELEPHONY.—Arrangements are being made by the Southern New England Telephone Company to establish a through telephone line between two cities in the United States, which will be over 200 miles long. The American Bell Telephone Company are also carrying out experiments with the view of establishing a through line between New York and Boston.

THE TELEPHONE FOR BUSINESS PURPOSES.—Messrs. Johnson and Phillips, of 14, Union-court, Old Broad-street, E.C., and Victoria Works, Charlton, S.E., inform us that their City offices are now in direct telephonic communication by private wire with their works at Charlton. They are also subscribers to the United Telephone Company's system, so that orders can be telephoned right through to Charlton, thereby saving a great deal of time.

THE NEW RAILWAY UNDER THE PARKS.—After Easter, the Earl of Belmore intends to ask in the House of Peers

Digitized by Google

whether, in view of the difficulty, if not impossibility, of properly ventilating underground railways without openings into the outer air, the Government will consider the propriety of making the assent of Parliament to the proposed new railway under the public parks contingent on the company undertaking to work the line by electric energy and not by steam.

THE TELEPHONE AND THE PUBLIC.—At a special meeting of the South of Scotland Chamber of Commerce, held last week at Galashiels, it was agreed to approve of the reduction of the rates charged for telephonic communication, and that the Postmaster-General be requested to grant licenses on such terms and royalties to responsible persons or companies for the establishment of telephonic exchanges and trunk lines as may be necessary to carry on such exchanges at the smallest cost to the public.

H.M.S. "CROCODILE."—The "Crocodile," Indian troopship, Captain Carr, which is about to leave Portsmouth for India, was brilliantly illuminated on Wednesday night by means of the incandescent lights which have been fitted up by the Edison and Swan Company, and being found to work satisfactorily will be used on her next voyage. All parts of the ship, including the bunkers, are lighted, 402 lamps being employed. The dynamos are of the Edison-Hopkinson type, and are driven by two Brotherhood engines.

THE BUDAPEST EXHIBITION.—With reference to this exhibition, a notice of which appeared in a recent issue, we are informed that the commission, at the request of several foreign exhibitors, have prolonged the period of application from the end of February, as originally fixed, to the end of April, 1884. Further, that the general rules have been so far modified that one third of the rent for space may be transmitted to the general commission at Budapest, on the filling up of the application for admission, one third by the end of June, 1885, and one third before the removal of the objects exhibited.

SHIP LIGHTING.—The "Massilia" was launched from Messrs. Caird and Co.'s shipyard at Greenwich last week. She is a steamer of 5,000 tons, and has been built for the Peninsular and Oriental Company. Her dimensions are :—Length, 420ft.; breadth, 45ft.; and depth, 37ft. She will be fitted with engines of 5,100 horse-power, cylinders 56in. and 105in. in diameter, with a piston stroke of 6ft., and a condensing surface of 10,000 square feet. With these a speed of 16 knots is expected. The "Massilia" is to be lighted throughout by the Edison-Swan Company, and fitted with Binko's electric signalling apparatus.

THE STORM IN JANUARY.—At the last meeting of the Royal Meteorological Society, Mr. W. Marriott read a paper on the great storm of January 26th. He said this storm was remarkable for its violence and large area, as well as for the unprecedentedly low barometer reading at its centre. Thunderstorms occurred on the south-eastern side of the depression, and travelled across the country at the rate of 30 miles an hour. From an examination of previous records it appeared there had never before been so low a barometer reading as 27·332 in., so that this storm might be considered as one of the most remarkable that had occurred in the British Islands.

ELECTRIC LIGHTING IN JAVA.—The palace of the Sultan of Djokjakarta has, we are informed by a Soerakarta correspondent, been lighted by electric lamps. Swan lamps to the number of 196 are used, together with four arc lamps. Siemens's dynamos supply the current, and are driven by semi-portable engines. The installation was effected under the supervision of Mr. J. V. Zwieter, the materials being supplied by the Dutch Electric Light Company of The Hague. The Prince of Soerakarta is about to have his palace and gardens lighted by electric lamps, several factories are to be lighted by the same means, and altogether our correspondent speaks enthusiastically of the future of the electric light in Java.

DEATH OF THE COUNT DU MONCEL.—The news contained in the following telegram from the Paris correspondent of the *Daily News*, dated Monday last, will be read by all connected with electrical science with unfeigned regret and sorrow :—"The Comte du Moncel died suddenly on Saturday night, the 16th inst. He was one of the first in France to bring electrical science within the reach of unscientific readers." A short reference to this able writer will be found in another part of this week's issue. We hope to be able to furnish our readers with some details of the Count du Moncel's life and work on a future occasion. A funeral service was held in the Church of Saint Louis d'Antin, Paris, and the body was subsequently removed to Leibsey, the count's country residence, for burial.

A TELEGRAPHIC CONTEST.—On Friday and Saturday last a contest took place at the West London Telegraph Schools, Uxbridge Road, W., as to who was to be considered the fastest and best Morse transmitter in this country. Many operators from all parts of the Kingdom entered, and the competition was an interesting one. Eventually Mr. J. Chapman, of the Stock Exchange, was adjudged the winner, Messrs. J. Dennett and A. Brooker, of the General Post Office, coming second and third. Mr. Chapman accordingly took the silver cup offered by Mr. Lynd, the organiser of the competition. We believe that it is intended to make an annual event of this friendly contest among the telegraphic fraternity. The word fraternity reminds us by its inapplicability that ladies were among the competitors.

THE SAIGON CABLE.—The Governor of Cochin China telegraphed to the French Minister of Marine as follows on the 18th inst. :—"Having been received with the greatest cordiality at Cape St. Jaques on the 'Calabria,' I invited the English engineers of the submarine cable to Saigon. At a banquet I drank to the success of the cable, and proposed 'The Health of the Queen of Free England.' Mr. Riddle, the chief engineer, returned thanks, and drank to France, the President of the Republic, and to the success of our civilising mission in Indo-China." The President of the Republic has received a telegram from the King of Annam, conveying his congratulations on the laying of the submarine cable, which, he said, would be the means of forming a more intimate alliance between the two nations.

BRONZE WIRE.—The following reports have been made on the bronze wire made by the Ansonia Brass and Copper Company of New York. Mr. G. A. Hamilton, of the Western Union Telegraph Company, reports the following as the result of his tests :—Weight per mile, 110·9lb; resistance, temperature 75deg. F., 8·162 ohms; weight per mile ohm, 905·5 ohms; conductivity (compared with pure soft copper), 99 per cent.; breaking strain, 360lb. to 365lb.; elongation, 2 to 4 per cent.; twists in six inches, 20·5 to 37·5. Professor C. F. Brackett, of Princeton, gives the following figures resulting from a different series of tests :—Length, 102·4400ft.; diameter, 0·0838in.; resistance at 60deg. F., 0·1526 ohm; resistance of standard (reduced to same diameter), 9·15104 ohms; conductivity as compared with chemically pure copper, 99 per cent. (98·98).

TELEGRAPHIC EXTENSIONS IN LIVERPOOL AND MANCHESTER.—The proposed introduction of the sixpenny telegrams will necessitate a good deal of work in Liverpool and Manchester. Thus, in Liverpool eight additional pneumatic tubes

Digitized by Google

will be constructed between the exchange, &c., and the head office, and more than a dozen of the local offices will receive new wires. Outside of the city three new wires to London and a share of a fourth will be provided; three new wires, duplexed, to Manchester, and one each to Belfast, Birmingham, Blackburn, Bristol, Carlisle, Glasgow, Hull, Leeds, and Newcastle will also be put up. In Manchester, besides the wires to London and Liverpool referred to above, there are more than a dozen new circuits to important towns, and about the same number of local additions or improvements.

ELECTRIC LIGHT IN IRONWORKS.—On Friday, the 15th inst., the members of the Leeds Association of Foremen Engineers and Draughtsmen, to the number of about 100, visited the works of the Leeds Forge Company (Limited), at Armley. Mr. Samson Fox, C.E., the managing director, and Mr. W. Fox acted as guides to the visitors, and fully explained each process, sparing no pains to make the visit a pleasant one. The operations by which the Leeds Forge Company make Fox's well-known corrugated furnace tubes were explained and shown. The flanging shop has been lighted for some time past by electric lamps, which were erected under the superintendence of Mr. Wilson Hartnell, of Leeds, and supplied by Crompton and Co., Chelmsford. The whole area of the shed—about 1½ acres—is lighted by arc lamps, which have proved a great success; in fact the managing director stated that this mode of illumination costs less money, all things considered, than Leeds gas at the present time.

TELEGRAPHIC COMMUNICATION WITH HOLLAND.—A correspondent of a daily paper writes:—"For a considerable time the telegraphic communication between this country and Holland has been very defective, owing to the breakage of the two cables between Lowestoft and Zandvoort, on the Dutch coast. This has caused much inconvenience not only to English and Dutch merchants, but also to the German public, who largely availed themselves of the two cables for transit messages. The German Postmaster-General has in consequence already lodged a complaint with the British postal authorities. It is understood that an address to our Postmaster-General is now in circulation in the city to support the efforts of the German and Dutch Governments to get the present unsatisfactory state of affairs remedied, the two cables belonging to the British Government being worked by the Submarine Telegraph Company. Some of the leading London merchants and bankers have already signed the address, which is shortly to be forwarded to the Postmaster-General."

OVERHEAD WIRES IN WASHINGTON, U.S.A.—In the annual report of the Engineer Department for the District of Columbia, U.S., ending June 30, 1883, Captain Greene says:—"Telegraph poles and wires have more than doubled in the last three years. There are now 2,623 poles, 79 miles of line, and 767 miles of wire in the city, not including the house-top lines, which would probably add 150 miles more." After reciting the conditions upon which a number of these new lines were constructed, and referring to the efforts, commenced in 1880, to put these lines underground, Captain Greene says that "two applications from underground companies have been granted—one to the Standard Underground Cable Company, a company which manufactures cables only, and is not a telegraph company; the second is to the Postal Telegraph Company, who have the exclusive right to construct conduits for electrical wires on 14th and 'T' streets, provided other companies can lay their wires therein at a fair rental. The conduits of the latter company are constructed of brick masonry 16in. square in cross section with a stone or iron cover, in which the cable lays. Their utility had not yet been tested when this report was made."

THE CAMBRIAN FINE ART EXHIBITION, CARDIFF.—This exhibition, which opened on the 14th inst., is lighted by arc and incandescent lamps, fitted up by the Great Western Electric Light and Power Company, the current being supplied from the company's lighting station in Working-street. There are fifty-six incandescent lamps attached to handsome electroliers and brackets placed at carefully determined distances throughout the halls, and eight arc lamps suspended from the ceilings and the walls. The effective arrangement of the incandescent lamps is greatly admired, and the arc lamps are burning steadily. This result is the more satisfactory as the Brush machines supplying the current are working the two town circuits. On these circuits are arc and incandescent lamps at the Theatre Royal, the *South Wales Daily News* Office, the Philharmonic Music Hall, many of the more important business establishments, and the circus. The company is about extending its circuit so as to supply the Great Western Coffee Tavern and other public and private establishments. The whole of the installation has been carried out by the superintendent of the lighting station, Mr. B. Deakin.

THE PRODUCTION OF ELECTRICITY BY CONDENSATION OF AQUEOUS VAPOUR.—Herr S. Kalischer has examined this problem, and published the result of his investigations in the *Annalen der Physik und Chemie*, of which the following abstract is given in the February number of the *Journal* of the Chemical Society:—"The production of electricity by condensation of aqueous vapour presents a problem of considerable meterological importance as regards the origin of atmospheric electricity. It is, however, probable that the production of electricity observed is in most cases due to the friction between the water particles and the condensing surface. In this paper the problem is examined experimentally by means of an apparatus which permitted the condensation of aqueous vapour by cooling. It consisted essentially of a series of beakers filled with ice, and covered externally with tinfoil; the beakers were placed on a plate of galvanised iron connected with a quadrant electrometer, and the whole combination was enclosed in a metallic box. Although deviations of the needles of the electrometer were observed, yet they were of the same magnitude and direction whether the beakers were filled with ice or not; and, secondly, they were sometimes in one, and sometimes in the other direction. Other experiments are described in which air was compressed in, and then allowed to expand from, a vessel resembling the electric egg, the metallic stopcock of which was in connection with a quadrant electrometer. But in this case, although a pressure of 25 atmospheres was used, and the aqueous vapour fell in the form of fine dew on releasing the pressure, yet there was no development of electricity."

ELECTRIC LIGHTING AT THE BANK OF ENGLAND.—In the course of last year the directors of the Bank of England, who had under their consideration for some time the expediency of adopting electric lighting throughout the building, resolved as a first step to entrust to the Electrical Power Storage Company the fitting up with incandescent lamps of the private drawing office, the bill office, and a portion of the securities vaults, making a total of 150 lamps. The work has now been completed, and a few days since the deputy governor (Mr. J. P. Currie), accompanied by several of the directors, made an inspection of it, and expressed their satisfaction with the result. The Faure-Sellon-Volckmar accumulator system has been adopted. A dynamo charges 55 cells, which are sufficient to provide the 150 lamps at all times during their ordinary service, or in case of fog or other unforeseen circumstances, to give a

Digitized by Google

whole day's lighting without working it. Swan lamps are used, which are fixed on specially-designed brackets attached to the present gas fittings, each lamp having a switch arrangement exactly resembling a gas-tap, so that the control over the lighting is as complete as under the old system, with the advantage that when desired the whole may be lit or extinguished in a second. The dynamo is of the "Victoria" type, made by the Anglo-American Brush Corporation. Its E.M.F. is 120 volts, and it is capable of giving a current of 60 amperes. Andersen's cut-outs are provided, which will break the circuit if any excess of current passes. We illustrated this cut-out in our articles on the Vienna Exhibition. The lights in the vaults, where the securities of the Bank's customers are kept, are much appreciated by the *employés*, as the atmosphere is far purer than when gas was used. The whole of the installation was carried out by Mr. F. Thornton, manager of the Electrical Power Storage Company's Works.

LANCASHIRE AND CHESHIRE TELEPHONE EXCHANGE COMPANY.—The *employés* of this company held a *soirée* in Manchester on Saturday evening, when contingents arrived from Liverpool and North Lancashire districts to meet the head-quarters staff in Manchester, the total number present being about two hundred. Three rooms in the company's offices in Faulkner-street were very tastefully decorated as tea rooms for this occasion, and tea being over, an adjournment was made to the Lecture Hall of the Athenæum, where, after a few words of advice and encouragement from the chairman of the company, Mr. Charles Moseley, a programme consisting of songs, instrumental music, and dancing was gone through, all present appearing to thoroughly enjoy themselves. The evening's entertainment was brought to a close at eleven o'clock to enable those coming from a distance to be in time for trains back. In the ante room of the Athenæum a number of telephones were connected with the Royal and Prince's Theatres, and afforded much amusement to those who desired to listen to the performance of the pantomimes. The chief officials of the company were present, including Mr. Kenneth MacIver, secretary and general manager; Mr. T. S. Clark, engineer; Mr. R. H. Claxton, manager, Liverpool district; Mr. J. A. Chambers, manager, North Lancashire district; Mr. J. Poole and Mr. J. H. Haworth, electricians. Though this telephone company has only been established some four and a half years, its operations are on a very large scale, and embrace the whole of Lancashire, Cheshire, and North Wales. A fair idea of the work done by the company may be gathered from the fact that, in addition to the two hundred present at the *soirée*, and which chiefly consisted of members of the indoor staff, the company employs about one hundred and fifty persons on the outdoor service of constructing and repairing telephone lines. The success attending the first *soirée* has been so gratifying that, we are given to understand, it has been decided to make the occurrence a yearly one.

THE TELEPHONE LITIGATION IN AMERICA.—The case of the American Bell Telephone Company *v.* the Peoples' Telephone Company does not appear to be settled yet. The latter own the patents of Daniel Drawbaugh, who, they say, made and used a telephone as far back as 1867. The case for the American Bell Company is that, even though he might have invented the telephone prior to Bell, he subsequently abandoned it, and therefore is not entitled to patent protection. The case is one of considerable interest, and will probably definitely settle several other patent suits now pending in the States, in which the McDonough, Baxter, and Robertson patents are concerned, as well as other suits nearer home. *Bradstreets*, a well-known New York paper, puts the case very clearly when it says:—"If Drawbaugh is finally adjudged the inventor of the telephone, the McDonough as well as the Bell patents become invalid, and if it be held that there was abandonment on the part of Drawbaugh he cannot secure a patent, and the telephone therefore becomes public property. It must not be supposed, however, that this will throw the telephonic field open to all comers. The telephone itself is but a part of the complete set of appliances that constitute a practicable commercial telephonic system. Without the central station to which the wires of all subscribers run, and at which different subscribers are constantly being put in communication, telephonic communication would be impossible except by separate wires from every user to every other user. This would demand an outlay in the shape of plant so great as to prohibit the use of the telephone entirely. Both the McDonough and the Bell interests claim to have patents, without infringing which no practicable telephone exchange can be operated. After the settlement of the question of priority in the invention of the telephone, the contest will very probably be carried into the question of mutual infringement of these devices, unless the contestants in the meantime reach a mutually satisfactory adjustment of their claims. This latter seems the most probable upshot of the matter. This will leave the present distribution of the telephonic forces practically unchanged, and the question of improved telephonic service at reduced rates to be determined by the business interests of the companies engaged in the business." There are rumours in the States that the Drawbaugh telephone is a creation of far later date than its friends would have known, and very unkind things are being said of Daniel Drawbaugh himself. How far these can be weighed in the balance against the overwhelming evidence that has been given in his favour we do not know. At any rate the issue of the case will be looked for with anxiety by all interested in telephony.

THE SIXPENNY RATE EXTENSIONS.—Speaking of the extensions necessary to meet the proposed sixpenny rate for telegrams, a Scotch paper says:—"In extending the connections of London with the principal towns of the kingdom, the operations are of a somewhat gigantic nature. Above ninety towns are enumerated, but as some of these refer to wires which are to serve two or more places, the actual additions to the wires number about eighty. These run to the chief towns in every part of the kingdom, from Aberdeen in the north to Exeter in the south; and the only exception is Ireland, which is, strangely enough, absent from the list. While Scotland absorbs seven new wires (Edinburgh two, Glasgow three, Aberdeen and Dundee one each), we see no reference to Dublin, or Belfast, or Cork, as requiring new wires to London, the only change recorded for Ireland being that the Dublin wires to London are hereafter to be worked duplex. All the new wires stretching from London are to be so worked, and their distribution appears to be general. Liverpool gets three new wires, Manchester two, and Birmingham two; while an eighth wire is being put up for news purposes, working from London to all three towns. The only other places obtaining more than one new wire are Brighton, Leeds, Newcastle-on-Tyne, and Newmarket. The other towns embraced are such as Aldershot, Andover, and Aylesbury, at the beginning, Hull, Ipswich, and Jersey in the middle, and Wolverhampton, Yarmouth, and York at the end of the alphabet, these names giving a fair idea of the nature of the places to be so strengthened in their wire connection with London. As regards Scotland, we have seen that it obtains a fair share of the new London wires, and many other important additions to its telegraph system are being made. Edinburgh, as mentioned, obtains two new duplex wires to

Digitized by Google

London, and it also obtains a new circuit to Manchester, and improvements in its working to Liverpool and Newcastle. A large number of local changes will be made, including new wires to Kelso, Musselburgh, and Linlithgow, the duplexing of wires to Perth, Stirling, and Kirkcaldy, and certain other re-arrangements, including new wires to some of the more important branches within the city. Glasgow, as becomes its size and commercial character, figures largely in the new scheme. Its three new London wires are supplemented by one new wire each to Liverpool, Leeds, Dundee, Oban, Kilmarnock, Falkirk, Alloa, &c., with several re-arrangements which give a number of towns better accommodation. There are also several urban alterations and improvements of an important kind, pointing to the cultivation of local traffic. Throughout the length and breadth of Scotland the alterations are numerous, chief amongst them being a change described some time ago in our columns, whereby Lerwick will obtain a new wire working direct to Aberdeen, Wick having also a new wire, so that the existing single wire used by Kirkwall and Lerwick, and working no farther south than Wick, will be divided at Kirkwall, giving that place a direct and independent access to Inverness and the south; while the present wire north to Lerwick will be available for local traffic between the islands."

THE TELEPHONE FOR PORTSMOUTH.—On Wednesday last a deputation waited on Mr. Fawcett, the Postmaster-General, with the object of laying before him the subject of telephonic facilities for Portsmouth. The deputation consisted of the members for Portsmouth, the Hon. T. C. Bruce and Sir H. D. Wolff, with several members of the Town Council and local Chamber of Commerce. With Mr. Fawcett were Messrs. Stevenson Blackwood and Hunter. Mr. T. C. Bruce, M.P., in introducing the deputation, said they were anxious to have similar facilities in Portsmouth to those granted to Liverpool, Bristol, Birmingham, and other large places. There were certain material differences between the conditions imposed by the Post Office for the use of telephones and those offered by the United Telephone Company. The former charged £14 10s. for a half mile, and £18 for over half a mile, while for any distance under a mile the company would only charge £12. They would also erect convenient exchange centres at various points, instead of only having one office as the Post Office did. Mr. Hall and Mr. King spoke respectively on behalf of the Chamber of Commerce and Town Council, and asked for the same privileges for Portsmouth as were granted to Manchester and Birmingham.—Mr. Fawcett, in reply, said that it was not necessary to discuss the relative advantages or disadvantages of telephonic communication being applied to any town by the Post Office, or through private enterprise, such as they advocated. It would be possible for him to point out advantages, that had not been mentioned there, which he thought the public enjoyed from having telephonic communication supplied through the Post Office. In proof of that he might refer to the important fact that in the town of Newcastle, where there was both a telephonic exchange communicating with the Post Office and one belonging to a private company, they were doing a large amount of business, and subscribers to the Post Office Exchange were considerably increasing. The inhabitants of Newcastle would consider it a peculiar hardship if they were deprived of those advantages, such as secresy, and the more easy connection between telephones and telegraphs that could be carried out in a postal office. He would not discuss those advantages or disadvantages, as the policy he had always maintained was not to enforce telephonic communication being supplied by the Post Office in any town or any community which would rather have it supplied through private enterprise. They had a certain number of telephonic exchanges belonging to the Post Office, and he thought experience would show the best way of supplying telephonic communication. If it should be proved that private enterprise was the best means, he would be the last to regret it; but if, on the other hand, the public came to them and said they would rather have telephonic communication supplied through the Post Office, he considered that their department, being the servant of the public, was bound to supply any service that was demanded so far as practicable. He should let the question be determined, as it were, by the proved wants of the public. The important question raised by their deputation was not whether the supply should be through the Post Office or private enterprise, but what were the conditions necessary to attach to a license given to a private company, keeping properly in view the interests of the public, and the interests of the Exchequer, which of course he was bound, as far as possible, to guard. He understood their contention to be that he had allowed telephonic licenses to be given to certain towns, and that at a certain period he introduced different conditions, and said that with regard to towns to which licenses had not been granted new conditions would be enforced. That was no doubt correct. After the trial in which it was decided by two eminent judges that telephonic communication was infringing the telegraphic monopoly, which had been obtained at enormous cost to the taxpayers, the question arose as to what was to be done with those companies which were infringing the legal rights of the Post Office? It was thought, as the infringement was unintentional, that it would be hard for the companies to forfeit the money they had expended in bringing an important scientific discovery into working operation; and therefore such companies as had established exchanges were allowed to continue, under certain terms thought necessary to protect the interests of the revenue. After that had been in operation for two years, it was said that he was giving a certain monopoly to certain companies. Other towns and companies applied for licenses, and he had to consider whether he should continue his policy, or adopt what he might call free trade under proper conditions so far as his department was concerned. After careful consideration he resolved to adopt the latter, and said that any town, whether the Post Office had established an exchange in it or not, might have a license for a company under certain conditions, which would give proper protection to the public, and enable the department to come in at any moment to protect the interests of the public with regard to telephonic communication, in case any of the companies to which licenses had been given had taken improper advantage of the privileges conferred on them. For this reason alone the clauses to which objections had been raised had been inserted in the agreement. The deputation said it was impossible to accept a license under such terms; but he would point to the success of the company at Newcastle and North and South Shields in contradiction. Another company had accepted the same terms for the whole of London. Although he was prepared to consider any argument raised, he must tell them that the clauses had been accepted by other companies, and he was willing at the moment to give them the exchange on those terms. It was not his wish to establish Post Office exchanges, and cut out private enterprise; and it would afford him the greatest pleasure to hear that a telephonic exchange had been established in Portsmouth, and that it was doing a thriving business.—Mr. King said they could not but admit the force of some of Mr. Fawcett's arguments, to which he (Mr. King) asked permission to reply by letter.—This was agreed to by the Postmaster-General.—Sir Henry Wolff thanked Mr. Fawcett for his courteous reception, and the deputation withdrew.

## ELECTRO-CHEMISTRY.

### INORGANIC.

BY DR. G. GORE, F.R.S.

(CONTINUED FROM PAGE 318.)

**Electrolysis of Terbromide of Antimony.**—$SbBr_3$. Molecular weight = 360. The electrolytic properties of a solution of this salt are much like those of the chloride. It, however, less readily yields a firm deposit of metal. A second variety of the active substance was obtained from it in the following manner:—Dissolve one part by weight of freshly-made teroxide of antimony in ten parts of aqueous hydrobromic acid of specific gravity about 1·3. Filter the solution and electrolyse it with an anode of antimony and a current from three Smee cells, at a speed of deposition of about 4 grains of metal per square inch of cathode per hour.

The deposits thus obtained were of a lighter colour than those from the chloride, they were also quite dull in aspect, and frequently perforated with holes all over the surface like a sponge. This was caused by numerous bubbles of gas. The deposit is less apt to spontaneously crack than the first variety; it is also much more fragile and less hard. Its specific gravity at 60°F. is also much less, and varies from 5·415 to 5·472. It contains a less percentage, viz., 79·52, of metallic antimony. The residue consists of a colourless soft substance composed of terbromide of the metal, and a little hydrobromic acid and water.

It exhibited the same kind of thermic action as the first kind, but the change did not spread throughout the mass unless the substance was previously heated to about 250°F. By contact with a red-hot wire it then evolved all its heat instantly with explosive violence, and with fracture and dispersion of the substance. By gradually heating the entire substance to about 320°F. it exploded suddenly.

In two pairs of experiments made to ascertain the electro-chemical equivalent of this deposit I obtained 50·09 and 50·11, also 51·2 and 51·4 parts for every 42·5 parts of the active chloride variety deposited, or 32·2 parts of zinc consumed in the same circuit. Each of the quantities of the two kinds of deposit contained about the same, viz., 40 parts, or $\frac{1}{3}$rd of an atomic weight of metallic antimony, the remainder being the associated salt of the metal. These results indicate that in each case the metal alone is deposited by the current, and that during the act of deposition it occludes the saline matter, and acquires the peculiar property.

**Electrolysis of Teriodide of Antimony.**—$SbI_3$. Molecular weight = 503. The solution employed was prepared as follows:—Dissolve one part by weight of recently precipitated teroxide of antimony in fifteen parts of aqueous hydriodic acid of specific gravity 1·25. A current sufficiently strong was passed through it, by means of an anode of antimony, to deposit the metal at a rate not exceeding one grain weight per square inch of cathode per hour. During the process the tendency to evolution of hydrogen was so great as frequently to completely disintegrate the deposit.

The substance thus obtained was dull in appearance, grey in colour, scaly, extremely fragile, soft, and much less metallic than even that obtained in the bromide solution. Its specific gravity was 5·27. On immersing it in water bubbles of gas issued from all parts of its surface during a few seconds, and produced a hissing sound like that of slaking lime. Pieces one-ninth of an inch in thickness required to be heated to 338° F. before the contact of a red hot wire would cause them to discharge their heat; they then discharged feebly and evolved red vapours of antimonic iodide.

The unchanged substance yielded on analysis 77·76 per cent. of metal, the remainder being solid red iodide of antimony and a little aqueous hydriodic acid. By depositing it slowly, *i.e.*, at the rate of ·5 grain per square inch of cathode per hour, in the same circuit as the chloride variety, its electro-chemical equivalent was determined, and 48·07 parts were obtained for every 42·5 parts of the other kind. The deficiency of equivalent of metal consisted, no doubt, of deposited hydrogen.

For a more complete account of the several varieties of electro-deposited antimony from the three salts see *Phil. Trans. Roy. Soc.*, 1857, 1858, and 1862; also *Chem. News*, Vol. VIII., pp. 257 and 281; and *Jour. Chem. Soc.*

**Electrolysis of Tersulphide of Antimony.**—$SbS_3$. Molecular weight = 218. This compound when in a fused state is readily decomposed, and the antimony separated by charcoal, and various metals, *e.g.*, potassium, sodium, copper, tin, iron, &c.

**Electrolysis of Chlorides of Arsenic and Antimony.**—In the electrolysis of the chlorides of arsenic and antimony some arsenide and antimonide of hydrogen are produced at the cathode. If the three metals—arsenic, antimony, and tin—are simultaneously present, they are deposited in the order given. From the solutions of the sulphides of those metals in alkaline sulphides tin and antimony are deposited completely, and arsenic not quite completely, in the metallic state (C. Luckow, *Jour. Chem. Soc.*, Vol. XXXVIII., 1880, p. 283).

**Electrolysis of Antimoniate of Potassium.**—Bartoli and Papasogli electrolysed an aqueous solution of this salt by means of a current from eight Bunsen cells and an anode of wood charcoal or gas carbon. Very much gas was evolved at the cathode, and a small amount at the anode. The anode was strongly attacked, and the electrolyte became deep black. The authors found in the electrolyte a compound of carbon, hydrogen, oxygen, and antimony, which they term stibiomellogen (*Jour. Chem. Soc.*, Vol. XLII., 1882, p. 406).

For the electro-chemical analysis of antimony compounds see *Jour. Chem. Soc.*, Vol. XLII., 1882, p. 1,320; *Chem. News*, Vol. XLVI., p. 106.

**Separation of Bismuth.**—Bi. Atomic weight = 210. A triad cation. Much less easily deposited in a coherent state than antimony. By simple immersion tin coats itself with very small shining plates of bismuth in a solution of ten grains of nitrate of bismuth and a wine glass full of distilled water, to which two drops of nitric acid have been added. Commaille (*Chem. News*, Vol. XIV., p. 188) states that magnesium deposits bismuth from solutions of its salts by simple immersion. I have observed that it is also deposited from its aqueous chloride by zinc, tin, lead and iron, but not by bismuth, antimony, copper, brass, German silver, gold, or platinum.

**Electrolysis of Oxide of Bismuth.**—Burckhard states that fused oxide of bismuth is easily decomposed by a current from 12 Bunsen cells with electrodes of copper; if platinum wires are used, an easily fusible alloy of the two metals is formed (*Zeitschrift fur Chemie*, Vol. VI., p. 212). Melted oxide of bismuth is instantly reduced to metal by contact with antimony (H. Tamm, *Chem. News*, Vol. XXV., p. 85-100).

**Formation of Peroxide of Bismuth.**—Wernicke has prepared this compound as a black deposit, having the composition represented by $BiO_2, H_2O$, and a specific gravity of 5·571, by electrolysing by a current from two Daniell cells, with an anode and cathode of sheet platinum, a solution of a mixture of basic nitrate of bismuth and tartrate of sodium. (*Pogg. Annalen*, Vol. CXLI., p. 109.)

**Electrolysis of Nitrate of Bismuth.**—Sodium amalgam decomposes a saturated solution of nitrate of bismuth, setting free hydrogen and black powder of bismuth (Böttger). By the separate current process an anode of the metal, an extremely feeble current, and a solution of the nitrate in water, with the minimum amount of free acid to render it clear, I have deposited the metal as a very beautiful but thin coating, white, with a faintly pinkish tint, and a fine silky lustre. According to some writers such a deposit is explosive.

**Electrolysis of Fluoride of Bismuth.**—With pure dilute hydrofluoric acid, a bismuth anode, and a current from a single Smee element, the conduction was extremely feeble, and only a black film was deposited upon a copper cathode in thirty hours.

**Electrolysis of Chloride and Iodide of Bismuth.**—Metallic bismuth may be deposited upon copper or brass, by means of a current from a single Bunsen cell, from a solution composed of 25 to 30 grammes of the double chloride of bismuth and ammonium, dissolved in a litre of water, faintly acidified with hydrochloric acid. The deposit consists of a blackish

Digitized by Google

mud, with a film of bright adherent bismuth beneath. (Bertrand, *Athenæum*, April 22, 1876, p. 570; also *Jour. Chem. Soc.*, Vol. I., 1876, p. 451.) I have deposited the metal, evidently containing some ingredients of the liquid, by a separate current and a bismuth anode, from a solution of iodide of bismuth and iodide of potassium. The deposit was an extremely bulky, jet black powder, which contained iodine even after most persistent washing, and became slowly oxidised by exposure to the atmosphere.

A cyanide solution has also been recommended for depositing bismuth, but an anode of that metal does not readily dissolve in a hot solution of potassic cyanide.

One part of bismuth in 1,200,000 parts of mercury may be detected by the addition of potassium amalgam and water, the bismuth being electrolytically separated as a black powder on the sides of the vessel (*Scrullas. Ann. Chem. et Phys.*, 3rd Series, Vol. XXXIV., p. 192).

For the electrolytic analysis of compounds of bismuth see V. Francken, *Chem. News*, Vol. XLVI., p. 106; also *Jour. Chem. Soc.*, Vol. XLII., 1882, pp. 896 and 1,320.

**Separation of Osmium.**—Os. Atomic weight = 199. A cation. Zinc deposits osmium in the form of black flocks when immersed in a solution of the black oxide in concentrated hydrochloric acid. Metallic mercury decomposes a solution of osmic acid, and forms an amalgam of osmium and mercury (Tennant).

Smee electrolysed a solution of osmic acid ($OsO_4$), and obtained a black deposit. Wöhler passed a current from two Bunsen cells by means of an anode of osmium through dilute sulphuric acid; the metal was freely converted into osmic acid; also through a solution of caustic soda, the latter became of a deep yellow colour, and a deposit of osmium was formed upon the cathode (*Chem. News*, Vol. XIX., p. 10).

**Ruthenium.**—Ru. Atomic weight = 104·2. A cation. No reliable electrolytic experiments appear to have been made with this metal. Its great rarity and infusibility, extreme cost, and porous structure, are the chief obstacles.

**Separation of Rhodium.**—Ro. Atomic weight = 104·3. A cation. Smee stated that by means of a separate current from ten of his cells, and platinum electrodes, he deposited this metal from a solution of its sodio-chloride, and obtained a brittle white deposit; and that with a stronger current the deposit was a black powder.

**Separation of Iridium.**—Ir. Atomic weight = 197. A cation. Sodium amalgam decomposes a concentrated solution of sodio-iridium chloride, and forms an amalgam of iridium. According to F. Wöhler, osmi-iridium is readily dissolved as an anode in a solution of caustic soda. Smee stated that he had deposited this metal in a bright reguline state on a small scale. According to a writer in *Dingler's Polytechnick Journal*, both electro-deposited iridium and rhodium detonate when heated (*Jour. Chem. Soc.*, 2nd Series, Vol. XI., p. 1,007) probably in consequence of their containing hydrogen.

**Separation of Palladium.**—Pd. Atomic weight = 106·5. A cation. Mercury decomposes a solution of a palladium salt, and forms an amalgam. According to S. Kern (*Chem. News*, Vol. XXXIII., p. 236), the immersion of magnesium in aqueous solutions of salts of palladium yields hydrogen, monoxide of palladium, and hydrogenated palladium.

**Formation of Peroxide of Palladium.**—$PdO_2$. Molecular weight = 158·5. An anode of palladium, used to conduct a current from two Bunsen elements into dilute sulphuric acid, became slowly covered with an almost insoluble film of this compound (F. Wöhler, *Chem. News*, Vol. XIX., p. 10).

I passed a current from fifty Smee elements, by means of a palladium anode and platinum cathode, through dilute sulphuric acid. No odour of ozone occurred at the anode, unless the latter dipped but a very small depth into the liquid. Conduction was copious, and a deposit of splendid colour—red, purple, &c.—formed upon the anode. By reversing the direction of the current, the now well-known phenomenon of bending of the cathode by absorption of hydrogen took place; and by removing the charged cathode from the liquid and bending it by mechanical means it evolved heat.

(TO BE CONTINUED.)

## SOME ELECTRIC AND MAGNETIC PROBLEMS.

BY W. M. MOORSOM.

### Action of a Straight Current upon a Magnet Pole of Strength $m$.

Let the current A B be of infinite length in a straight line. Suppose it to revolve around the magnet pole P. Then, since its length is infinite, it will in its revolution cut all the lines of magnetic induction emanating from P.

$\therefore$ in each revolution $N = 4\pi m$.

$\therefore$ work done $= 4\pi m C$, C being the current.

But work done $= F\,2\pi r$, where F is the mutual pressure between the current and the pole, and $r$ is the radius of the cylinder described by the current.

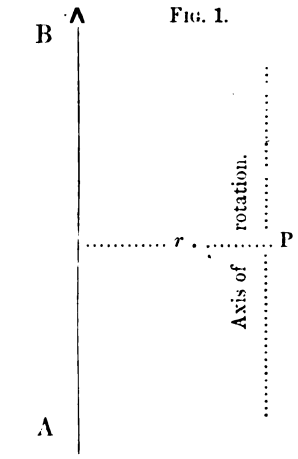

Fig. 1.

Hence $F\,2\pi r = 4\pi m C$.

$$\therefore \quad F = m\frac{2C}{r}.$$

### Action of a Circular Loop upon a Magnet Pole at the Centre.

Consider the half loop K C H (Fig. 2).

Let it revolve round an axis K P H, then it will cut all P's lines of induction in each revolution, and, as in Case I.,

Work done $= 4\pi m C$.

But work done $= F\,2\pi x$, where $x$ is the radius of the mean path described by the half loop.

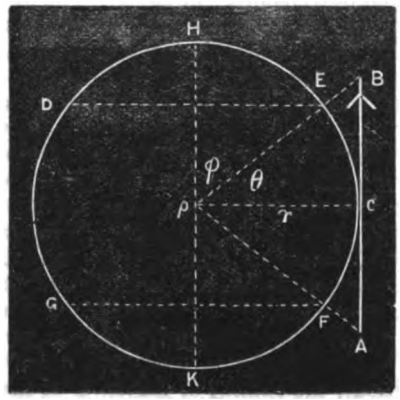

Fig. 2.

By Guldenic's principle, $2\pi x \times$ length of curve K C H = surface of sphere,

or $2\pi x \times \pi r = 4\pi r^2$.

$$\therefore 2\pi x = 4r$$

whence $F\,4r = 4\pi m C$.

$$\therefore \quad F = \pi m\frac{C}{r},$$

and $$2F = \pi m\frac{2C}{r}$$

= mutual pressure between the circular loop and the pole.

Digitized by Google

It is evident from the method pursued that both this formula and the preceding one refer to the same current.

### Action of a Finite Straight Current upon a Magnet Pole.

Let A B be a sliding conductor, carrying a current, and capable of revolving around the axis K P H. Then in each revolution the lines of induction cut by the slider are those which fall upon the surface of the zone D E F G, and these lines bear the same proportion to the whole number emanating from P as the surface D E F G bears to the whole surface of the sphere.

But the surface D E F G

$$= \text{surface of sphere} - \text{the two caps D E H, F G K}$$
$$= 4\pi r^2 - 2 \times 2\pi r^2 (1 - \cos\phi)$$
$$= 4\pi r^2 \cos\phi = 4\pi r^2 \sin\theta$$
$$\therefore \frac{N}{4\pi m} = \frac{4\pi r^2 \sin\theta}{4\pi r^2}.$$

Whence $N = 4\pi m \sin\theta.$

$\therefore$ work done $= 4\pi m C \sin\theta$

$$= F\, 2\pi r$$
$$\therefore F = m\frac{2C}{r}\sin\theta.$$

I do not find this formula in the text books, and shall be glad if some of your readers will say whether it is correct or not. I have found it agree well with a few experiments which I have been able to make to test it. The objection to it is fundamental, namely, that as all our experiments are made with closed circuits, we have no data from which to reason about portions of circuits taken separately. But, on the other hand, if one portion only of a closed circuit be movable, and if we know that when that portion is moved a definite distance ($d$), there results a definite increase (E) of energy in the closed circuit, may we not conclude with truth that the force upon that moving portion $= \frac{E}{d}$? And this is all that is done in the proposition given above.

### "Critical Speed" of Dynamos.

In Professor S. P. Thompson's admirably lucid description and explanation of dynamos,* he says, "The discovery of the method of rendering a dynamo machine automatically self-adjusting, so that either its electromotive force or its current (according to circumstances) shall be constant, is due to M. Marcel Deprez, who has shown mathematically that if a dynamo be wound with a double set of coils, one of which can be traversed by an independent current, whilst the other set is traversed by the current of the machine itself, there can always be found a certain critical velocity of driving, for which, provided that the field magnets are far from attaining their saturation point, the desired condition is fulfilled."

Professor Thompson describes the arrangement requisite, but he does not give the mathematical proof; and as others, like myself, may be out of the way of seeing M. Deprez's paper on this subject, I submit the following, as a proof that, under certain conditions, the E.M.F. of the outer or main circuit will be constant, even while the resistances in the current are continually changing.

Suppose a coil of one turn, whose area is A, placed in a magnetic field whose mean intensity per square centimetre is H (Fig. 3).

Let the coil or loop be turned on an axis through O, from the dotted position D E, in which no lines of magnetic induction pass through it, into the position A B C, at right angles to the first position.

Then the number of lines cut by the loop in this quarter-revolution is the whole number which pass through it in position A B C. And this number is H A.

$\therefore$ work done in one complete revolution $= 4$ H A C, where C is the resulting current.

* Cantor Lectures, Dec., 1882.

Let $n$ be the number of revolutions the loop makes per second.

Then work per second $= 4$ H A C $n$.

Also work per second $=$ E C,

whence E $= 4$ H A $n$ = total E.M.F.

But as the field magnets are excited partly by the main current C, and partly by an independent source,

$\therefore$ H $= H_1 + kC$, where $H_1$ and $k$ are constants.

$\therefore$ E $= 4 H_1 A n + 4 A n k C$.

But E always $=$ R C $+$ E$^1$, where R $=$ all the resistances except those of the external circuit or main.

E$^1$ $=$ the E.M.F. of the external circuit, hence

$$R C + E^1 = 4 A n k C + 4 H_1 A n.$$

Now drive the loop (or dynamo) so fast that $4 A n k = R$, then E$^1 = 4 H_1 A n$, a constant so long as the speed is not changed.

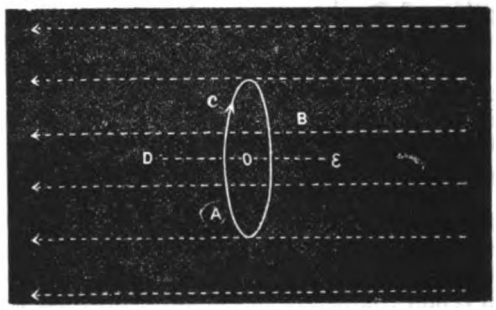

Fig. 3.—The axis of rotation through O is at right angles to the paper.

Also it is evident that any required constant E.M.F. can be obtained in the external circuit by suitably varying the strength of $H_1$, that is, of the current which comes to the field-magnets from the independent source.

### The Ballistic Galvanometer.

Let Q be the quantity discharged from a condenser through the galvanometer,

Let the position F O B in Fig. 4 represent the extent of the first swing of the needle,

Let K be the capacity of the condenser,

H the horizontal component of the earth's magnetic field,

$m$ the strength of needle poles,

L length of needle.

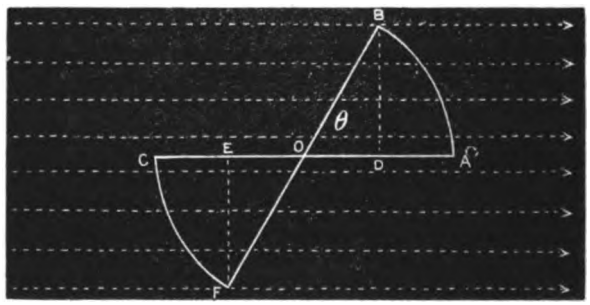

Fig. 4.

Draw B D, F E, at right angles to A K.

Then the total energy of discharge $= \frac{Q^2}{2K}$,

and the work done by the discharge upon the needle will, other things being equal, be a definite proportion $\left(\text{say } \frac{1}{n}\text{th}\right)$ of the total energy.

$\therefore$ work done by discharge upon needle $= \frac{Q^2}{2nK}$,

and this is equal to the work done by the needle against H in

Digitized by Google

swinging through angle $\theta$—that is, to $m$ (H . A D + H . K E) = $m$ H . 2 A D.

$$\therefore \frac{Q^2}{2nK} = F m H . A D = m H L (1 - \cos \theta)$$

$$= F m H L \sin^2 \frac{\theta}{2};$$

whence $$Q = F \sqrt{m n H L K} \sin \frac{\theta}{2},$$

or quantity discharged varies as the sine of half the angle of the first swing.

## ON MECHANICAL DYNAMOMETERS.

BY GISBERT KAPP.

(CONTINUED FROM PAGE 226.)

A modern and very perfect form of rotary transmission dynamometer,* used by the Royal Agricultural Society, is shown in Figs. 19 and 20, the former being a transverse section, and the latter a longitudinal section.

The power from the prime mover is led into the dynamometer either by the coupling E or by a belt driving on pulley A, which is keyed to the shaft; and it is conveyed to the machine under test by a belt from pulley B. This pulley is loose on the shaft, but connected to A by two or more pairs of flat spiral springs, the two springs forming one pair being coiled in opposite directions, so that the tendency of the springs to uncoil or straighten themselves in consequence of centrifugal force cannot produce rotation of the pulley.

The inner ends of these springs are fastened to the boss of pulley B, which, for this purpose, is somewhat prolonged into A, and the outer ends are fastened on the inside of the rim of A, the pair H, which lies within that pulley, being fastened direct, and the pair G by means of transverse pieces F, as shown in the small sketch by the side of Fig. 20.

To the boss of the driving pulley B is fastened a hollow cylinder K, the outer edge of which is cut to a double quick threaded screw, and against this edge rests a crossbar, passing through a slot in the shaft and kept up by a spring. To the centre of this crosspiece is attached a light spindle, passing through a central hole in the end of the shaft, and connected to a fork, which embraces the integrating wheel P. If there is no twisting movement between the two pulleys, the double thread of the screw K is symmetrical to the slot in the shaft, and the crosspiece is in its inmost position, at the same time bringing the integrating wheel into the centre of its disc, that is, to zero. If, now, in consequence of a strain transmitted, the driving pulley B lags behind the driven pulley A, the slot in the shaft will have been turned relatively to the screw K, thus pushing the crosspiece a certain distance out from its inmost position, this distance being, of course, proportional to the twisting movement between the two pulleys. In this manner is obtained exact proportionality between the displacement of the integrating wheel and the strain transmitted. The integrating disc is revolved by gearing driven from the small spur wheel shown on the spindle where it protrudes from the shaft. The apparatus just described is also provided with a paper cylinder, driven by similar gearing at a speed proportional to that of the shaft, and a pencil attached to the rear of the fork is used to draw a diagram of the energy transmitted on the paper. In this way the dynamometer is not only an integrating, but also a recording instrument.

A transmission dynamometer, depending on the use of cylindrical spiral springs, which elongate when transmitting power, has been invented by Messrs. Ayrton and Perry, and was brought before the Society of Telegraph Engineers and of Electricians in September, 1882. Two forms of this instrument are shown in Figs. 21 and 22, for the engravings of which the author is indebted to the inventors.

The paper mentioned describes the invention so clearly that it will be best to quote the passage verbatim :—

"The instrument, as seen in the figure, consists of a pulley E, rigidly fixed to the shaft C D, a loose pulley G, and a pulley H, joined by the spiral springs B to the ribbed plate E, which is rigidly fixed to the shaft C D. If, then, the engine belt is on F, and the belt to the dynamo or driven machine on H, or *vice versâ*, the springs B will be stretched, depending on the "torque" or twist transmitted. The extension of these springs causes, by means of a small link-motion seen at the lower right hand corner of the figure, the bright bead A, at the end of a long arm, to approach the centre. Hence the smaller the radius of the circle described by this bright bead as it revolves the greater the torque. Consequently, the horse-power transmitted is at once obtained from observing the indicated torque and the speed of rotation. The arm carrying the bead is slightly flexible, and when no power is being transmitted the bead is pressed with a certain force against the rim of the front plate. Hence the bead does not commence moving until a certain pre-arranged horse-power, at a given speed, is being transmitted. Its whole radial motion, therefore, is completed for a certain additional transmitted horse-power, the necessary addition depending on the power of the springs and the leverage of the link-motion. Consequently, a large change in the radius of the circle of light is produced by a small change in the transmitted horse-power. Further, one of the pins in the links can be taken out and put into another hole, which has the effect of greatly altering the leverage of the links, thus increasing the magnification, and causing the motion of the bead to be completed for another range of power. For example, the springs and link-motion may be so arranged that, with one of the two adjustments, the bead may commence to move when 8 horse-power is being transmitted at a certain speed. The whole motion from the circumference to the centre may be completed when the horse-power transmitted varies from 8 to 12.

"With the other adjustment the bead may start moving when

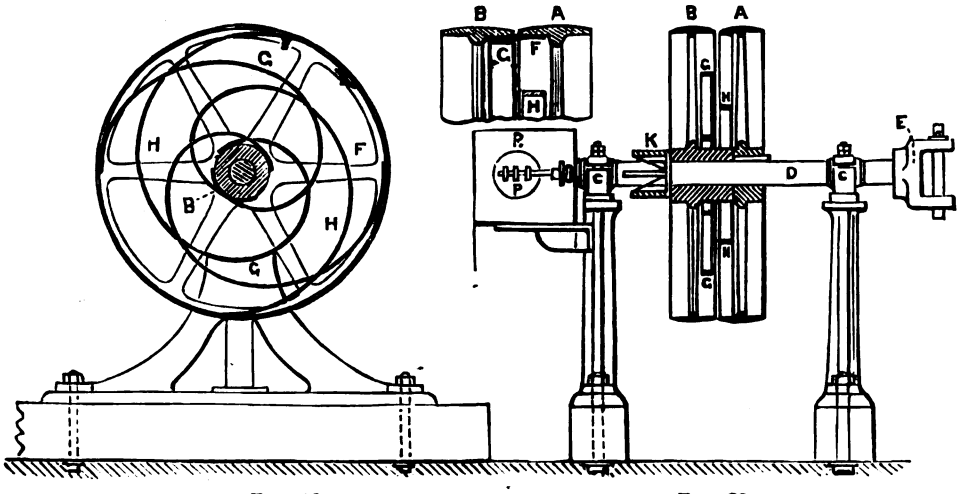

FIG. 19.

FIG. 20.

* See Mr. Rich's paper in *Proceedings* Institution of Mechanical Engineers, February, 1876.

Digitized by Google

4 horse-power is being transmitted, and the entire travel of the bead from the circumference to the centre completed by this transmitted horse-power increasing from 4 to 6. Slipping either the driving or driven belt on to the loose pulley G causes the transmission dynamometer and the dynamo machine to stop while the engine is going on.

"The next figure shows our dynamometer-coupling, which differs only from the preceding in that it is intended to be used with machinery driven directly by shafting where belting is not employed. For instance, this coupling may be used to measure the horse-power given by a fast-speed engine to a dynamo driven directly by it, or it may be employed to measure the power given by a marine engine to the screw or to the paddles, or generally the horse-power transmitted along any line of shafting, the spring-coupling, in fact, replacing the ordinary coupling used with such shafts.

"One of the halves of the coupling seen in the figure is keyed to the driving shaft—for example, the shaft of a fast-speed engine—and the other to a driven shaft—for example, that of the dynamo. The half C is attached to the other half by means of the spiral springs, and the stretching of these is therefore a measure of the torque. The angular motion of the one relatively to the other causes the bright bead B to approach the centre, and, as before, the radius of the circle of light measures the horse-power transmitted at any particular speed. The arm E, carrying the bead, is also, as before, slightly flexible, so that when no power is being transmitted, the bead B is pressed with a certain force against the rim of the larger plate. Hence the bead does not commence to move until a certain pre-arranged horse-power, at a given speed, is being transmitted, and the whole motion is completed for any pre-arranged excess beyond this, thus enabling delicate measurements to be made at powers a little more or less than that normally transmitted.

"By a proper arrangement of the link motions, we have succeeded in making the radial motion of the bead in both instruments exactly proportional to the extension of the spring or twist transmitted.

"The transmission dynamometer and dynamometer-coupling just described have the great advantage over any sort of laboratory dynamometers, in that the former have not to be put into position and adjusted for each particular experiment, but are always ready, and are always indicating the power transmitted at any given speed. If, for example, a dynamometer-coupling be inserted in the shafting of a factory in place of the ordinary coupling, a glance at it at any time will show the power that is being transmitted by it. If two such dynamometer couplings be inserted at two places in the same set of shafting, the difference between the transmitted powers indicated by them is the power utilised by the machinery driven by that portion of the shafting that is between them."

Any shaft, whilst transmitting a rotary strain, is twisted to a certain extent. The fibres of the metal, which, when the shaft is in an unstrained state, can be imagined as being parallel to its axis, are deflected into screw threads, the pitch of which is inversely proportional to the torque transmitted.

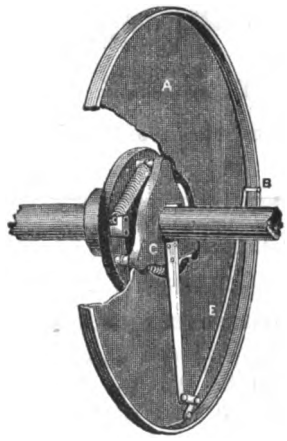

FIG. 22.—Ayrton and Perry's Dynamometer Coupling.

Upon this is based the dynamometer of Mr. G. A. Hirn. It consists essentially of a piece of shaft, to one end of which is keyed the wheel receiving the power, and to the other end the wheel transmitting the power to the machine under test. The angular displacement of one wheel to the other is magnified by gearing, and made visible on an external index lever.

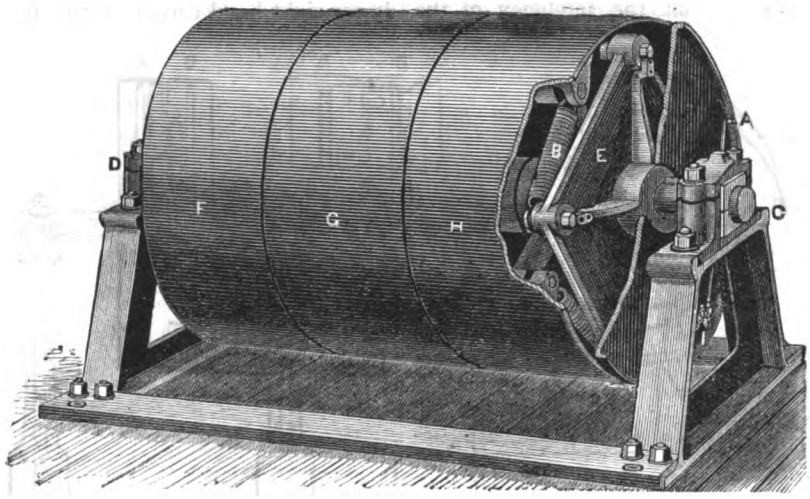

FIG. 21.—Ayrton and Perry's Transmission Dynamometer.

M. Bourdon's dynamometer, intended for the measurement of large powers, is based upon the principle that in helicoidal gearing the thrust exerted upon the driven wheel in a direction parallel to the axis is proportional to the pressure beween the teeth, and therefore to the strain transmitted.

To make this clear, imagine a pair of spur wheels, the teeth of which are not quite parallel to the line of shafts, but slightly inclined to it, each tooth being, so to speak, part of a screw thread of very large pitch. The natural tendency of the driven wheel must be to slip away from its work—that is, to be forced back in a direction parallel to its shaft, and if this end thrust were not taken up by some counteracting force, the wheels would eventually come out of gear.

The amount of end thrust depends on the pressure between the teeth, and on their inclination towards the line of shafts. If the angle be very small, the force necessary to balance the thrust will be small, and a comparatively light spring applied to the end of the shaft of the driven wheel suffices to keep the wheels in gear even when transmitting a very heavy load. In M. Bourdon's dynamometer the face of the driving wheel is made sufficiently wide to allow a considerable displacement of the driven wheel, the amount of this displacement and resulting compression of the spring being proportional to strain transmitted.

## DIRECT-READING ELECTRIC MEASURING INSTRUMENTS.*

BY PROFESSORS W. E. AYRTON, F.R.S., AND JOHN PERRY, M.E.

The construction and use of our various measuring instruments are now sufficiently well known that it is unnecessary for us to give any general description of them; indeed, the names "Ammeter," "Voltmeter," by which we ventured to christen two of our children have found favour in the eyes of electricians, and are now current in electrical literature as the typical names, or surnames, of instruments used to measure strong currents and large electromotive forces respectively. But just as improvements in electrical measurements have led, step by step, to the names for the electrical units receiving more and more exact definitions, so we now propose to take advantage of certain important improvements that we have recently effected in our measuring instruments to define the names "Ammeter," "Voltmeter" and "Ohmmeter" more exactly.

*Proportional Law.*—In the earliest form of instruments commercially employed for measuring the large currents used for electric lighting, viz., the instruments of M. Deprez, reference had to be made to a table of values to ascertain the meaning of any particular deflection, since there was no immediate connection between 1 degree deflection and 1 ampere, and further it was necessary to refer to the table twice over when measuring two different currents, as the deflections were not proportional to the current. By giving a proper shape, however, to the coil, needle, and to the pole pieces of the controlling permanent magnet, we succeeded, in 1880, in producing instruments in which the current or potential difference was exactly proportional to the deflection throughout the whole range of the scale, and further by the employment of our commutator principle an instrument was obtained having two degrees of sensibility, one exactly ten times the other, so that a commutator, ammeter, or voltmeter, although employed to measure strong electric currents and large potential differences, could be calibrated by the employment of a single cell of known electromotive force but of totally unknown resistance.

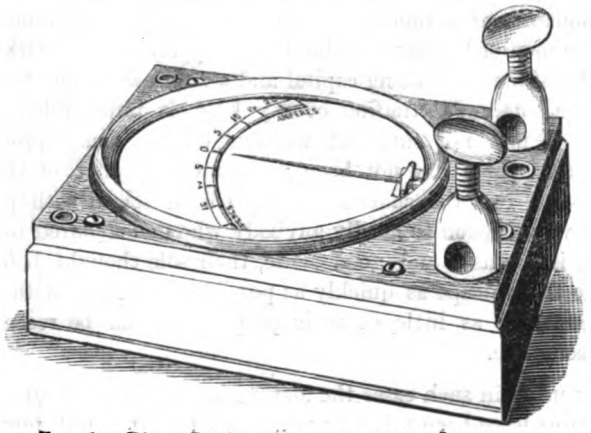

FIG. 1.—Direct-Reading Non-Commutator Instrument.

*Objections to the Employment of a Constant.*—But these instruments possessed one serious fault, looked at from the user's point of view, and two others, which especially concerned the manufacturer. The scales of all the instruments were divided into degrees, and although the deflections were proportional respectively to the current, or the potential difference to be measured, still there was nothing to show to how many amperes or volts one degree of the scale corresponded. Consequently for each instrument there was a "calibration constant," such as 1·75 amperes or 2·14 volts per degree, which was determined experimentally by the makers. We have here two of such old type of voltmeter, in one of which 5·7 volts produces one degree deflection, and in the other 0·09 volt produces one degree, the former being intended for measuring electromotive forces of about 230 volts, the other the electromotive force of a single cell. But the employment of such a constant had the very serious objection that, as all the instruments looked exactly alike, there was the great danger in any factory, where several of these instruments were in use, of the constant for one instrument being used accidentally for that of another. And this mistake not only rendered the answer, of course, quite wrong, but was liable to lead to the destruction of the instrument, or, at any rate, to the breaking of the pointer, from, say, an instrument having a constant 0·12 ampere per degree being put on a circuit through which 50 amperes are flowing, in consequence of the experimenter mistaking the constant for 1·2 ampere per degree. Further, even if no mistake be made in the constant it is troublesome, except for those who are expert in mental calculation (a quality not always predominating in the men in charge of electric light circuits), to multiply a constant 3·17 by the deflection, say 21·32, quickly without the employment of paper and pencil.

We therefore decided, not merely to avoid using tables of values, such as had to be employed by M. Deprez, but even to abandon the use of constants altogether, and to arrange matters so that the pointer pointed at once throughout the whole range of the scale to the number of amperes or volts to be measured—to design, in fact, "direct-reading" instruments. And for the future we propose to confine the definition of an "ammeter," a "voltmeter," and an "ohmmeter" to instruments in which respectively amperes, volts, and ohms can be immediately read off without any calculation or any reference to a constant or table of values.

On the table there are various specimens of our new direct-reading ammeters and voltmeters. In each case the dial is a complete disc (*see* Fig. 1), and not a sector as in the old instruments. The light aluminium pointer is also much longer, and the length of the graduated arc over which its end moves is much greater, so that readings with the new instruments can be made much more accurately than in the old. Here is a direct-reading ammeter suitable for measuring up to 10 amperes correct to a tenth of an ampere—here another for measuring up to 150 amperes, each division of the scale corresponding with one ampere. I now send a current with these accumulators through this thick German silver wire and you see at once from the deflection on this other ammeter, without any reference to a table of values, and without the employment of any troublesome constant, that the current passing, and which is now making the wire white hot, is 207 amperes. Again, each division on the scale of this voltmeter corresponds with 1 volt, this particular instrument being suitable for measurements up to 100 volts.

To construct a direct reading instrument it is necessary to employ some form of adjustment for sensibility, since to have a special scale engraved for each instrument after it was wound would be both troublesome and expensive; and further, if there were no power of adjustment any change in the strength of the permanent controlling magnet would prevent the instrument any longer giving one division deflection per ampere or per volt—in other words, would necessitate the employment of a constant.

*Difficulties of Manufacture of Older Forms.*—As regards the two defects, from the manufacturer's point of view they were these. Even although the shape of the coil, needle, and pole pieces of the magnets were made accurately to templates, it was found difficult when very thick wire had to be coiled on the bobbin of an instrument, for measuring strong currents, to wind it with certainty, so that both the deflection was proportional to the current, and so that equal deflections on the two sides of the zero had exactly the same value. As long as the wire was thin symmetry of winding was comparatively easy to obtain, but when thick wires, having but a few convolutions, were wound round a small bobbin, the thickness of the wire combined with the galvanometric importance of each of the few convolutions, especially of those closest to the needle, made it necessary to wind and rewind some of the instruments several times before the proportional law, as well as equal deflections right and left, could be obtained.

*Adjustment of "Direct-Reading" Instruments.*—It therefore was important, to avoid complexity of construction, that the adjustment for sensibility referred to above should, if possible, be so contrived as to serve also for an adjustment for the proportional law. And this we are happy to say we have at last succeeded in accomplishing by fitting into each end of the bobbin round which the wire is wound specially constructed charcoal iron cores fitted with a fine screw. If these cores be too far out, or out altogether, the proportional law will probably not be true, the current increasing more rapidly than the deflection. On the other hand, if they be screwed fully home the proportioned law will also not be true, the deflection now increasing more rapidly than the current; but we find that between two limiting positions of these iron cores the proportional law is true, and by moving the cores in or out within these limits the sensibility of the instrument can be much altered without destroying the proportional law.

To construct then, say, a 50 ampere instrument wire is selected of such thickness, first, that 50 amperes will not heat it too much; secondly, that a sufficient number of convolutions can be wound on the bobbin for 50 amperes to deflect the needle to the limit of the scale when it is controlled by a permanent magnet of normal power. A scale divided for 50 amperes, that is, having the division marked 50 amperes at the end of its range, is then put on, and the soft iron cores screwed in or out a little by trial until the pointer points to exactly the same number on the dial as the number of amperes of current flowing through the coil. If at any future time it be found that the permanent magnet has lost some of its magnetism, so that less than, say, 40 amperes will deflect the pointer to the 40 ampere mark on the dial, the iron cores are unscrewed out a very small distance until the change in the magnetism of the controlling magnet is exactly compensated for.

The other adjustment to be employed by the makers for equalising the deflections right and left for the same current is effected by fixing the coil so that it can turn about its centre.

The "Ten Law" of our commutator instruments, which means that an ammeter is exactly ten times as sensitive when the commutator is turned to series as when to parallel, while a voltmeter is ten times as sensitive when the commutator is turned to parallel as when turned to series, is effected by the ten wires forming the bobbin, having, inclusive of the resistance of the contacts at their ends, exactly the same resistance, which condition being fulfilled it is quite unnecessary for obtaining the ten law that the ten wires composing the strand should be at all symmetrical in the way in which they are wound on the bobbin. With some of our earlier commutator instruments the resistance of the contact of the springs with the metallic pieces of the commutator introduced an error when the ten wires were each thick and short, since then the terminal resistance was a very material portion of the whole resistance of any one of the ten wires. To avoid this the commutators and the springs, as will be seen from the various specimens of the instruments on the table, which, Darwinian like, show the history of the survival of the fittest, have assumed a much larger form.

(TO BE CONTINUED.)

## THE METROPOLITAN BRUSH ELECTRIC LIGHT COMPANY.

Last week we had to notice the decisive and enterprising conduct of a Company who were in financial difficulties, but determined to get out of them and start afresh. This week conduct of quite another kind under identical—or almost identical—circumstances demands our attention in respect to the Metropolitan Brush Electric Light Company. The parent Corporation boldly effaced one-half of its nominal capital, and are at work with the real remaining half; the child company, on the contrary, has decided to efface itself altogether, hoping, perhaps, to save the residue of its capital from being similarly wiped out. One gentleman, indeed suggested "for the consideration" of last week's extraordinary general meeting that their capital be reduced from £500,000 to £200,000; but his audience were in no humour for considering anything, and the proposition was scouted as one of those red-herrings, several of which—according to their view—were drawn across the headlong course of the shareholders. From what transpired during the proceedings it certainly did not seem worth while to reduce it by even that vast sum, when in reality the value of the assets would be more nearly represented by the proposer's round number, minus one of its ciphers. Mention was made of £280,000 having been lost; but it is only fair to remember that it has not been lost in the trade of electric lighting; it has probably gone into the pockets of the people who sold the concession. What has been lost, if anything, in legitimate business was not stated at the meeting. The assembled shareholders, in short, seemed to be smarting under the impression that they had paid a vast sum of money for a privilege of which they could make nothing at all.

In considering the action of the shareholders, which, if confirmed by the next following meeting, will result in the winding up of the whole concern, the fact should be borne in mind that reasonable time has not been allowed to test the business of electric lighting as a commercial affair, much less to develop it. It is too late to point out that capital expended on concessions meant so much less capital invested in manufacture; but to men of business it should be apparent that, without a good residue of working capital and a reasonable time to work with it, successful trading of any kind is impossible. That there is now not sufficient working capital seems probable, and that there has not been sufficient allowance of time is obvious. But the shareholders had been seized with panic; they would listen to hardly anybody who endeavoured to calm them into reason and good sense, their sole thought being to make their escape as quickly as possible, and carry with them as much, or as little, of their property as can be rescued in the scramble.

As usual in such cases the alarm is a false one—at all events no pains have been taken to make sure that it is well founded. There is absolutely no evidence that the Metropolitan Company would fail to be a paying concern if it were allowed to carry on its business; whilst there is evidence of a somewhat positive sort that the particular business about which the panic has arisen might have proved remunerative. It is a significant and a most painful circumstance, in more than relates to this particular Company, that the shareholders refused to listen to an expert's opinion on the question of whether or not the Company's engineer had under-estimated the cost of the installation for Holborn. The chairman assured the meeting that Mr. Crompton had gone through the estimate, and so far from Mr. Ward's figures being below probable cost, he was of opinion that they were unnecessarily high. In other words, the report of the Committee appointed by the shareholders to investigate this very question was mistaken in predicting the cost of the installation would be so much greater than Mr. Ward's estimate that the supply of light to the Holborn district would involve the company in a serious annual loss. The Committee, judging by the names placed upon it, were, we venture to say, incompetent to form an opinion upon this point; Mr. Crompton was competent to inform them, but was refused a hearing on the technical ground of his not being a shareholder. In ordinary circumstances this disqualification ought to have been his recommendation; but things had reached a stage at which the shareholders would listen only to their own fears. They did not want to be reassured, simply because they were afraid to alter their present

Digitized by Google

attitude towards electric lighting enterprise and all the leading men connected with it.

One other alternative was put before the meeting—thrown at it, somebody said; but it was rejected like all the rest, except the one for winding up. Mr. Hammond made an offer; he would buy the Company at a certain price, chiefly with paper, it is true, but still not at a bad price compared with that which may be realised under liquidation. His mode of supporting this offer, however, only confirmed the meeting in its determination. He called in question Mr. Ward's estimate, and stated that the Holborn installation would not pay; that, in fact, there would be an annual loss of £3,000 upon it. If Mr. Hammond's offer was serious, he overdid the part of depreciator, for he was met by several unpleasant insinuations that he must have a motive for offering to buy such a bad business. The truth is, there is a claim of £200,000 threatened against the original promoters, and the shareholders perhaps hope to recover this sum; but at all events they refuse to sell their right to push the claim, such as it is, for hush-money. It was hinted more than once in the course of the discussion that the gentleman who made this offer was himself one of the promoters against whom the liquidators would, if the Company were wound up, feel it their duty to take proceedings. But this is a matter with which we have no concern; what we desire to point out is that, if Mr. Ward's estimate of the probable amount of business under the provisional order for Holborn is as trustworthy as his estimate for the installation, there is good reason to expect a fair return for the investment; whereas to liquidate and go to law would probably swallow all up in expenses. There is still time to make fuller inquiries as to the probable patronage obtainable in a neighbourhood like Holborn. The Committee's report is not conclusive on this important point.

## THE COUNT DU MONCEL.

It is with deep regret that we have to notice the death of Count du Moncel. At present we can do little more than record the loss sustained by electrical science, and still more by technical literature. The late Count du Moncel was one of the most prolific of writers, and withal as careful and as painstaking as if but one essay at lengthy intervals fell from his pen. Our personal acquaintance with Count du Moncel was of comparatively recent date. We met him for the first time at the International Exhibition at Paris in 1878. Although he was busily occupied at the time, he welcomed the stranger in a manner that will not be forgotten as long as recollection lasts. Several days were given up to our service. The exhibits—scattered as they were throughout the exhibition—were shown and explained to us by one who had evidently made himself thoroughly acquainted with every detail of the apparatus. Since that time the development of electric lighting, telephony, &c., reacting upon electrical literature, and the position of Count du Moncel as editor of *La Lumière Electrique* have tended to unite the bonds of friendship between the writers on both sides of the Channel. The position that *La Lumière Electrique* has taken in the ranks of electrical literature is due in a very great measure to the work of Count du Moncel. He was a member of "The Institute," the author of many books on electrical subjects, anxious to give credit to the real discoverer for his work, a keen experimentalist, deliberate in coming to a conclusion—a man, indeed, whose memory France should delight to honour, as it will be honoured by men of science in every part of the civilised world.

## LEAD PRIMARY BATTERIES FOR ELECTRIC LIGHTING.

BY DESMOND G. FITZ-GERALD.

The facts that lead forms a sulphate which, being wholly insoluble in dilute sulphuric acid, under ordinary conditions effectually protects the metal from further action, and that its chloride also is but very slightly soluble in water at ordinary temperatures, are, perhaps, sufficient to explain why this metal has had such a bad reputation—equally amongst amateur and professional electricians—as a positive element for voltaic batteries. Although sulphuric and hydrochloric acid, sulphates and chlorides, are certainly not the only known electrolytes, and although the iron of commerce—comparatively a bad positive—has occasionally been used to a considerable extent, I can recall only one attempt in this country to utilise lead in the above capacity. And yet this metal offers certain advantages which, even prior to the advent of the dynamo machine, were tolerably obvious. It is true that in the obsolete and misleading "Electro-chemical Series" of Berzelius (which I was sorry to see tacitly endorsed by Dr. Gore,* in his excellent series of articles on "Electro-chemistry," now appearing in this journal) the metal in question appears as electro-negative not only to zinc and iron, but also to cobalt and nickel. It is true also that Professor Guthrie and some other writers make iron electro-positive to lead in the "Contact Series." But Volta placed lead next to zinc in this series, and noticed, moreover, that the difference of potential between them is comparatively small; whilst in 1840 Faraday showed that lead is always electro-positive to iron (*i.e.*, the iron of commerce) in sulphuric, hydrochloric, and nitric acids, and also in alkaline solutions. Recently, Messrs. Ayrton and Perry have found that, whilst the difference of potential between iron and platinum in contact is only ·384 volt, that between lead and platinum is ·766 volt, and that between zinc and platinum is ·976 volt. I may here note that the electromotive force obtained with a lead-platinum couple in dilute nitric acid (4 of the strong acid to 6 of water, by measure) is roughly 1·3 volt; whilst that between zinc and platinum in the same electrolyte is 1·82 volt.

In France it has been proposed to utilise lead, in the ordinary condition of the metal, as the positive element of a couple in which carbon is the negative and dilute nitric acid the electrolyte. Of course, the lead is readily recoverable from the resulting nitrate of the metal; but the recovery, at least in part, of the nitric acid consumed is also a question which is of essential interest from an economic point of view. Now, the reaction between nitric acid (or, more correctly, nitric anhydride, *i.e.* nitric acid *minus* water) and lead in the above cell may be expressed by the equation

$$Pb + 2N_2O_5 = Pb2NO_3 + N_2O_4,\dagger$$

showing that nitrate of lead and peroxide of nitrogen are produced. If this nitrate of lead be decomposed by heat, a second equivalent of peroxide of nitrogen is liberated, thus

$$Pb2NO_3 = PbO + N_2O_4 + O.$$

Finally, the lead may be recovered by the reduction of the oxide according to the equation

$$2PbO + C = 2Pb + CO_2.$$

Since it is known that nitric acid may be regenerated from the peroxide of nitrogen, by means of apparatus such as that patented by Messrs. B. C. Molloy and J. D. Warren in May, 1877, this suggestion is of some practical interest even at the present time. In this apparatus a jet of hot-water spray, in conjunction with a current of air, meets the peroxide as it ascends a shaft or tower, and converts it into nitric acid according to the equation

$$6N_2O_4 + 4H_2O = 8HNO_3 + 2N_2O_2;$$

* p. 103 of the present volume.

† This equation is not strictly correct, since the reaction really involves the production of nitric oxide ($N_2O_2$) and of nitrous anhydride ($N_2O_3$), which become converted into the peroxide ($N_2O_4$) by the action of air.

Digitized by Google

the nitric oxide again becoming peroxide of nitrogen by contact with air.

The great advantage possessed by lead over zinc, from the point of view of the electro-chemist, is that the former metal is easily recoverable from its oxide or salts either by a furnace operation or by electrolysis; whereas the experience of a quarter of a century has pretty conclusively shown not only that zinc cannot economically be recovered by either of these means, but that any attempt to collect and utilise on a large scale the salts of zinc produced in a voltaic cell would be futile. One reason for this is that any commercial demand for zinc sulphate, or for the products obtainable therefrom, can be most economically met by roasting zinc sulphide (Blende or "black Jack"), which is a very abundant mineral. Many years ago, I proposed to utilise sulphate of zinc, obtained by working batteries upon a large scale, by converting it into zinc chloride—Burnett's Disinfecting Fluid—with the simultaneous production of sodic sulphate from common salt; but the demand for the chloride was insufficient to allow of this process becoming commercially successful. If we attempt to recover zinc from its solution by electrolysis, the fact that zinc is electro-positive to hydrogen is evidenced by our obtaining much of this gas and very little of the metal. On the other hand, when we electrolyse an oxide or a salt of lead under proper conditions, the fact that we obtain the metal, with little or no hydrogen, shows that the latter must be electro-positive to lead, although, in the antiquated "Electro-chemical Series" to which I have referred, hydrogen is made electro-negative, not only to lead, but also to copper, mercury, silver, palladium, gold, iridium, rhodium and platinum. I need scarcely point out that all of these metals are reducible by nascent hydrogen, and that the law of electro-deposition is, briefly, that the most electro-negative metal in solution (hydrogen being a metal) *comes down* (or goes up) *first*. But it may save a vast amount of useless endeavour and expenditure on the part of unfortunate inventors to point out, and to reiterate occasionally, that a zinc secondary battery is practically an impossibility, because zinc is on the wrong side of hydrogen in the (true) electro-chemical scale; that a copper secondary battery is practically and theoretically disadvantageous, because copper is *too far* on the right side of hydrogen; and that the peculiar advantages offered by lead as the positive element of a voltaic battery (whether primary or secondary) are due to the fact that it is on the right side of hydrogen and *very close to it* in the electro-chemical scale. It will be useful here to place the following metals in the usual order of their affinities for acid radicals, viz.:—

Zn, Fe, H, Pb, Sn, Cu.

It is of interest also to observe the electro-chemical difference between the element Iron—which, according to this list, should be comparatively a good positive—and the iron of commerce, which, as I have indicated, is decidedly inferior to lead; the electromotive force of "Slater's Iron Cell" (a Bunsen couple in which iron replaces zinc) being but little over one volt. The advantages attending the use of lead as the anode, in charging, of a secondary battery, or in the recovery of lead converted in a primary battery, constitute also an important point, but one which is much more generally understood, and does not require, therefore, to be so much insisted upon.

Perhaps the most important fact in relation to lead primary batteries is that the metal, when in a highly-porous condition—as obtained by the compression of chemically or electrolytically reduced lead—is no longer protected from the action of sulphuric, or of hydrochloric, acid. When employed in this condition as a positive element, it behaves in these electrolytes like amalgamated zinc, with the exception that the sulphate or chloride produced does not enter into solution. This fact, which may be said to have been clearly indicated by the construction of Faure's secondary battery and by the *rationale* of its action, was never directly illustrated in public, so far as I am aware, prior to the lecture on secondary batteries given by Dr. Oliver Lodge at the Society of Arts, May 28, of last year. I had given the lecturer some strips of thin sheet lead coated with the porous compressed metal, but resembling in outward appearance the strips used by the lecturer, to show that an element of lead in its ordinary condition will supply a current only for a very limited period when opposed to a negative element of peroxidised lead in dilute sulphuric acid. The current from the couple formed with the positive of porous lead continued to ring a bell for a period of unexpected duration, and when it at length ceased it was found that the negative instead of the positive element was exhausted. The latter, indeed, would have continued to ring the bell for a very inconveniently protracted space of time.

Lead, then, in a porous condition, can be employed as a positive element, in conjunction with any suitable negative and depolarising agent, with dilute sulphuric acid as the electrolyte; and one at least of the products obtained by the action of this couple, viz., lead sulphate, can be readily recovered, and has, in any case, a considerable commercial value. If the negative element be also lead, in the ordinary condition of the metal, and the depolarising agent peroxide of lead (preferably produced by electrolysis, so as to be in perfect conductive contact with the negative plate of lead), it is evident that all the products of the voltaic action occurring with this couple can be recovered, since sulphate of lead, again, will be produced by the reduction of the peroxide. Calling C the current produced by the battery, E the electromotive force of the latter, R the total resistance in the circuit, $n$ the number of cells, and $e$ the electromotive force of one cell, the weight of lead (Pb) that will give one horse-power of electrical work for one hour will be accurately given by the following equivalent formulæ:—

$$\text{Pb} = \frac{\text{E}.n}{116{\cdot}9\text{R}} = \frac{\text{C}.n}{116{\cdot}9} = \frac{\text{C}.\text{E}}{116{\cdot}9.e} = \frac{746}{116{\cdot}9.e} = \frac{6{\cdot}38\text{ lb.}}{e}$$

If the E.M.F. of each cell be 2 volts, as it would be, roughly, in the couple just specified, the consumption of about 3·2 lb. of metallic lead and of the equivalent weight of lead peroxide (say 3·7 lb.) will give a horse-power electrical for one hour.

Considering now the cost of this horse-power-hour, we have to take into due consideration the immense advantage possessed by lead primary batteries, as compared with those in which zinc is employed as the positive element, viz.: that the residual products of the voltaic action are not only readily collected, but are also *readily reconverted by electrolysis into their original form*. A simple form of electrolytic tank, a suitable electrolyte, a dynamo machine, coal, and some amount of labour, are required for this reconversion. The process, in fact, consists in constructing with the voltaic residues one or more enormous secondary cells (in the form of a tank or tanks); in charging such cell or cells by a dynamo machine, so as to produce at the cathode reduced lead (in a state of fine subdivision), and at the anode lead peroxide in the form best adapted for the purpose in view; and finally in making up elements for primary batteries with the materials so obtained. There is no reason to doubt that this process would be practicable on a large scale, as it has been shown to be on a small scale. Reverting to what, *au bout du compte*, is the main question, what would be the cost of reconverting the quantity of the battery residues which corresponds to the 3·2 lb. of metallic lead and the 3·7 lb. of lead peroxide required to produce one horse-power-hour electrical? The answer to this question is very simple, and, I may venture to state, of very great importance from a practical point of view. This cost will be the cost of one horse-power-hour mechanical, *plus* the cost of the energy transformed into heat by friction in the dynamo and in the passage of the current. Taking as a basis the cost of steam coal in London, the total cost may, I think, be safely set down as *a small fraction over one farthing*. Of course the expenses of *main-d'œuvre*, transport, &c., have to be taken into consideration; but it is certain that no zinc primary battery can compare in point of economy with the best form of battery that can be constructed with elements of lead. When the length of time and the vast expense involved in the establishment of central stations for the general distribution of electric energy are considered, in conjunction with the inconvenience, cost, and economic deficiencies in working of small engines and dynamo machines, it appears probable that a very extended application may be found for lead primary batteries in electric lighting.

## CORRESPONDENCE.

### THE THEORY OF THE GRAMME RING: THE AMPERIAN CURRENT HYPOTHESIS.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: When we compare the direction of two successive currents in a coil by observing the deflection of a galvanometer included in the circuit, it is tolerably obvious that the position of the observer with regard to the coil has no influence on the result. Mr. FitzGerald, however, as far as I can make out, wishes to explain the collapse of his *experimentum crucis* on the ground that he neglected to consider the position of the observer. Under the circumstances it would have been equally pertinent to have noted the height of the barometer. To determine whether any two induced currents will be in the same or in opposite directions it is seldom necessary to consider the position of the observer; that only becomes essential when we have to find the *absolute* direction of the current.

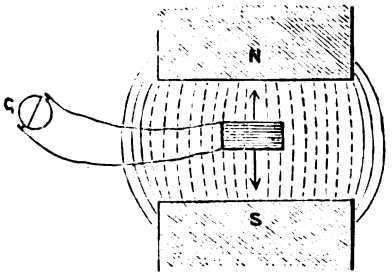
Mr. FitzGerald then proposes to "exhibit the insufficiency and weakness" of the lines of force method by formulating the following statement:—

"When no reversal of position of either magnet, coil, *or observer* (sic) occurs

Adding N lines of force } Current flows in the
„ S „ „ } same direction."

Now, this statement, though perfectly correct, is so "insufficient" as to be utterly misleading when taken by itself. In the absence of a diagram, hardly any one would at once recognise the essential fact that *under the given conditions* it is not possible for both N and S lines of force to be added *to the same face of the coil.*

Is it possible that Mr. FitzGerald has again overlooked the necessity for distinguishing the direction in which the lines of force enter the coil?



The following statement will, I think, prove perfectly sufficient and strong enough to resist Mr. FitzGerald's assault:—

"When lines of force pass through a coil always in the same direction,

| | | | | | | | |
|---|---|---|---|---|---|---|---|
| Adding | N | lines | current | flows | in | positive | direction |
| „ | S | „ | „ | „ | „ | negative | „ |
| Subtracting | N | „ | „ | „ | „ | „ | „ |
| „ | S | „ | „ | „ | „ | positive | „ |

Reversing the direction of the lines reverses the current in each case."

By discarding the idea of S lines of force the same well-known and continually-reiterated statement can be reduced to even simpler terms. As Mr. FitzGerald has been familiar with these ideas for "more than a quarter of a century," it is most singular that he persists in ignoring an essential part of the theory which he attacks.

I think, however, Sir, that we can easily arrive at a genuine *experimentum crucis*, which, when properly performed, should settle the question. I have asked Mr. FitzGerald to tell me what, according to his theory, will be the result of moving a small coil (as in the figure) between two poles of opposite name.

Relying on the universal application of the law of Lenz, he tells me that motion to and fro along the line joining the poles will generate currents alternately, direct and inverse.

On the other hand, relying on the fact that the number of lines passing through the coil will—if the pole pieces are sufficiently wide—undergo no change, I assert that no current will be produced. Perhaps Mr. W. M. Moorsom will try the experiment.

I am sorry that Mr. FitzGerald has not accepted my invitation to apply his theory to the explanation of the Siemens direct current machine, as such an explanation could not fail to be highly interesting.

Mr Nalder's very lucid discussion of the action of the Gramme ring, by reference to the principle of the conservation of energy, is quite sound and useful enough *so far as it goes.* But I do not think it is capable of rendering a very complete account of inductive action, either in this, or, still less, in many other cases. For instance, how is a "Siemens direct current" machine to be treated on this method?—Yours, &c.,

W. H. SNELL.

Liverpool, 19th February, 1884.

---

TO THE EDITOR OF THE ELECTRICIAN.

SIR: What is the use of a theory of the Gramme ring? What we want is a comprehensive theory which will explain any and every dynamo machine.

"E" states that he knows of no machine whatever in which the action cannot be expressed in terms of the addition and subtraction of lines of force. Let him show how his theory applies to, say, the Ferranti machine. Mr. FitzGerald acknowledges it to be a *sine quâ non*, that a theory should be reconcilable with known facts. Perhaps he will apply his theory to the explanation of the Elphinstone-Vincent machine.

It is scarcely credible that the cause of the generation of electricity in one class of machine should not be the cause of its generation in another class of machine, and no theory which does not rationally and satisfactorily explain the action of every dynamo will be accepted by—Yours, &c.,

Feb. 1, 1884. ONE OF THE CROWD.

---

TO THE EDITOR OF THE ELECTRICIAN.

SIR: I am much interested in the discussions now going on in your paper relative to the "theory of the Gramme ring." There are, however, many points which to my mind are not yet satisfactorily explained, and which I think might be elucidated were such a theory proved to be correct as, with your permission, I shall put before you.

I take for granted that every molecule has polarity, has a definite shape, and has a neutral plane. Now, a molecule of every known substance has resistance, and, by my theory, should have *a line or plane of least resistance*, and where is the line or plane of least resistance in a molecule of a magnet?

I have, unfortunately, neither the instruments nor the time necessary to find it out, but perhaps some one of your readers may.

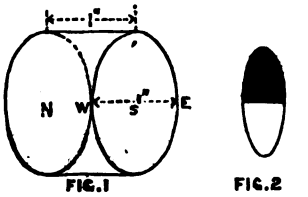


FIG.1

FIG.2

FIG.3

FIG.4

The way I should try would be as follows:—

I should obtain a piece of iron, perfectly homogeneous and as pure as possible, of 1in. diameter in section and 1in. long. Theoretically the resistances between any two points of this piece of iron, diametrically opposite and one inch apart, should be equal.

Now, if I magnetise it axially, and then take the resistances, I believe that they will differ, and that the resistances from N to S will be different from that from S to N, that the resistances from E to W will be different from that from W to E. Another point is the shape of the plane, for although I am inclined to believe that the shape of a molecule does not alter during the passage of the electric current, or currents, I am inclined to believe that the distribution of the fluid, or whatever it may be that gives it polarity, does, and that although

Digitized by Google

in some cases, as shown in the text books, the N and S are as Fig. 2, in others the N and S may be as in Figs. 3 and 4.

It is generally assumed that the molecule is oval shaped in one section and circular in the other section, as Fig. 2, and that the neutral line or plane is circular, but it might just as well be oval. I think, if extensions of the experiment which I propose were carried out, this point might be settled.

Should this theory of *a line or plane of least resistance in every molecule* prove correct (and I think Professor Hughes's experiments support it, as he found that copper, electrically deposited, had greater conductivity than that which had been obtained otherwise), I can foresee that very great changes must be made in the generally accepted explanations of electric and magnetic phenomena.

Should you care to have it, I will send you a theory which has occurred to me, as possibly showing what "resistance" may be.—Yours, &c., B.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: Referring to the communication of Mr. Desmond FitzGerald in a recent issue, I was surprised to read the following statement—if we take the final conclusion from the hypothesis—viz., that "the addition to a coil of lines of force coming from a north pole causes a current to flow in one direction, whilst the addition of lines coming from a south pole produces a current in the contrary direction." *Experiment at once flatly negatives this conclusion.* This experiment is described at the end of the same article, where Mr. FitzGerald says that on inserting the north pole of a magnet into a coil of wire in circuit with a galvanometer he obtained a deflection to the right, and that on inserting the south pole of the same magnet into the coil *without reversing the direction of the magnet* he obtained a deflection in the same direction as before, *i.e.*, to the right.

I presume here that Mr. FitzGerald has not moved the magnet, but the coil, and probably in moving the latter he has not taken care to keep the same end of the coil facing the magnet; if so, the result he obtained is natural, but it does not in any way contradict "E's" theory and conclusions. For if Mr. FitzGerald will repeat his experiment so as to add lines of force to the same end of the coil, by keeping the coil fixed and reversing the magnet so as to insert first the north pole and then the south pole into the coil, he will find that the deflections obtained *are in contrary directions*, and are in accordance with the conclusions above referred to. What the result of his experiment really proves is that if you add N lines of force to one end of a coil of wire you obtain a deflection to the right say, or on adding S lines of force to the opposite end of the coil you again obtain a deflection to the right, which is not connected with "E's" conclusions. I may add that I have tried this experiment myself with a coil of many convolutions and a sensitive ballistic galvanometer.—Yours, &c., P.D.

February 7, 1884.

## PRIMARY BATTERIES.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: Mr. Desmond FitzGerald's letter in *The Electrician* of February 9 contains ten asseverations, but only three main points which affect the question of zinc consumption in primary batteries.

The first of these is an admission that there is *not* a "back electromotive force" of 1·49 volt generated in "each cell of a battery." Then how is the electro-chemical equivalent of hydrogen or of zinc, or the consumption of zinc in a battery of, say, 60 cells affected by the fact that water requires a minimum E.M.F. of 1·49 volt to decompose it?

Mr. FitzGerald re-asserts that "the passage of a given current for a given time necessitates the consumption of the same quantity of zinc in *any* voltaic or other electrolytic cell whatever, whether the zinc be acted upon by nitric, or by sulphuric, or by muriatic acid, or by any combinations of these acids." But Faraday himself demonstrated the contrary, as shown in my former letter, by a series of experiments ("Experimental Researches," 1,137-40), in which the amount of zinc consumed whilst producing an equal amount of electric energy and decomposing an equal volume of water in the voltameter *varied* from 72·8 parts to 186·4 parts, according as it was acted on by dilute nitric or sulphuric acid, and the numerous other investigators to whom I referred have disproved it in other ways.

In the well-known but inaccurate formula $W = z C t$, I should have stated that C represents the current, not in amperes but in watts (volt-amperes).—Yours, &c.,

O. C. D. ROSS.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: I am not an electrician, but I employ galvanic batteries for surgical and lighting purposes. I notice in a recent number of your journal a note in reference to the regulation of the internal resistance of a battery by the addition of alcohol, as suggested by Mr. Beeman. I have for two or three years mixed spirit of wine with the solutions of my batteries, and the idea originated in this way:—To be brief, I had charged a new battery with fresh solution, and soon after a very unpleasant odour emanated from the battery. I disposed of this solution and recharged the battery with fresh liquid; at the same time, having some spirit of wine standing by, I threw a little into the battery, thinking it might help to prevent the objectionable odour. As time went on I noticed, as I thought, that not only was the force of the battery thereby increased, but the exciting solution appeared to maintain its action longer. I have therefore mixed alcohol with my solutions since. I have never systematically compared my battery thus charged with another charged in the ordinary way, I should therefore like to know the results of any further experiments that may be made in this direction.—Yours, &c.,

C. J. BOYD WALLIS.

23, Brook-street, Grosvenor-square, W., Feb. 18, 1884.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: Can any of your readers inform me if they know of a primary battery which will remain in action, say, two months, and will light a 3 candle-power incandescent lamp for about 15 minutes each day?

I have tried some of the bichromate two-fluid forms, but find the E.M.F. falls so rapidly, though I only used them for a short time each day for about a week.—Yours, &c.,

CONSANTT.

## ACCUMULATORS.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: Herewith I give particulars of a small carbon and lead storage cell I have had in use for about eighteen months for bell ringing, &c., it being charged from two bichromate batteries every three or four weeks. It consists of two carbon and one lead plate, 3½in. by 1½in., working in a solution of muriatic acid; the carbon plates are wrapped with two thicknesses of ordinary blotting or filtering paper. The lead plate is then placed in the middle, and the spaces between it and the carbon plates (about ¼in. each side) filled up with spongy lead, deposited from a solution of acetate of lead on zinc plates. After the spongy mass is removed from the plates it is washed in muriatic acid to remove any zinc that may remain, and is then ready for use. In charging connect the lead plate with the zinc pole of battery. After charging and discharging two or three times the cell will charge to its full capacity. I have used the above very successfully for lighting a small buttonhole lamp, which it will light well for two or three hours after an hour's charge, the delivery being slow and very uniform compared with the ordinary Planté. Hoping the above may be of use to some of your readers.—Yours, &c.,

Feb. 6, 1884. E. HARVY.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: It would perhaps be hardly fair to ask you to say which (if any) of the five or six accumulators now offered is most likely to be effective in private hands; but if you would be so kind as invite reports from those of your readers who

Digitized by Google

have actual experience of these contrivances, the information would no doubt be very useful and interesting.

For myself, I am only waiting till some storage battery is pronounced a decided success, in order to utilise water power, which is available, and to introduce the electric light for domestic use.—Yours, &c.,

A DWELLER IN THE WILDERNESS.

## THE DISTRIBUTION OF CURRENT IN NETWORKS OF CONDUCTORS FOR INCANDESCENT LIGHTING.

TO THE EDITOR OF THE ELECTRICIAN.

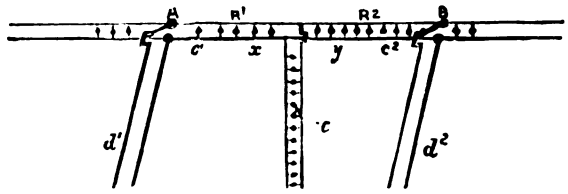
SIR: The following elementary condition will be found to be frequently involved in the network systems of conductors, maintained at uniform potential at fixed points by "feeders," which now find favour with electrical engineers.

The formula sent herewith, which I had occasion a short time since to work out, may therefore be useful to some of your readers.

In the diagram A and B are points in a network system maintained at the same potential by "feeders" $d^1$ and $d^2$.

Lamps are connected across the arms $R^1$ and $R^2$, and these arms also supply current to the arm C. It is required to know the ratio in which the current passing through C's lamps will divide between them the arms $R^1$ and $R^2$.

This will evidently depend upon two things—first, the relative resistances of the arms $R^1$ and $R^2$, and second, the relative amounts of current taken direct from these arms to supply lamps.



In the formula and diagram

Let C = current absorbed in arm C.

$x + y$ = C.

$\frac{x}{y}$ = required ratio of the component of C.

$R^1$ and $R^3$ = resistance of arms $R^1$ and $R^2$ respectively.

$C^1$ and $C^2$ = current absorbed in arms $R^1$ and $R^2$.

Then $$y = \frac{R^1 C + \frac{1}{2}(C^1 R^1 - R^2 C^2)}{(R^1 + R^2)}.$$

$$x = C - y.$$

The formula necessarily supposes the current in each arm to be taken off at a uniform rate per unit of length.—Yours, &c.,

W. B. SAYERS.

Eastbourne.

## THE METROPOLITAN BRUSH ELECTRIC LIGHT AND POWER COMPANY.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: Your last issue contains a long account of the above company's meeting on the 12th instant.

I am desirous that every one interested in electric work should fully understand that the shareholders have been induced to withdraw from electric lighting through having in my opinion the facts as regards their Holborn work misrepresented to them.

The investigation committee have told the shareholders that the estimate for the Holborn work was rotten.

It will perhaps be sufficient evidence to the contrary for most of your readers that my estimates, prepared in the first instance with great care, were subsequently checked by tender and prices of well-known firms, such as Siemens Brothers, Hick Hargreaves, Johnson and Phillips, the India Rubber Company, &c., and that they were reported on to the largest original shareholder in the company, and the Board, by Mr. R. E. Crompton, whose report, which was very lengthy, stated that both as to capital and revenue I had a very large margin.

And further, there were substantial men of business who had gone into the scheme and were prepared to find half the capital for the Holborn work, yet such was the state of mind the shareholders had been put into by the committee that they would not listen to anything save a purely law policy.

The meeting listened whilst they were being told that provisional orders were worth nothing, and that the Holborn work could only result in loss, and that they had better sacrifice the whole of the money spent on provisional orders, and do nothing save put all their eggs into the one basket of law. And yet they would not even give a hearing to the biggest shareholder—who only became a member of the Board because he was such—whilst he tried to explain how they could keep alive their work and make profit out of their provisional orders. Possibly when the balance-sheet showing all the results of the law policy and the money thrown away on parliamentary work comes to be considered there may be a few regrets.

The point chiefly interesting to your readers is that, beyond any competent question, it is wrong to state that under proper arrangements the Holborn work would not have been profitable. Reliable opinion conclusively establishes the contrary. There is, and always must be, in every trade enterprise a certain uncertainty as to demand, but the facts as regards the number of lights to be obtained at Holborn were misrepresented to the shareholders.—Yours, &c.,

RADCLIFFE WARD.

110, Cannon-street, London, E.C.,
February 21, 1884.

## SIR C. BRIGHT AND THE GAULARD-GIBBS SYSTEM.

TO THE EDITOR OF THE ELECTRICIAN.

[The following correspondence has passed, on the subject of Messrs. Gaulard and Gibbs's system of electric lighting by induction coils, between Messrs. Gaulard and Gibbs and Sir Charles Bright, the English President of the Société Internationale des Électriciens, and has been sent to us for insertion.—ED. *E.*]

18, Warwick-street, Regent-street, W.,
London, February 18, 1884.

To the President of the English Section of the International Society of Electricians.

Sir: At its meeting of the 6th inst., the International Society of Electricians had on its list of subjects for discussion Messrs. Gaulard and Gibbs's secondary generators. In bringing the subject forward the committee thought that the first attempts which had successfully realised the distribution of electrical energy of varying potential would be specially interesting to the members of the society, and upon the invitation of our respected chief, Mr. Tresca, Mr. Gaulard placed himself at the disposal of the meeting to furnish the most complete explanation of our apparatus.

As you yourself were present at this first meeting, you would be able to appreciate the importance which the entire meeting attributed to the determination of the loss resulting from the transformation of energy by means of the secondary generators. The proofs produced by Mr. Gaulard at the meeting are worthy of examination, and we should fail in our duty as members of the society if we did not encourage every inquiry that might enlighten our colleagues.

We address ourselves to you, therefore, in the common interest which we have all agreed to support, as founders of the International Society of Electricians, whose future development will be maintained on a level with the general progress which it is intended to guide, and we request that you will name a day and hour when it will suit you to come to Edgware-road Station to verify the results obtained from the secondary generators which are at work each day from half-past four p.m. to one o'clock a.m.

Should you consider it desirable to bring with you Mr. Preece, who is, as you know, a member of the English Com

REESE LIBRARY OF THE UNIVERSITY OF CALIFORNIA.
Digitized by Google

mittee, we shall be extremely pleased to place ourselves entirely at your disposal.

We are, Sir,

Your most obedient servants,

Gaulard.

J. Dixon Gibbs.

31, Golden-square,

London, W. 21st February, 1884.

Gentlemen: In answer to your letter of the 18th inst. addressed to me as honorary president for England of the Société Internationale des d'Electriciens, I beg to inform you that I have already declined a similar request, respecting another invention, addressed to me in the same capacity; and I can only reply to you in like manner, namely, that it is impossible for me to spare the time to investigate and verify details of electrical inventions unless brought to me to report upon professionally.

When I remind you that during the last month 90 electrical inventions were patented, I think you will see that, if I commenced to undertake or verify experiments as English president of the society, the honorary office might soon become excessively arduous.

Moreover, in the case of your appliances, I think it would be better for you to arrange with some other electrician to take in hand any verification of results for you, inasmuch as about five-and-a-half years ago I invented the system of distributing electricity by secondary generators which you employ.

I refer you, hereupon, to my printed specification of October 22, 1878, No. 4212, for "Lighting by Electricity," from which the following is an extract:—

"At each point where the electric light is used, the light or a group of lights, is actuated by the secondary coil or coils of an induction apparatus fixed there.

"The primary coil of each induction apparatus is in circuit with a metallic main conductor, common to all, and connected with an electric battery or a magneto-electric machine, which generates the current at any convenient locality.

"The size and length of the primary and secondary coils of the induction apparatus are adapted to the number of lights employed at each point where the secondary currents actuate the electric light."—I am, Gentlemen, yours faithfully,

Charles T. Bright.

Messrs. Gaulard and Gibbs,
The National Company for the Distribution of Electricity by Secondary Generators,
Limited, 18, Warwick-street, W.

## PROFESSORS AYRTON AND PERRY'S FORMULÆ.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: Kindly allow me space to ask Mr. H. D. Wilkinson to look again at the formulæ, for he certainly has misunderstood them in more points than one, the last being when he states that—

"The current supplying both consumers only traverses the resistances $R + r'$," for if this is true, then the conductors between M, N, and $m$, $n$ can have no resistance.—Yours, &c.,

E. E. A.

## OVERHEAD OR UNDERGROUND TELEPHONE WIRES.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: In your leader of January 26 there are some very strong and timely arguments on this subject; but the report of a meeting of the United Telephone Company in the same issue affords very strong evidence that the question wants ventilation. The chairman, in his speech, explained to the shareholders why the directors had decided to introduce a private Bill into Parliament to obtain powers to fix wires overhead and underground. In the course of his explanation he said:—"As we proceeded with our work we found the difficulty of carrying on the business with these overhead wires growing constantly. We do not want, of course, to ride roughshod over any one's property or rights, or even their susceptibilities; but of course we want some due regulations made;" and further on, "If we had the requisite authority to cross the houses and streets in a proper way, our wires would by no means disfigure the streets."

Now, it will seem very premature to apply to Parliament for the power they want until they show distinctly how they will use it. It is frequently urged already that they do "ride roughshod over any one's property or rights," not to speak of their "susceptibilities," wherever they can get their wires fixed by hook or by crook. So what will they do if they get armed with an Act of Parliament? And as regards the "regulations" referred to above, they all seem to come under one denomination, viz., more power, legal power; and for such powers all they seem to propose on the other side is that the Board of Trade shall be made responsible in case of accidents. I am sorry if this is not a fair view of the policy shadowed in the report I have carefully read, and, if not, perhaps some of your readers will correct me. In the hope of such correction or assistance I beg to point out several doubts and difficulties that arise in trying to understand the position and the past and future policy of the United Telephone Company.

In the first place, the chairman speaks of the constantly growing "difficulty" of getting permission to fix overhead wires as at present, and plaintively urges that "*they would by no means disfigure the streets*," but would "*cross the houses* and streets in a *proper way*" if they "had the *requisite authority*." Now, there may be some extraordinary explanation of this apparent contradiction. But why should they delay to let the public know why they have all along been fixing their wires in an *improper* way, and absolutely require parliamentary power before they can fix them in a *proper* way?

They hope, no doubt, "with the aid of counsel and science," as their vice-chairman stated, "to dissipate all the fears which seem to be entertained" about the overhead wires, and their chairman seems to think they will even be able to invest them with artistic merit, but not without a special Act of Parliament.

London, surely has a right to know the reason.

The chairman continued, "*Of course*, one reason of our going to Parliament for a Bill is because it is said that we can lay our wires underground, and carry on our business just as effectually, without any of the trouble and annoyance which they say exist from overhead wires. We know very well that communication can take place under certain circumstances by underground wires, but it is not established at all satisfactorily that underground communication is as good as overground for telephone purposes."

Now, this most extraordinary "reason" for the Bill is completely outdone by one still more—say, parodoxical. It is this:—"If we had the power, the streets, as a matter of fact, are already occupied."

Little more need be added to show that to those of your readers who feel a serious interest in the question the matter becomes very alarming. And to those who have not it must appear an amusing puzzle.

The vice-chairman, however, makes a statement that complicates the question still more, for he says:—"Some one has said—I am not a scientist, and therefore do not know whether the statement is correct—that if you put a telephone wire under the earth, you diminish its value by fifteen times out of sixteen."

And what, then, is the "value" of the overhead wires for telephone purposes? Well, it is not much consolation when he says that "We know that a small change in the atmosphere, the neighbourhood of some building, or telegraph wire will interfere with it."

If an enemy were to say this no one would believe it. But if it is not a gross exaggeration, what hope is there for the present users of the telephone ever getting relief from the present troubles which they are continually complaining of?

Is it possible to imagine that the company want to put a few wires underground in order to establish an excuse for the continuance of the present unsatisfactory working of the system? Now these two gentlemen, whose statements I have quoted, being at the head of such a wealthy and powerful company—not to speak of their other more influential positions—have the means of getting the best information that the telephone

Digitized by Google

world can impart, and yet the statements they make are enough to make even outsiders melancholy. If they hope to persuade a Parliamentary Committee, by the "aid of counsel and scientific witnesses," to grant them the powers they seek for, why not take their customers—the public—into their confidence, and let *them* have some scientific consolation? In the newspapers they (the company) call the Post Office "the dog in the manger," because they enforce severe restrictions. How is their own policy to be characterised when they persistently refuse to sell their instruments at any price, charge an almost prohibitory annual rental, and, in many cases, refuse to let well-known old and wealthy firms have them on any terms? Is this not what they call the dog in the manger policy?

But there is another dogged policy, that of "the dog and the shadow," and it may be that whilst the company are endeavouring to grasp at that panoramic mirage that seems so far above and beyond the dog and shadow policy, they may—I mean the shareholders may—lose the substantial and vast business that would be more profitable and less irksome. That is by selling instruments out and out at a large profit to all comers.

Besides, the old patent law has been fearfully strained in their hands.

There is an unwritten law pervading even the old Acts that have secured so many hard and fast monopolies to past inventors. But their custom has been to let the public have their inventions, with the sole proviso that they would pay at the most a fancy price.

The United Telephone Company are not content even with their pound of flesh, but they must have more law. It may be well, perhaps, to remind them that there are many ways in which— MOS LEGEM REGIT.

## HEAT GIVEN OUT BY INCANDESCENT LAMPS.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: Could any of your correspondents kindly inform me in what books or papers I could obtain information on what I think is a very little investigated subject?

I have almost invariably found that with a given incandescent lamp, when it is run at a high candle-power, the hand placed near or on the bulb experiences *less* heat than when the same lamp is run at a considerably lower candle-power.

I have what appear to me several easy explanations for the above, but perhaps it may be a subject in which a correspondent may be able to give me a more satisfactory explanation.—Yours, &c., ENQUIRER.

## HOUSE LIGHTING.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: Being deeply interested in the subject of electric lighting for household purposes, but in doubt on the questions mentioned below, I shall esteem it a favour if you or some of your numerous correspondents would set my doubt at rest by giving me answers to these questions:—

1. Are cells charged on the Leclanché principle *capable* of lighting a Swan or other incandescent lamp?

2. If so, what number of (interior) cells 6in. by 2in. would be requisite to work 5, 10, 15, and 20 candle-power lamps respectively, and how long, using them 6 to 8 hours per night, would they continue in effective action without recharging?—

—Yours, &c., P. A. SMYTH.

25, Hamilton-street, Belfast,
12th Feb., 1884.

## WATCHMEN'S DETECTORS.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: The article on Fletcher's watchman's detector in last week's *Electrician* calls for a few remarks.

In the first place you refer to Elliott's detector, as described in Vol. VIII., p. 11, in a sense (of course unwittingly) unjust to precedent inventions. Fourteen years ago I designed and made a watchman's detector exactly the same as Elliott's. I invented it to order for Messrs. Nobles and Hoare, the great varnish makers, of Cornwall-road, Blackfriars, and it has been the means of detecting negligence in watchmen frequently. Every morning a sheet of paper is taken off the drum, with a perforated record of the time of his visits to each of the thirty places he has to call at to complete his round, and as he must visit each every hour, there are 360 records made every night. At each place that he visits there is simply a common electric bell "push," and yet the most expert electrician could not devise a dodge to enable the man to shirk his duty. On one occasion they found out a tricky watchman, although he had procured a duplicate key of the office in which the tell-tale was locked.

I am told they have tried every kind of "tell-tale" or "detector," but cannot depend on any other. A bell-hanger in the same street has kept all in order for the last thirteen years.

Now, with regard to the apparatus invented by Mr. Fletcher, it is a pity that there is not only a vulnerable point in the scheme, but it is also exposed in a way to enable any one to render entirely nugatory all the pieces of ingenious apparatus described under Fig. 1. Surely Mr. Fletcher does not need to be told that two insulated wires can be put in contact instantly without removing visibly any of the insulating material.

Not only so, but it is one of the delights of juvenile electricians to put men up to the trick. If means cannot be found to render the apparatus more serviceable, the expense would be worse than wasted.—Yours, &c.,

WALKER MOSELEY.

12, Queen's-road, St. John's Wood.

## A QUESTION OF PATENTS.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: In your issue of January 26, on page 256, Mr. Frank Wynne, manager of the Anglo-American Brush Light Corporation (Limited) states, with respect to a specially designed dynamo for incandescence lighting, "it embodies the electrical patents of Schuckert, Mordey, and others, which are the property of the corporation."

Doubting the statement regarding the Schuckert machine, I wrote to Herr Schuckert, and the following reply has been received:—

"Respecting the Anglo-American Brush Company, I beg to state that that company never yet bought any of my patents. I have, however, written to them, and expect their reply, as I intend to publish the falseness of such wide-spread assertions."

If you will find room for the above I shall be obliged.—Yours, &c., W. E. TEALE.

Managing Director of the Simplex Electric Light and Plant Company (Limited).

Feb. 7, 1884.

## THUNDERSTORMS.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: In reference to your digest of Professor Tait's lecture on "Thunderstorms," in your issue of January 26, the lecturer says, "As to the curious phenomenon known as 'globe lightning,' they knew little about it, as they had never been able to produce it by experiments." During the last of the ten years that I had the honour of carrying out the experiments of the late William Spottiswoode, P.R.S., we came across a very curious and beautiful effect of a current of high tension and quantity combined, passing in air, resembling the "globe lightning" referred to, and which Mr. Warren De la Rue has also noticed in his experiments with his great chloride of silver battery. On investigating the above phenomenon Mr. Spottiswoode came to the conclusion that it was analogous to the natural phenomenon, in which view I believe Mr. De la Rue also coincides.

We were experimenting with my "electric valve" (an account of which is given in Mr. Spottiswoode's last physical paper to the Royal Society), with regard to how far we might increase the density of a gas in a glass tube, through which a statical discharge was passing, without impairing the efficiency of the valve. We employed an induction coil, capable of

Digitized by Google

giving a 26in. spark in air, excited by one, two, three, four, or five De Meritens rings arranged in parallel *connection* (I avoid the conventional term "arc," as I consider its indiscriminate use to be misleading), and the induced discharge in the secondary, in alternate directions, was divided and laid parallel or in one direction by my valve, and passed through two or only one red light.

By means of my glycerine or plumbago-slate shunt (graduated resistance from zero up to 6,000,000 ohms) we were enabled to shift this nebulosity to almost any part of the tube, and by certain adjustments we were enabled to cause a continuous movement of the same, the thing travelling for a certain distance—rapidly or slowly, as we desired—along the space in the tube, suddenly vanishing in space, giving birth to another luminosity, also in space, and *not* from a terminal, in a remote portion of the tube.

So intense was the heat from these glows, or balls, that unless they were kept moving about I had to construct other tubes, as was desirable, in consequence of the ones in use being *melted* in the part immediately opposite the tube. The discharges were in number about 30,000 per minute, and as they passed through the tubes some splendid effects were produced. We began with about four millionths of an atmosphere pressure, and gradually increased the pressure by admitting measured charges of atmospheric air, and when we had increased the pressure to half an atmosphere the discharge broke up into three separate isolated "entities," as Mr. De la Rue has named them, of brilliant luminosities, giving out intense heat. (The dimensions of the tubes employed for investigation were 2ft. long by 4in. diameter, with large, solid, aluminium terminals.) As the pressure was increased the luminosities grew narrower in diameter, and shorter in length, till there was only one isolated cylinder, with hemispherical ends, of 1in. in length by ¼in. in diameter, in the middle of the tube of brilliant temporary sojourn of an "entity."

I think these facts will at any rate modify the opinions of your readers as to the want of evidence respecting the nature of "globe lightning."—Yours, &c., PAUL WARD.

24, Woodlands Park-road, Greenwich, Feb, 1, 1884.

[We are again compelled to leave over letters from Messrs. Anderson and Munro, and Mr. Hutchinson, relating to Overhead Wires.]

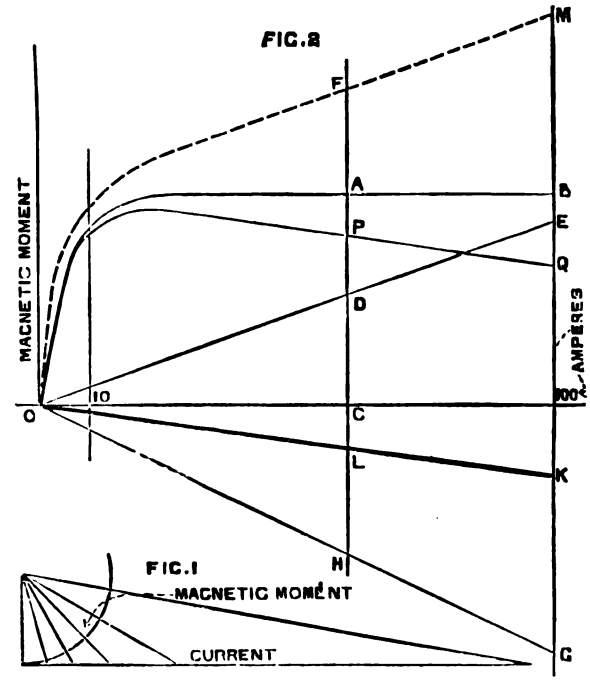
---

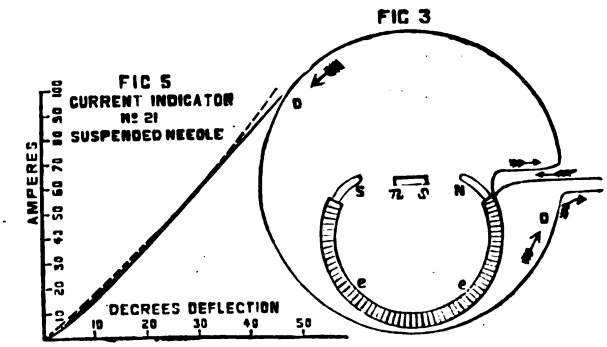
## NEW INSTRUMENTS FOR MEASURING ELECTRIC CURRENTS AND ELECTROMOTIVE FORCE.*

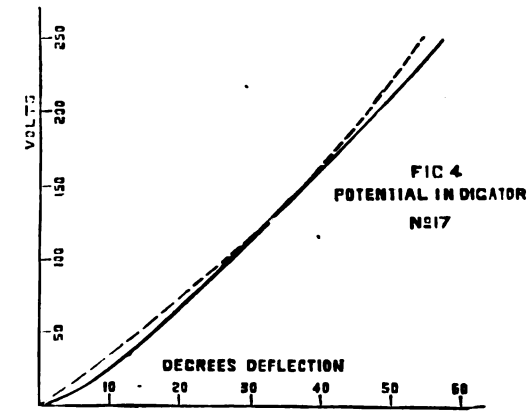
BY A. CROMPTON AND GISBERT KAPP.

In consequence of the rapid development of that part of electrical science which may be termed "heavy electrical engineering," reliable measuring instruments specially suitable for the large currents employed in lighting and transmission of energy have become an absolute necessity. As usual, demand has stimulated supply, and many ingenious and useful instruments have been invented, the manufacture of which forms at the present day an important industry. Mr. Shoolbred, in a paper which he recently read before this society, gave a full and interesting account of the labours of our predecessors in this field. To-day we add to the list then given a class of instruments invented by us, examples of which are now before you on the table. We have preferred to call them current and potential indicators in preference to meters, considering that the latter term, or rather termination, ought to be applied rather to integrating instruments, which the necessities of electric lighting, we believe, will soon bring into extensive use. The principal aim in the design of these indicators has been to obtain instruments which will not alter their calibration in consequence of external disturbing forces. If this object can be attained, then it will be possible to divide the scale of each instrument directly into amperes or volts, as the case may be, and thus avoid the use of a co-efficient of calibration by which the deflection has to be multiplied. This is an important consideration when it is remembered that in many cases these instruments have to be used by unskilled workmen, to whom a multiplication involving the use of decimal fractions is a tedious and in some cases even an impossible task.

All measurements are comparative. We measure weights or forces by comparison with some generally known and accepted unit standard weights, lengths, areas, and volumes by comparison with a unit length, resistance by a standard ohm, and so forth. In the same way currents could be measured by comparison with a standard current; but this would be a troublesome process, not only on account of the apparatus necessary, but also because it would be a matter of some difficulty to have a standard current always ready for use. In general, measurement by direct comparison with a standard unit is discarded for the more indirect method of measuring, not the current itself, but its chemical, mechanical, or magnetic effect. The chemical method is very accurate if a proper density of current through the surface of the electrodes be used,* but since it requires a considerable time, and, above all, an absolutely constant current, its use is almost entirely restricted to laboratory work and to the calibration of other instruments. For practical ready use, instruments employing the mechanical or magnetic effect of the current are alone suitable. We weigh, so to speak, the current against the force of a magnet, of a spring, or of gravity. The measurement will be exact if the thing against which we weigh or counterbalance the current itself retains its original standard value. Where permanent magnets or springs are used as a balancing force, this condition of constancy in our weights and measures is not always fully maintained, and to make matters worse, there is no visible sign by which a change, should it have occurred, can be readily detected. A spring may have been overstrained, or a steel magnet may have become weakened, without showing the least







* Paper read before the Society of Telegraph Engineers, 14th February, 1884.

* According to recent experiments made by Dr. Hammerl, the density of current in a copper voltmeter should be half an ampere per square inch of surface.

Digitized by Google

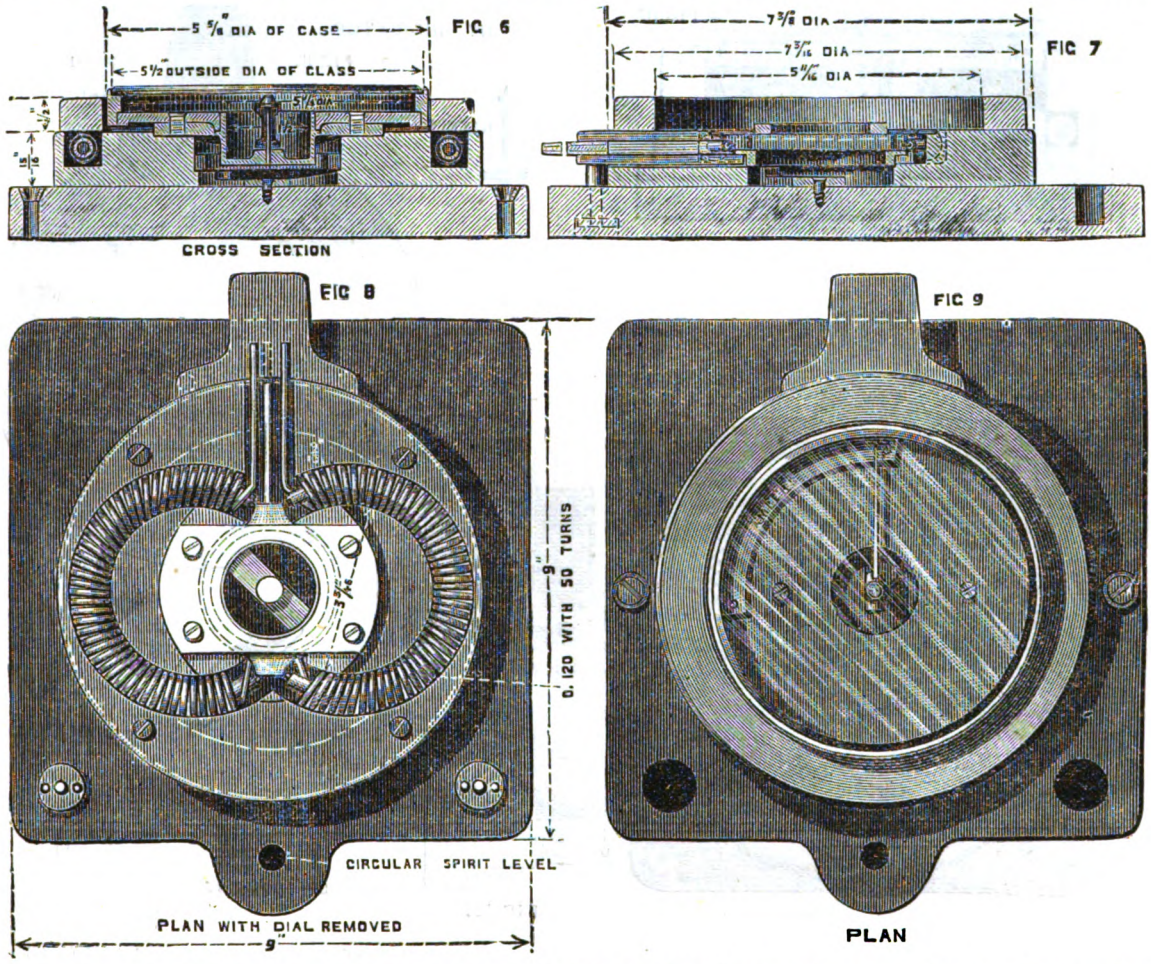
alteration in outward appearance. To overcome this difficulty, the obvious remedy is not to use springs or steel magnets at all, but to substitute for these some other force which should be either absolutely constant, such as the force of gravity, or at least should vary only within narrow limits, and this in accordance with a definite law. This latter condition can be fulfilled by the employment of electro-magnets.

To imitate with an electro-magnet as nearly as possible a permanent magnet, so that the former can be used to replace the latter, it is necessary that the magnetism in the iron core should remain constant. This could, of course, be done by exciting the electro-magnet with a constant current from a separate source. (In a recent note to the Paris Academy of Science, M. E. Ducretet described a galvanometer with steel magnet, which is surrounded by an exciting coil. When re-calibration appears necessary, a known standard current from large Daniell cells is sent through this coil during a certain time, and thus the magnet is brought back to its original degree of saturation. M. Ducretet also mentions the use of a soft iron bar instead of a steel magnet, in which case the current from the Daniell cells must be kept on during the time an observation is taken.) But such a system would appear to be too complicated for ready use. Moreover, some sort of indicator would be required by which we could make sure that the exciting current has the normal strength.

The plan we adopt is to excite the electro-magnet by the whole or a part of the current which is to be measured. Since this current varies, the power exciting the core of the electro-magnet must also vary; and since we require the core to have as nearly as possible a permanent magnetic force, we are brought face to face with the question, whether an electro-magnet can be constructed that has a constant moment under varying exciting currents. This question has been answered by the well-known experiments of Jacobi, Dub, Mueller, Weber, and others. To get an absolutely constant magnetic moment is not possible, but between certain limits we can get a very near approximation to constancy.

The relation between exciting power and magnetic moment is very complicated, depending not only on the dimensions and shape of the core and the manner of winding, but also on the chemical constitution of the iron of the core. It is not possible, or at least it has hitherto not been found possible, to embody all these various elements into an exact mathematical formula, which would give the magnetic moment as a function of the exciting current; but the above-mentioned experiments have shown that within certain limits, and in the neighbourhood of the point of saturation, the relation between the two is that of an arc to its geometrical tangent. It will be seen that for large angles the arc increases much slower than the tangent; that is, for strongly excited cores, a very large increase of the exciting current will produce only a slight increase of magnetic moment. If Müller's formula were correct for all currents, absolute saturation could only be reached with an infinite current. Whether this be the case or not, it is certain that the greater the exciting current the less will a variation in it affect the magnetic moment of the core. To imitate as nearly as possible permanent steel magnets, it is therefore necessary to use electro-magnets, the cores of which are easily saturated. The core should be thin and long, and of the horse-shoe type; the amount of wire wound round it should be large in comparison with the size of the core.

Here is a magnet partly wound which was used in one of our earliest experiments, but which was a failure on account of having far too much mass in the core in comparison with the amount of copper wire wound round it. Since then we have greatly diminished the iron and increased the copper. The cores of the instruments on the table are composed of two or three No. 18 B.W.G. charcoal iron wires, and are wound with one layer of 0·120in. wire in the case of the current indicators, and eighteen layers of 0·0139in. wire in the case of the potential indicator. If from the diagram (Fig. 1) we plot a curve the abscissæ of which represent exciting current, and the ordinates magnetic moment of the soft iron core, we find that a considerable portion of the curve is almost a straight and only slightly inclined line. If it were a horizontal straight line the core would be absolutely saturated, but such as it is, it answers the purpose sufficiently well, for with a variation of exciting current from 10 to 100 amperes the magnetic moment varies but slightly. If a small soft iron or magnet steel needle, *n s*, be suspended between the poles S N of an electro-magnet of such proportions as described above, and the current after exciting the electro-magnet *e e* be led round the coils *d d*, it will be found that for all currents between 10 and 100 amperes the needle *n s* shows a



definite deflection for each current. Here we have a galvanometer with permanent calibration. In this case the deflection of the needle will not strictly follow the law of tangents, because the directing power of the electro-magnet is not absolutely constant; but whatever the exact ratio between deflection and current may be, it must always remain the same, and to each angle of deflection corresponds one definite strength of current.

The force with which the electro-magnet tends to keep the needle in its zero position, that is, in line with the poles S N, is due partly to the magnetism of the core, which is nearly constant, and partly to the magnetic influence of the coils *e e* themselves, which is, of course, simply proportional to the current. The total magnetic force acting on the needle is therefore represented by the sum of these two forces, and consequently not nearly so constant as might be desired in order to get a good imitation of a tangent galvanometer with a permanent magnet. In the diagram (Fig. 2) the curve O A B represents the magnetic moment of the iron core, the straight line O D E that of the exciting coils *per se*, and the dotted line O F M the sum of the two, obtained by adding for every current O C the respective ordinates C D and C A.

$$C F = C D + C A.$$

The rise of this curve shows that the force which tends to bring the needle back to its zero position increases with the current, though at a slower ratio than the deflecting force of the current. It follows from this,

Digitized by Google

that for large currents the increment in the angle of deflection is comparatively small, and the divisions on the scale whereon the current is to be read off would come too near together to allow accurate readings to be taken. In other words, the range of accurate reading in an instrument so constructed would only be limited. But it is very easy to eliminate the magnetic effect of the coils of the electro-magnet on the needle by introducing an opposite magnetic effect, so that only that part of the force remains which belongs to the soft iron core proper. One way of doing this is by surrounding the needle with a coil, the plane of which is at right angles to the line S N, and coupling this coil in series with the deflecting coil *d d*. If the proportions of this transverse coil and the direction of the current through it be properly chosen, its magnetic effect can be made to exactly counter-balance that of the exciting coils *e e* without perceptibly weakening the magnetism of the iron core. But instead of employing two coils, one parallel and the other transversely to the zero position of the needle, we can obtain the same result in a more simple manner with one coil only, if this be placed at such an angle that its magnetic effect can be substituted for the combined effects of the two coils. In other words, we set the deflecting coil *d d* at a certain angle to the zero position of the needle.

A similar arrangement, though not precisely for the same purpose, has already been suggested and tried by Messrs. Deprez, Carpentier, Ayrton and Perry, in galvanometers with permanent steel magnets. If the coil *d d* be so placed, the deflecting force which now acts obliquely can be

considered as the resultant of two forces, one acting at right angles to the line S N, as in an ordinary galvanometer, and the other parallel to this line, but in a sense opposed to the action of the electro-magnet and its exciting coils. If the angle of obliquity be so chosen that this latter component exactly equals the magnetic effect of the exciting coils *per se*, an equality which holds good for all currents, then we shall have an almost perfect imitation of a tangent galvanometer with permanent magnets. But we can go a step further than this; we can overbalance the exciting coils by setting the deflecting coil at a greater angle than necessary for the mere elimination of the former, and thus attain that an increase of current results in a slight weakening of the field in which the needle swings, thus allowing the increment of the angle of deflection to be comparatively large even for large currents. In this way it is possible to obtain a more evenly divided scale than in the case when the deflection follows the law of tangents, as in an ordinary tangent galvanometer. This principle of overbalancing the exciting coils is shown on diagram (Fig. 2). The straight line O G respresents the magnetic effect on the needle of that component of the deflecting force which is parallel, but in sense opposed, to S N; as mentioned above, the magnetic effect of the exciting coils is represented by the straight line O E. The combined effect of these two forces on the needle is represented by the line of O K, the ordinates of which must be deducted from those of the curve O A B, in order to obtain the total directing force due to each current. This is shown by the curve O P Q shown in a thick, full line. This curve shows how the directing force or strength of field in which the needle swings decreases with an increasing current. That this does actually take place can easily be proved by experiment.

Fig. 4 shows two curves; the one drawn in a full line is obtained by plotting the deflection in degrees of the needle of a potential indicator as abscissæ, and the corresponding electromotive forces measured simultaneously on a standard instrument as ordinates; the dotted line shows what this curve would be with an ordinary tangent galvanometer.

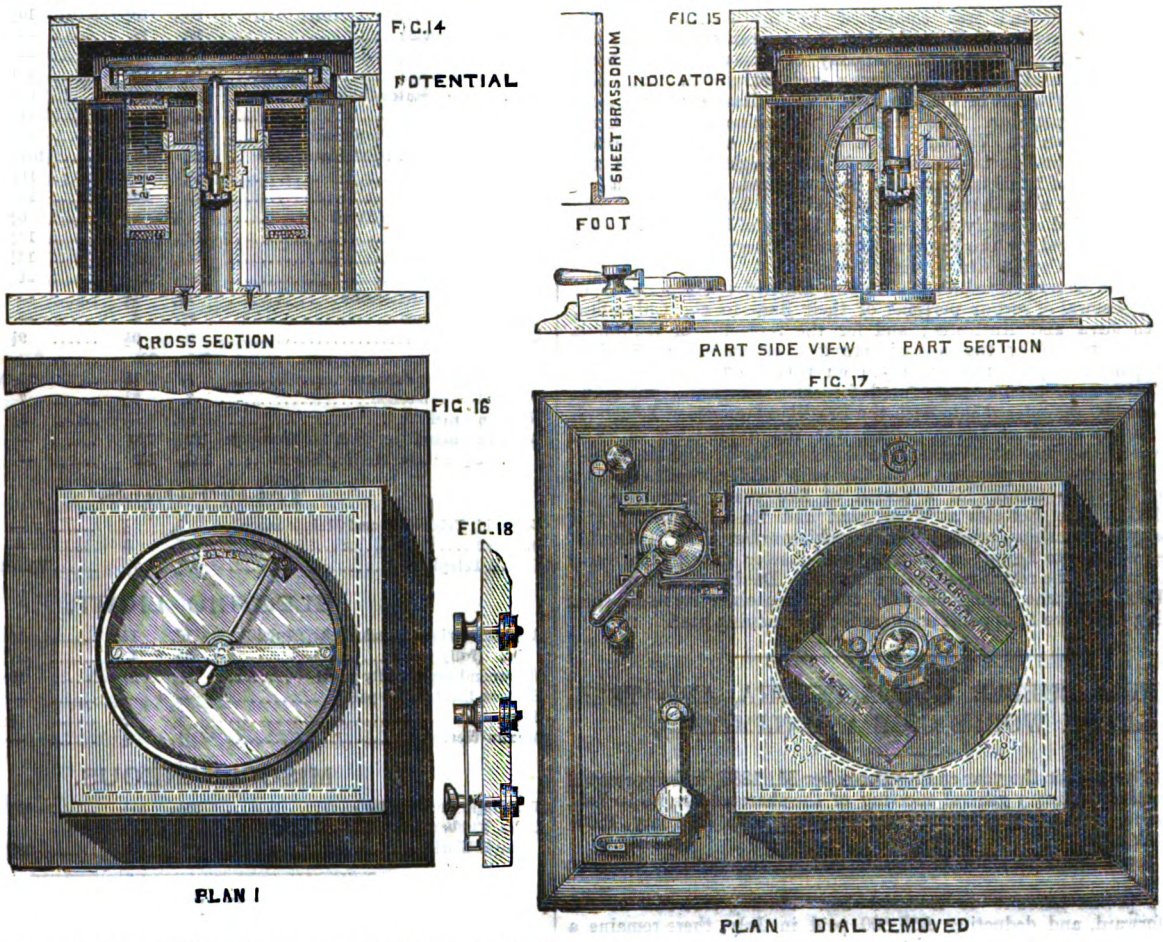
The needle of the potential indicator is mounted at the lower end of a steel axle, to the upper end of which is fastened a light aluminium pointer, whereby the deflection of the needle can be read off on a scale divided directly into volts. The scale is placed within a circular dial plate with glass cover, giving sufficient room for the pointer to swing all round, and the needle is placed within a central tube fitting it closely, which acts as a damper and so makes the instrument almost dead beat. Tube and dial are in one casting. The electro-magnet is of horseshoe form fastened to a central tubular stand, which also serves to support the two deflecting coils, one on either side of it. The tube within which the magnetic needle swings is inserted into the stand, which is bored out to the external diameter of the tube. The electro-magnet and deflecting coils are wound with from 50 to 100 ohms of fine insulated copper wire, and an additional resistance coil of from 450 to 900 ohms of German silver is added, which can, however, be short circuited by depressing a key when the instrument has to be used for reading low electromotive forces. In this case the indication of the pointer must be divided by ten. If a current be sent through the instrument the wrong way, the needle turns through an angle of 180deg., and thus brings the pointer to the side of the dial opposite to where the scale is. In this position no reading can be taken, and to facilitate the sending of the current in the right direction a commutator is added, and the same is so coupled up that when the pointer stands over the scale the handle on the commutator points to the positive terminal screw. Since the core of the electro-magnet requires a certain minimum of current to become saturated, there is a limit of electromotive force below which the indicator fails to give reliable readings. For instance, an instrument wound with 100 ohms of copper wire and 900 ohms of German silver can be used for electromotive forces varying between 300 and 3 volts, but would not be reliable for measuring less than 3 volts.

For very exact measurements the instrument should be placed north and south, in the same position in which it was calibrated; and it should not be placed close to strong currents, magnets, or masses of iron. Two different patterns of current indicators are on the table; one with double needles suspended on a point in the way compass magnets are suspended, the other with one lozenge-shaped needle mounted on an axle and pivoted on jewels, in every way similar to the needle of the potential indicator first described.

For measurements of currents from 10 amperes upwards, there is no need to employ a complete coil as the deflecting agent; one half coil or one strip passing close under the needle gives sufficient deflecting force,

Digitized by Google

and thus the construction of the instrument is rendered extremely simple. The current, after entering at one of the flat electrodes, splits in two parts, each part passing round the winding of an electro-magnet of horseshoe form, the similar poles of both magnets pointing towards each other and towards the needle. After traversing the winding, the current unites again, and passes through a metal strip close under the needle, and finally out of the instrument by the other electrode, which lies close under that at which the current entered, but is insulated from it by a sheet of fibre. The metal strip is set at an angle, to balance or overbalance, as may be preferred, the magnetic influence of the exciting coils. The effect of this overbalancing is shown in Fig. 5, where the full curve represents the current as a function of the deflection—obtained by comparison with a standard instrument—and the dotted curve shows what that relation between deflection and current would be if the law of tangents held good for these instruments. It will be seen that, about the middle of the scale, the dotted line coincides nearly with the full line, whilst at the extreme end of the scale the dotted line is higher. From this follows, that if we compare our indicator from which this curve was taken with any form of tangent instrument showing an equal angle of deflection at the medium reading, it will be seen that the needle of our indicator will be deflected to a greater angle at high readings than that of the tangent galvanometer. Consequently, the divisions on the scale will be widest apart in our instruments which greatly facilitates high readings. The current indicator and the potential indicator are fully illustrated by the engravings Figs. 6 to 18.



## THE SWAN UNITED ELECTRIC LIGHT COMPANY (LIMITED).

An extraordinary general meeting of this Company was held on Friday, the 15th inst., at the Guildhall Tavern, Gresham-street, Colonel Trevor in the chair.

The SECRETARY having read the notice convening the meeting,

The CHAIRMAN said that the object of the resolution was fully explained by Mr. Forbes at the last meeting, and therefore it would not be necessary for him to detain the meeting by going over the same ground. He might, however, mention that both of the companies—the Swan and the Edison—had obtained some provisional orders, and it was thought that there might be a difficulty in the amalgamated companies carrying them out, and therefore it had been deemed advisable to apply for an Act of Parliament. He might say that those difficulties had now been practically overcome, but, at the same time, to put the directors in a safe position, he asked them to confirm the following resolution, viz.:—"That the Bill which is proposed to be introduced into Parliament in the ensuing Session, intituled 'A Bill to transfer to the Edison and Swan United Electric Light Company (Limited) certain rights, powers, and obligations of the Edison Electric Light Company (Limited), and of the Swan United Electric Light Company (Limited), and for other purposes,' is approved, subject to such additions, alterations and variations as Parliament may think fit to make therein."

Mr. E. W. BATT seconded the motion.

Mr. VERITY asked if the chairman could give any reason for the exceedingly low price of the shares. He had, unfortunately, purchased 500 of the shares at two-and-a-quarter. He believed they were manufacturing a number of lamps.

The CHAIRMAN replied that he should be very glad to see the shares standing at a much higher price, but he could not give any explanation whatever.

Mr. VERITY said he did not think that it was from people selling, but the jobbers knocked them down.

A SHAREHOLDER asked whether the Company was really doing any profitable business? He had seen by the report that a large number of lamps had been made, but he failed to discover that any profit whatever had been realised.

The CHAIRMAN replied that Mr. Forbes went into this question when they met to discuss the report. As far as he remembered they made £7,000 clear after paying all expenses in the first thirteen months of their existence, but they had to write that off for depreciation. As far as he knew all business had been transferred to the Edison and Swan, but this Company was still making lamps and selling them fairly well, and they made a profit on the transaction. As far as the foreign business was concerned, they were selling a good many more lamps than they anticipated in the early part of the year.

A SHAREHOLDER said that he was simply astounded at the price of their shares. It appeared to him that, according to the price, there appeared to be no value whatever attached to the concern.

The CHAIRMAN said he supposed they must put it down to the value attached to electric lighting companies' shares generally. This Company had not done much to bring about the depreciation, but electric lighting was still a matter of experiment, and no one could tell what its future would be.

The SHAREHOLDER said that the Company appeared to have been handicapped at the commencement with a huge weight, and they had paid a large sum of money, and whether what they had got in exchange was worth anything or nothing was more than anybody could tell.

In reply to a further question,

The CHAIRMAN said that the passing of the resolution was merely nominal, as the Board hoped to get the thing done in a less expensive manner.

The resolution was then put and carried unanimously.

A vote of thanks to the chairman and directors terminated the proceedings.

## TELEGRAPH CONSTRUCTION AND MAINTENANCE COMPANY (LIMITED).

Report of the directors to be submitted to the members at the twentieth ordinary meeting to be held on Tuesday, the 26th day of February, 1884, at 1 o'clock precisely.

The directors have the pleasure to submit their twentieth annual report to the members. The accounts of the year show a net profit of £93,334 16s after charging the interest on the debentures. To this sum must be added £63,015 5s. 9d. brought forward from last year, making a total of £156,350 1s. 9d. From this amount is deducted the interim dividend of 5 per cent., paid July 24th, 1883, amounting to £22,410, leaving £133,940 1s. 9d. to be dealt with. Of this sum the directors propose to distribute a dividend of £1 16s. per share, absorbing £67,230, being at the rate of 15 per cent., and making, with the amount already paid, a total dividend for the year of £2 8s. per share, free of income-tax, leaving £66,710 1s. 9d. to be carried forward to the next account. The operations carried out during the year 1883 have been as follow:—A cable, 965 miles in length (manufactured in 1882), was laid early in the year between Hong Kong and Shanghai for the Eastern Extension Telegraph Company. A cable, 1,402 miles in length (a large portion of which was manufactured in 1882), has been laid in the Red Sea between Suez and Aden for the Eastern Telegraph Company, and was completed in the month of April. Cables of the total length of 1,369 miles have been manufactured and laid for the Great Northern Telegraph Company of Copenhagen, between Shanghai, in China, and Nagasaki, in Japan, and between the latter port and the Russian Settlement of Vladivostock. These lines were completed in the month of September. The Brazilian Submarine Telegraph Company's cable, between St. Vincent, Cape de Verds, and Pernambuco, Brazil, which was broken in September in the neighbourhood of the Equator in a depth of 1,900 fathoms, has been repaired, a length of about eighty miles of new cable having been spliced in. This cable had been immersed for a period of nearly ten years. A length of 800 miles of cable has been manufactured for the Eastern Extension Telegraph Company, to connect Saigon, in Cochin China, with Tonquin. A length of 847 miles of cable has been manufactured for the Eastern Extension Telegraph Company for the renewal of certain portions of their lines in the China Sea, and between Java and Australia; and for the replacing of the Sunda Strait cable, destroyed by the volcanic eruption of August, 1883. One of the Company's ships is now employed on this work. Various short lengths of cable have been manufactured for other companies during the year. A contract was entered into with the Brazilian Submarine Telegraph Company in the month of October, 1883, for the duplication of their lines between Madeira, St. Vincent, and Pernambuco; and the manufacture of the cables is in progress. The Company's debentures have been renewed on the same terms, for a period of five years, from the 1st January, 1884. The factories at Wharf-road and East Greenwich, and the Company's steamships, are in efficient working order. The "Calabria" made three voyages to Egypt on Government charter during the early part of the year. The retiring directors are Sir Daniel Gooch and Sir Thomas Fairbairn, who, being eligible, offer themselves for re-election. The meeting will have to appoint auditors for the ensuing year.

## THE INDIA RUBBER, GUTTA PERCHA, AND TELEGRAPH WORKS COMPANY (LIMITED).

Directors' report for the year ending December 31, 1883, to be presented at the twentieth ordinary general meeting of the shareholders, to be held at the Cannon-street Hotel, London, on Tuesday, 26th February, 1884, at 12 o'clock noon.

The annexed accounts show the result of the Company's business for the past year.

The net profits amount to £48,390 16s. Adding £36,311 7s. 3d. brought forward, and deducting £15,600 paid in July, there remains a disposable balance of £69,102 3s. 3d.

The directors recommend the distribution of a dividend of £1 per share, amounting to £31,200, and making, with the interim dividend, a total payment for the year of 15 per cent., free of income-tax, carrying forward £37,902 3s. 3d.

The death of Dr. Beattie early this year has deprived the directors of an old and esteemed colleague, whose loss they sincerely regret. The appointment of his successor rests with the directors under the Articles of Association, and they propose to fill the vacancy by the election of Mr. Abraham Scott, who has long been connected with the Company, and is at present one of the auditors.

The general sales compare favourably with those for 1882; but in the first half of the year the cable department was short of work. Important contracts for cables between Spain, the Canary Islands, and Senegal were entered into under subventions from the French and Spanish Governments; but, as these are still in course of completion, no credit has been taken for any profit, and the work merely stands in the accounts at cost.

Less progress than the directors intended has been made with the Workmen's Hall, but the matter is not being neglected, though other building operations at Silvertown have interfered with it. The new works mentioned in the last report as being in progress at Silvertown and Persan-Beaumont are nearly completed, and the railway now runs into the factory yard at the latter place.

The Company's Bill in Parliament, referred to in the circular of the 12th of November, will be considered at an extraordinary general meeting, notice of which is given with this report.

## NATIONAL TELEPHONE COMPANY (LIMITED).

An extraordinary general meeting of the above Company was held on the 20th instant at the offices, Queen Victoria-street, Colonel R. Raynsford Jackson in the chair, when the following resolution was passed, on the motion of the Chairman, seconded by Mr. W. Garnett:—"That the directors are hereby authorised to borrow the sum of £75,000 for the purposes of the Company, and to secure the same by the issue of mortgage debenture bonds upon such terms and conditions, and charged upon all or such portion of the undertaking of the Company as the directors may think fit."

## NOTES.

CABLE REPAIRED.—The cable between St. Vincent and Barbadoes is repaired.

CABLE INTERRUPTED.—The cable between Lima and Mollendo is interrupted.

HAIPHONG AND TONQUIN.—Telegraphic communication has been established with Thuan in Annam and with Haiphong in Tonquin.

BRAZILIAN SUBMARINE TELEGRAPH COMPANY.—The traffic receipts of this company for the week ended 22nd February, amounted to £3,514.

THE JABLOCHKOFF COMPANY.—Mr. Justice Pearson has made a supervision order in the matter of the voluntary winding up of this company.

PERSONAL.—We understand that the address of Mr. Radcliffe-Ward remains for the present 110, Cannon-street, E.C., as consulting electrical engineer.

EARTHQUAKE IN BRITISH NORTH AMERICA.—The latest information from this quarter states that shocks of earthquake have been felt in New Brunswick.

THE MAGAZINES.—In the March number of *Time* there will be a portrait and memoir of Mr. Frank Ives Scudamore, whose death we recorded in a recent issue.

TELEGRAPHING MONEY ORDERS.—We see it stated that the system of granting telegraphic money orders is soon to be brought into operation throughout India.

ELECTRIC RAILWAY AT BRIGHTON.—The extension of Volk's electric railway at Brighton is progressing satisfactorily. The railway is expected to be opened before Easter.

SOCIETY OF ARTS.—On Thursday night last Professor Silvanus P. Thompson was to read a paper before this society on "Recent Progress in Dynamo-Electric Machinery."

THE NEW ATLANTIC CABLE.—It is stated that Waterville, near the other cable station at Valentia, Ireland, has been selected as the station for the Bennett-Mackay cable.

THE TELEPHONE AND THE HOUSE OF COMMONS.—Direct telephonic communication has been successfully established between the Carlton Club and the House of Commons.

EARTHQUAKES IN TURKEY.—A telegram from Constantinople says:—"Shocks of earthquake continue to be felt at various places in Asia Minor, particularly at Moosh. No damage has been caused."

NEW TELEGRAPH STATION IN CHINA.—The Great Northern Telegraph Company inform us that a telegraph station has been opened at Wuhu (China). The rate to Wuhu from all stations in the United Kingdom is 9s. 8d. per word.

WESTERN AND BRAZILIAN TELEGRAPH COMPANY.—The traffic receipts of this company for the week ending February 22nd, were £2,720, after deducting the "fifth" of the gross receipts payable to the London Platino-Brazilian Telegraph Company.

SHOREDITCH VESTRY AND PROVISIONAL ORDERS.—This vestry are of opinion that no extension of time should be granted the electric lighting company which has applied for a provisional order for their district, and have written to the Board of Trade to this effect.

SS. "RETRIEVER."—This cable ship, belonging to the Eastern Telegraph Company, did valuable service in the Red Sea on Saturday last. The transport "Mansourah" had run on to a reef, and was in a critical position, when the Retriever managed to get her off.

WEST INDIA AND PANAMA TELEGRAPH COMPANY.—The estimated traffic receipts of this Company for the half-month ended the 15th February are £2,967, as compared with £3,368 in the corresponding period of 1883. The November receipts, estimated at £4,563, realised £4,671.

THE EDISON-SWAN AND SWAN UNITED COMPANIES.—The Edison and Swan United Electric Light Company having made a call of 10s. per share, the Swan United Electric Light Company has made a similar call to enable them to meet this contribution, and also to provide funds for their foreign business.

ELECTRIC LIGHTING FOR NOTTINGHAM.—We understand that the Town Council of the borough of Nottingham are prepared to open negotiations with any company willing to light particular districts of the borough by electricity. All communications to be addressed to the town clerk, Municipal Offices, Nottingham.

ELECTRICAL CONDUCTORS.—The Institution of Civil Engineers have published Mr. Preece's paper "On Electrical Conductors" in pamphlet form, with an abstract of the discussion, which, by the way, occupies 47 pages of the publication. Electricians will find both paper and discussion good reading and handy for reference.

EARTHQUAKES IN TASMANIA.—The *Colonies and India* says that earthquakes continued to be felt in the north of Tasmania during December and part of January. At St. Mary's there were two or three shocks every day, and exceptionally severe shocks occurred on January 1 and 4, accompanied by loud noises, which lasted a long time.

THE TELEPHONE IN BARCELONA.—A correspondent writes as follows:—The Barcelona Municipality intends to establish micro-telephonic communication with its different departments, fire-engine stations, &c. Proposals will be received at the "Casa Consistorial" by noon on the 26th March for supplying the necessary material for 16 lines. The maximum limit fixed is 12,602 pesetas.

A NEW CABLE FOR TELEPHONIC PURPOSES.—Herr Madsen, the director of the Danish Telegraph Company, has invented a new kind of telephone cable, which will include 25 telephone wires, and greatly, it is said, minimise the danger of overhead wires. The cable is being manufactured by Messrs. Felten and Guillaume, of Mülheim-on-the-Rhine. The Madsen cable is said to bear a span of 70 metres.

THE LAST PART.—It is stated that the "Great Eastern" has been purchased by a firm who intend to use her as a coal hulk at Gibraltar. Perhaps it is better that she should be made use of than that her bones should rot in Milford Harbour. But what a come down for a vessel which laid the first Atlantic cable. She has in her lifetime played many parts, and, after all, perhaps the last will not be the least useful.

COMMISSIONERS OF SEWERS.—At the last meeting of the Commissioners of Sewers a vote of thanks was unanimously accorded to Mr. E. J. Stoneham, Chairman of the Electric Lighting Committee which the commissioners have just dissolved. As was stated by a gentleman at the meeting, Mr. Stoneham's committee have paved the way for the Streets Committee, who now look after electric lighting.

TELEGRAPHIC COMMUNICATION WITH LUNDY ISLAND.—A large body of men are now engaged on the land line in connection with the above undertaking. The cable will be landed at Hartland, N. Devon, and communication is expected to be established in ten days. The land line is of silicium bronze wire, No. 15, B.W.G., and supplied by the Phosphor Bronze Com-

Digitized by Google

pany, London, Mr. John Legg, of Swansea, being the contractor.

THE TELEPHONE AT A DYNAMITE FACTORY.—The various widely isolated magazines and nitro-glycerine sheds of Nobel's Explosives Company in Ayrshire, which are buried amongst sandhills near the sea beach, have been grouped together by telephonic circuits on the exchange principle, and placed in direct communication with the manager's office. Messrs. Tasker Sons and Co., of Sheffield, carried out the work, and used the Johnson-Bell combination telephone.

THE "FARADAY."—The "Faraday," with the first portion of the Bennett-Mackay cable on board, broke down in the Atlantic on February 10, and was compelled to put back to Weymouth for repairs, where she arrived last week. The damage sustained consisted of the loss of the port propeller, and it was proposed that the vessel should be brought back to London for the necessary repairs. This is the second misfortune sustained by Messrs. Siemens in connection with the New Atlantic cable.

BOOKS RECEIVED.—"The Law and Practice of Patents," by Clement Higgins. Published by William Clowes and Sons, 27, Fleet-street, E.C.—"The Patents, Designs, and Trade Marks Act, Rules, &c., 1883, with a Practical Treatise Thereon," by Bristow Hunt. Published by Waterlow and Sons, London-wall, E.C. — "The Watch and Clockmakers' Handbook, Dictionary, and Guide," by F. J. Britten. Published by Kent and Co., Paternoster-row, E.C., and Spon, New York.

A CHURCH STRUCK BY LIGHTNING.—Early on Thursday morning, the 21st ult., a terrific thunderstorm raged at Kidwelly, Carmarthenshire. The lightning struck the church spire, which is 180ft. high, and hurled 30ft. of it down, some of the stones being thrown a great distance. Some of the stones fell through the roofs of adjacent houses, the inmates in bed having narrow escapes. A further portion of the spire is dangerous, and is being pulled down by the aid of coast-guardsmen. The spire was one of the highest in South Wales.

OVERHEAD TELEGRAPH WIRES.—It is said that the Government has so far yielded to the pressure that has been put upon it by the metropolitan vestries in the matter of overhead telegraph and telephone wires, that it has arranged that a conference of the Postmaster-General with representatives of other Government departments concerned, and of the various private companies interested, shall take place for the purpose of discussing the necessity for the introduction into Parliament of a measure giving powers of control over such wires to local authorities through whose district they pass. This rumour has, however, been contradicted on good authority.

FOSSILS.—A writer in a daily paper says, speaking of a recent archæological discovery :—"In no strata, however deep we dig, do we come on fossil telephones, remains of hammerless choke bore guns, apparatus for electric lighting, and the other relics which quaternary culture should have bequeathed to us." We think that if the writer will take the trouble to dig into the piles of patents in our Patent Office, he will find plenty of fossil telephones, fossil dynamos, and fossil electrical apparatus of all kinds. Why, fossils of this sort are being patented and re-patented every day and all day. The pity is that they are not always identified and promptly labelled as such.

TELEGRAPHIC CONTEST.—The speed of sending in the telegraphic contest described in a note in our last issue has now been made public. It appears that Mr. J. Chapman, of the London Stock Exchange, who was adjudged the winner, took 7m. 50⅗sec. to send his 250 words; Mr. J. Dennett, of the Central Telegraph Office, who came second, sent the same quantity in 7m. 30⅘sec., whilst the time occupied by Mr. A. Brooker, of the same office, who was third, was 7m. 48sec. Morse instruments were used, and of course accuracy as well as despatch were considered, hence Mr. Chapman, though not the fastest sender of the three winners, was the most accurate.

THE ELECTRIC LIGHT AT SUAKIM.—In the House of Commons this week Lord H. Lennox asked the Secretary to the Admiralty whether any of Her Majesty's ships on the East Indian Station were provided with the electric light; and, if not, whether prompt steps would be taken to remedy so serious a defect?—Mr. Campbell-Bannerman replied that of the ships on the East Indian Station the "Euryalus" alone is of the class which is now usually fitted with the electric light, and she was not so fitted when she left England in August, 1878. The "Hecla," now in the Red Sea, carried the electric light, and was at the disposal of the admiral for any purpose requiring its use. He had not heard that it had been used.

OVERLHEAD TELEGRAPH WIRES IN WANDSWORTH. — At the last meeting of the Wandsworth District Board of Works, the clerk (Mr. Corsellis) reported that in the action between the General Post Office and the Wandsworth Board, the magistrate (Mr. Paget) had decided in favour of overhead wires, and against the Board in every case except one, *i.e.*, the line from Park-hill and Loat's-road, Clapham. He had, however, ordered all the posts to be of iron, and the wire of copper. Mr. Morton moved that the Board appeal against the decision, and the motion was carried unanimously. We have referred to this case during its progress in previous notes. We certainly think the matter is worth bringing before a higher tribunal.

ELECTRIC LIGHTING IN IRONWORKS.—The New British Iron Company have recently lighted their Corngreaves Works, near Birmingham, by electricity. The Maxim-Weston Company has carried out the installation, which consists of eleven Weston arc lamps of 1,400 candle-power each, supplied with current from a Weston dynamo. The dynamo is driven at a maximum speed of 1,050 revolutions by one of Messrs. Tangye's vertical engines of 10 nominal horse-power, the power being transmitted through a short length of shafting, by means of ordinary leather belts running on special wrought-iron pulleys, supplied by Messrs. Hudswell Clarke and Co., of Leeds.

LIGHTNING AND COLLIERIES.—At the last meeting of the North of England Institute of Mining and Mechanical Engineers, held in Newcastle-on-Tyne, a few days since, a paper by Mr. Henry White, giving an account of lightning which descended the pit at West Thornley Colliery, was read. The paper contained a description of an occurrence that took place at this colliery (which had been struck on more than one occasion previously) on December 11, 1883. The steam boiler chimney, 46ft. high, was struck, and during the storm the lightning descended the shaft, apparently along the rapper rope, where it was seen to glance from the rapper handle at the bottom of the pit to some 5in. steam pipes which were uncovered about 3ft. off.

ELECTRIC LIGHTING FOR DANCES.—Messrs. Laing, Wharton, and Down, in conjunction with Mr. G. V. C. Holmes, have recently carried out several temporary installations of Swan lamps, and Holmes' primary battery, for dances, evening parties, &c. Amongst others was a ball last week at Kensington, at the house of Mr. Henn Collins, Q.C., and also a dance given by Mrs. Wharton, at Old Charlton. The lamps used in all cases have been the low resistance ten candle-power Swan lamps, which, when worked over power, afford a beautiful light, and in every case have given complete satisfaction, not only as regards the actual lighting, but also to the ladies, who at first very much feared the electric light for their complexions and dresses,

Digitized by Google

but eventually were unanimous in thinking that it was most becoming.

INTERCEPTING TELEGRAMS.—The *Invalide Russe* reports the invention by a Russian officer of Sappers, Lieutenant Krudinow, of a portable apparatus for intercepting telegraphic and telephonic messages in war time. The apparatus is a small square box weighing a little over two kilogrammes. It contains mechanisms for transcribing a telegram or making a telephonic message audible. At the top of the box is a small battery for returning the enemy false messages. For sending ordinary telegrams the apparatus should be in the hands of a telegraphist. It is enough to send a man within the enemy's lines, who would cut the telegraph wires and connect them with the apparatus, setting the mechanism going which unrolls the strip of paper. The telegraph then automatically transcribes the message on the paper, which need only be sent to the nearest staff office to be deciphered. The apparatus has already been tried and found practicable.

ELECTRIC LIGHTING FOR WOLVERHAMPTON.—It is understood, says a provincial contemporary, that the General Purposes Committee of the Wolverhampton Town Council have opposed the application of the South Staffordshire Electric Lighting Company to the Board of Trade to extend the period of appropriation and deposit of capital of the Wolverhampton Electric Lighting Order, granted last year, for twelve instead of six months from the date of confirmation. The cause of such opposition is not yet apparent, but it is understood that the committee occupy a somewhat unique position, since similar applications to the Board of Trade by other of the electric lighting companies in this district have not been opposed by the respective town councils concerned; nor have the South Staffordshire Company themselves met with such objection from other town councils in the district. The effect, so far, of the Wolverhampton opposition has been that the Board of Trade announce to the company that they have decided not to approve of an extension of time.

HIS FATHER'S SON.—Mr. Francis Scudamore, who is at present in the Soudan acting as special correspondent for the *Melbourne Argus*, is thus referred to by the *Daily News* correspondent in its issue of the 27th ult., describing the overthrow of Baker Pasha's army at Teb:—"The bravery of a handful of Englishmen was the only redeeming feature of this frightful disaster. Here is a case in point. Lieutenant Maxwell and Mr. Francis Scudamore, riding onwards to the front, overtook Lieutenant Barton, who, having lost his horse, was running on foot. Lieutenant Barton was quite worn out. Maxwell invited him to get up behind him, which he did; but the horse, besides being wounded, was scarcely up to the weight of his brace of riders—and Barton alone weighs some seventeen or eighteen stone. The horse came to a dead stop, and the Arabs were coming. Scudamore then gave his own horse to Mr. Barton, remarking, "You are done up; I am light, and can run." Mr. Barton galloped off, and Mr. Scudamore, seizing Maxwell's stirrup, ran for awhile. But this experiment failed also, and the runner got up behind Mr. Maxwell, the former, with his arms round his friend's waist, holding the reins and "steering," while the latter looked after the revolver and rifle, and in this amusing style of marching order the couple reached the fort. Mr. Scudamore is the son of the well-known ex-official of St. Martin's-le-Grand."

ELECTRO-CHEMISTRY.—According to Faraday's law and the experiments of M. Becquerel, a given current of electricity, traversing a series of salts capable of being electrolysed during a given time, separates at the negative pole weights of the different metals proportional to their equivalents; that is to say, that 107·9gr. of silver being precipitated, the same current will precipitate in the same time 103·5gr. of lead. It will also separate 39·1gr. of potassium and 68·5gr. of barium (as these latter metals decompose water they do not exist free, but are found as a free base round the pole). These different weights are, I repeat, proportional to the equivalents, that is, according to the classical definition, to the relative weights according to which the metals may be substituted the one for the other. In order that they should be proportional to the atomic weights we ought to obtain in the same time as 107·9gr. of silver 207gr. of lead, that is double the weight actually precipitated; in the same time that it takes to obtain 39·1gr. of potassium we ought to obtain 137gr. of barium, which is not the case in the same way with the electro-negative elements. If we electrolyse in a similar circuit the chloride and oxyde of a similar metal, the weights of chlorine and oxygen set free in the same period are proportional to 35gr., 5gr. for chlorine, and 8gr. for oxygen, that is, to the equivalents. If they were proportional to the atomic weights, we ought to obtain for 35·5gr. of chlorine, 16gr. of oxygen, which is not the case. Without entering into any discussion on the valency of bodies, the idea of which is anterior to the new atomic notation, since it is the result of the discovery of polybasic acids by Graham in 1835, of polyatomic alcohols by myself in 1854, and of glycol two years after by my learned friend, M. Wurtz—without entering, I say, into any such discussion, I confine myself to testifying that Faraday's law is more simply expressed, as a rule, by means of equivalents than by means of atomic weights, both as concerns electro-positive and electro-negative elements.—M. Berthelot, in the *Comptes Rendus*.

ELECTRICITY AND THE WORKING CLASSES.—An attempt that has met with considerable success has lately been made at Poplar to induce the industrial classes to attend lectures on various subjects, and on Monday last one of these lectures was delivered at Cotton-street Chapel, Poplar, by Mr. A. Reckenzaun, the subject being "Electricity, how Produced and Applied to Lighting and Motive Power," with illustrations. The Rev. B. Preece, the pastor of the chapel, presided, and the building was crowded by an audience composed almost entirely of the class of persons for whom the lecture was intended. A more attentive and appreciative audience could not have been desired. Mr. Reckenzaun's lecture was of a most interesting character; he gave a brief history, indicating the various discoveries which led up to the present position of the science, and also described the various appliances, and explained the fundamental rules and laws which govern it. The experiments and illustrations, which, as may be supposed, found great favour with the audience, were of a most effective character. The apparatus consisted of a number of 20-candle Swan lamps, which decorated the platform, and which were fed by 25 Faure-Sellon-Volckmar accumulators, each of which weighed 28lb. The cells also fed a 1½ horse-power motor, driving a screw propeller. This motor was especially designed by Mr. Reckenzaun for propelling small boats; it weighs only 106lb., and gives a high efficiency. Another interesting feature in the proceedings was the exhibition of a novel arc lamp, devised by Messrs. Thornton and Romanze, of the Electrical Power Storage Company, which burned very steadily. Another arc lamp for photographic purposes was shown, having an arrangement by which the focus can be regulated. Numerous experiments were made to show how the electric current can be produced by wire coils moving in a magnetic field, and a number of beautiful diagrams illustrated the Gramme ring, Ohm's law, the accumulator, electric lamps, electric boats, &c. A cordial and hearty vote of thanks was accorded to the lecturer, and the meeting broke up, but it was some time

Digitized by Google

before the chapel was cleared, for a large number remained to more closely examine the apparatus and diagrams.

SS. "VALETTA."—We recently announced that this ship had been launched, and was to be fitted up on the incandescent system by the Edison and Swan United Electric Light Company. A few details of this installation will no doubt be of interest. The dynamos used are two Edison L machines, which have been altered to run at a slower speed—rather over 500 revolutions per minute—and sustain a somewhat larger number of lights than the normal number by the strengthening of the magnetic field and certain other modifications. They are each capable of sustaining 150 incandescent lamps of 16 candle-power actual. It is only for a short time during the evening, when all the lights on board, amounting to about 240, are required at once, that it is necessary to run both dynamos at the same time. They are driven by a pair of vertical engines, running at 270 revolutions per minute, made by Messrs. J. and H. Gwynne, of Hammersmith, and are geared by means of an endless cotton rope, which is wound ten times round pulleys provided with ten U grooves, the last turn being guided back to the proper groove by a pair of small guide pulleys. This arrangement works exceedingly smoothly, and is free from liability to break down, besides throwing very little strain on the shafts. The dynamos are placed on slides, and by means of screws can be moved forward to compensate for stretching of the rope. The saloon is fitted with four rows of handsome gilded two-light pendants placed over the tables. The state rooms are lighted from lanterns let into the bulkhead, which also throw a light into the alley-ways, and are made to carry a candle as well as an incandescent lamp. The engine room, stoke hole, and the various stores, officers' quarters, and forecastle, &c., are all supplied with substantial fittings, and are well lighted throughout. The wires are, as usual in all installations made by the Edison and Swan Company on board ship, run in wood cases securely separating the leads and returns, all main and branch circuits being fitted with fusible plugs. Where necessary, individual lamps are controlled by switches on the sockets, and a substantial switch-board is placed in the dynamo room, to which are led the six circuits into which the wiring is divided. These are so arranged that, by changing the plugs, any circuit may be connected up to either dynamo. During the stay of the "Valetta" in London, prior to her departure on her first voyage to Australia, the light was frequently exhibited to the visitors whom the P. and O. Company invited on board. The entire absence of perceptible noise from the machinery was noticed as being an important feature of this installation—one of the most recent and best examples of the application of the electric light to steam ships.

INCREASED TELEPHONIC FACILITIES.—On Friday, the 22nd inst., Mr. Fawcett received another deputation, who urged upon him the necessity for a quicker mail service between England and Ireland, and increased telephonic facilities. This time the deputation consisted of members of the Associated Chambers of Commerce. Mr. Norwood, M.P., having introduced the deputation, a resolution of the chambers was brought before the right hon. gentleman, recommending a reduction of the present excessive rates, and urging that licenses should be granted to responsible persons and companies on such terms as would enable them to carry on exchanges at the least possible charge to the public.—Mr. Wolff (Hull) in supporting this resolution, contended that telephonic communication should be thrown open to public competition. The deputation also made representations as to the advisability of a reduction in rates for foreign telegrams, especially in the case of Russia and Sweden, and in favour of the establishment of a telegraphic union.—Mr. Fawcett, in reply, said with regard to the policy of the Post Office in reference to telephonic communication, he might say that there was no jealousy towards the telephonic companies. If any town thought that they could be supplied better with regard to telephonic communication by private enterprise than they could be by the Post Office, he could only say that as far as he was concerned he would be delighted for them to have telephonic communication supplied through private enterprise. The deputation thought the Post Office ought not to make a charge to the telephonic companies. The position of the case was this—that Parliament had decided to spend a very large sum of public money, ten millions sterling, in the purchase of a telegraphic monopoly. Then, it having been decided that telephony was an infringement of this Government monopoly, he fixed a royalty of 10 per cent. for the telephonic companies to pay, and that was not an unreasonable sum. With regard to the Post Office telephonic charges, they did not charge more than they ought, looking at it as an enterprise of a purely commercial character. The whole question was in its infancy, and if, as time went on, it should be found that the charge could be reduced, having due regard to the revenue, it should be done. As to the charges for private telegraph wires, that was a matter which was absolutely in the hands of the public themselves. The Post Office had no monopoly, and there was nothing to prevent any gentleman who wanted to be supplied with what was called private wire going to any firm for it, if he thought that he could obtain it cheaper and better than that supplied by the Post Office. With regard to the telegraphic charges in foreign countries, there had been considerable reductions in the telegraphic rates, and the department would be glad to have them still further reduced. They had no other object to perform, except while giving proper protection to the revenue to make the Post Office useful to the community, and there was no part of its work which it was more important for it zealously to discharge than, as far as possible, to make itself useful to the general commercial association which the deputation represented.

THE UNITED TELEPHONE COMPANIES' BILL.—Mr. Charles Mossop, chairman of the Electric Lighting Committee of the Chelsea Vestry, and Mr. G. H. Stayton, surveyor to the vestry, have drawn up a very exhaustive and able report on the Bill which the United Telephone Company are endeavouring to promote with reference to overhead wires. This report was adopted by the vestry on Tuesday last. We regret that our space will only permit us to briefly refer to the chief points touched on by the reporters, though we may have more to say on the subject later on. The report suggests that as nearly all the metropolitan vestries and boards of works will be affected by this Bill that it would be to the common advantage to concentrate their views, and to request one central representative body to act in obtaining its amendment, or, if necessary, to oppose the Bill. The vestry have communicated with the Metropolitan Board of Works on this subject, and have been informed that the Board intend to petition against the Bill, on the ground that the powers sought by it are greater than should be conferred on any commercial company. Should the Bill be passed the Board will ask that telephone wires shall in no case be erected or laid without its consent be first obtained. The Board will also petition that all works which may be done by the telephone companies shall be required to be done to the satisfaction of the vestries and district boards. The report then goes on to consider the overhead wire question from the vestry's point of view. The following extract will show what their opinion is:—"Coming to the vexed question of overhead wires, on which

Digitized by Google

the allegation in the preamble has already been quoted, it is needless to remind your committee that the vestry set its face against their introduction into the parish for the purposes of electric lighting, and that public opinion is strongly opposed to such a means of conveying electricity. At the risk, however, of being considered bold, we venture to submit that the popular judgment is unsound. In agreeing on this conclusion, after calmly and dispassionately viewing the arguments on both sides, we have had regard to the value of the telephone to the commercial world, and to the power which the Bill provides for the examination and testing of the wires. However the Bill may in some respects limit the power of local authorities it enables them to impose such prohibitive conditions as would either partially or wholly debar the parish from the advantage which telephonic communication affords, as the scale of subscription must of necessity be regulated according to the cost of construction and maintenance. We gather that the cost per mile of wires laid underground is £350, whereas overhead wires can be fixed at £10 per mile, a contrast to which, as reasonable and business men, your committee will give due heed. Bearing in mind that the public are impressed much more by the occasional dangers or risks incurred from wires being suspended without proper supervision, or left to decay, or unowned, than by the immense advantages which attend the use of efficient wires, and that this Bill makes certain provisions to remedy the defects referred to, we venture to assert that overhead wires might, with proper supervision, be made safe, and with periodical testings efficiently maintained, under which circumstances local authorities might (subject to certain exceptions and to rigid conditions) give their consent to the limited use of overhead wires, rather than to insist on the use of underground wires only, at a thirty-fold increase of the outlay, and consequent addition of cost to the user." We make no comment on this matter now, though we hope to do so in another issue. We may remark that on the question of overhead wires we are not quite at one with the vestry.

Gas Engines.—Professor Fleeming Jenkin delivered a lecture on "Gas and Caloric Engines" at the Institution of Civil Engineers on the 21st February (the fourth of a course of six lectures on "Heat in its Mechanical Applications"), of which the following is an abstract so far as gas engines are concerned:—The engine designed by Otto, and improved by Crossley, was described as one typical example, and the other chosen was that made by Thomson and Sterne according to Mr. Dugald Clerk's plan. The following points were named as those of chief interest:—The limitation to the higher and lower limits of temperature; the rate at which combustion proceeded inside the cylinder; whether dissociation was a sure course of the limit to the higher temperature; the loss of heat by the cooling of the walls of the cylinder, and the loss of heat in the residual products rejected. Experiments specially made by Messrs. Crossley were described, showing that a change in speed with a constant charge had caused an alteration in the maximum pressure and maximum temperature; but that this change did not extend between wide limits. A change in the richness of the mixture produced a much greater change in pressure and temperature. A diagram was shown in which the pressure was almost uniform throughout the stroke, and another showing the modification produced in the indicator-diagram when the charge introduced was not allowed to mix with the residual products. All these diagrams tended to prove that gradual combustion certainly took place in these engines, and that the rate of combustion was under control. A series of very interesting diagrams, illustrating experiments made by Mr. Clerk, was then explained, the rate of combustion in different mixtures of gas and air, and of hydrogen and air, being exhibited by a continuous curve. These experiments established beyond a doubt that the rate of combustion varied in proportion to the richness of the mixture, and that this rate was, in the poorer mixtures, such that a considerable portion of the stroke would be completed before the combustion was complete. In fact, Mr. Clerk's experiments and those of Messrs. Crossley nearly agreed, although these makers might differ in their explanation of the cause. The experiments further showed that whether dissociation acted as a limit to the temperature or not, practically the mean temperature of the contents of the cylinder in gas engines at the beginning of the stroke seldom rose above 1,550° Centigrade. The experiments of the makers further agreed in this:—That the loss by conduction through the walls of the cylinder was a little over 50 per cent., and that at the moment when the highest pressure was attained not much more than one half of the total heat was developed, the rest being developed throughout the stroke. The lecturer pointed out that the true condition of the burning gases was one which it was extremely difficult to analyse or follow; that within the cylinder there must be an extremely hot kernel at a temperature greatly above the mean; that at the outside there must be a layer little above 150° Centigrade, and between these limits layers at all temperatures; that part of the gases must expand receiving heat, and part give it up. But it was interesting to find that the practical result of these complicated actions did not differ widely from the adiabatic curve, although, in point of fact, one-half of the heat was being given up by conduction. Passing from these theoretical considerations to the practical results, the lecturer found a similar agreement. Both makers produced engines giving one indicated horse-power for 20 cubic feet of gas. This result corresponded to one-third or one-fourth of the consumption recorded for the early gas-engines made by Lenoir. Moreover, they showed that from 16 to 21 per cent. of the whole of the heat generated was actually converted into indicated horse-power, notwithstanding the enormous waste of one-half by conduction across the walls. In absolute heat efficiency, therefore, the gas-engine was already 100 per cent. better than the steam-engine. When, however, what might be termed the relative efficiency was compared, that was to say, the relation between the theoretical achievement which was possible, and the actual achievement, the steam-engine would be found nearly to have reached the limit of what was possible or probable, whereas the gas-engine was very imperfect, and therefore gave hopes of great improvement. Taking the range of temperatures as the highest and lowest used in a gas-engine, the ideal efficiency might be spoken of as 77 per cent., but no real gas-engine could reach this figure, because the heat was not wholly given at the higher, nor wholly rejected at the lower temperature. If the indicator-diagram were treated as bounded by two adiabatic curves and two vertical lines, the theoretical efficiency of the gas-engine with the temperature described would be about 48 per cent., and one-half of this had been attained, the other half being accounted for by the cooling of the walls. The lecturer then passed on to consider what possible means might be suggested for improvement, and divided these into two classes—those in which it was intended to lower the practical temperature of rejection, and those in which it was intended to diminish the loss by cooling. As regarded the first of these—increasing the pressure of compression produced good results by increasing the expansion; but the advance to be made in this direction was not expected to be great, as the pressures used were already large.

## ELECTRO-CHEMISTRY.

### INORGANIC.

BY DR. G. GORE, F.R.S.

(CONTINUED FROM PAGE 345.)

**Electrolysis of Nitrate of Palladium.**—A solution of this salt is said to be a good conductor, but apt to yield the metal in the form of a black powder. I electrolysed strong nitric acid, by means of a current from fifty Smee cells, with a palladium anode and platinum cathode. Copious conduction, and rapid decomposition of the acid, with abundant evolution of red fumes, took place. Much gas was set free from the anode, but none from the cathode until after a short time. The anode was not at first visibly corroded, but after half an hour's action the palladium slowly dissolved, forming a red liquid. No metallic deposit formed upon the cathode.

Nitrate of palladium dissolved in water and acidified with a little nitric acid, deposited upon the cathode a bronze coloured coating, which by prolonged action became darker, and then black, and was easily soluble in nitric acid. Some reddish oxide was formed upon the anode. Alkaline solutions behaved similarly, except that the action was slower, and the deposited metal more adhesive (Schucht. Berg ünd Hüttenmannische Zeitung, *Chem. News*, Vol. XLI., p. 280).

**Formation of Fluoride of Palladium.**—$PdF_4$. Molecular weight = 182·5. I electrolysed thirty per cent. pure aqueous hydrofluoric acid, with a sheet palladium anode, in a large platinum vessel as the cathode, by means of a current from six Smee elements. Free conduction occurred, and much gas was evolved from each electrode, and there was a strong odour of ozone. A dark, red-brown thin coating formed upon the palladium, but did not dissolve during fifteen hours' electrolysis. The liquid was filled with minute floating particles of palladium, caused by the reducing action of the hydrogen from the cathode. After six days' continuous action the anode was greatly corroded.

I also electrolysed the pure anhydrous acid in a chilled state, in the same vessel, with a thick palladium anode and the same current, and sometimes with a current from thirty cells. The process was difficult and very dangerous, and notwithstanding the low temperature, and that the vessel was closely covered by a lid of paraffin, the acid volatilised rapidly and fumed greatly, partly in consequence of the escaping hydrogen and the heat of conduction resistance. The coldness of the vessel and the intense attraction of the acid for moisture caused water to condense upon the lid of the vessel, and rendered it difficult to preserve the acid in the anhydrous state. The lid was therefore made to overhang the edge of the cup, and was also covered by a layer of cotton wool. With a current from twenty cells the conduction was copious. The anode quickly became coated with a thick, dark, red-brown, brittle crust, which was of a redder colour on the side next the anode, and did not perceptibly impede the passage of the current. This crust was scraped off at intervals of about one hour into a platinum dish standing upon a slab of iron heated to about 350° F., and at once transferred to a closed platinum bottle. After eleven hours' action, the acid was still colourless, as if the crust upon the anode was perfectly insoluble. Some black powder, which proved to be metallic palladium, was, however, found upon the cathode, and indicated that some palladium had dissolved and been reduced. The crust also on the side towards the anode was nearly black when dry, and showed signs of metallic particles when pressed between smooth surfaces of agate, indicating some reduction by the diffused hydrogen.

In some other experiments the hydrogen was more perfectly excluded from touching the anode. The platinum cup was $2\frac{3}{4}$ inches wide and $3\frac{1}{4}$ inches deep, divided into two equal parts by a well-fitting vertical plate of paraffin, which extended to within half an inch of the bottom. The palladium anode and platinum cathode were each about four inches long, and one inch wide, and firmly fixed in slits in the two halves of the paraffin lid. With $5\frac{1}{2}$ ounces of the perfectly anhydrous acid, and a current from twelve one-pint Grove cells, the conduction was copious, and in five minutes the immersed part of the anode had acquired a deep brown colour. The electrolysis was continued during five hours, the anode being taken out and scraped each half hour, and the crust preserved in a platinum bottle. The crust was hard, and sparks were sometimes caused by particles of it being decomposed by the heat of friction in removing it. A hissing sound was heard during the whole of the electrolysis, but the density of the fumes prevented any effervescence being seen. 10·46 grains of black powder were found upon the cathode and adjacent parts of the vessel and partition, and yielded 10·11 grains of metallic palladium; this indicated some small degree of solubility of the crust, and the great necessity of excluding hydrogen from touching the anode. The anode had lost 37·90 grains in weight, and 54·13 grains of the dry brown crust was obtained. After deducting the 10·11 grains of palladium found in the liquid, the remaining quantity of corroded metal would form only 47·62 grains of tetrafluoride; the crust therefore contained in addition probably some hydrofluoric acid.

I also found that a palladium anode was very rapidly corroded by the passage of a current from six Grove elements through pure potassic fluoride in a state of fusion. Finely divided palladium was found in the saline residue.

**Electrolysis of Chloride and Iodide of Palladium.**—I electrolysed concentrated, also dilute hydrochloric acid, by a current from 50 Smee cells with a palladium anode and a platinum cathode. Action was instant and rapid, hydrogen was copiously evolved from the cathode and chlorine from the anode, and the anode dissolved, forming a blood-red liquid, and a black deposit of palladium soon formed upon the cathode.

M. A. Bertrand recommends a perfectly neutral solution of the double chlorides of palladium and ammonium, with or without the use of a separate current, for the separation of this metal (*Chem. News*, Vol. XXIV., p. 227). It is stated that with a separate current from two or three cells and a palladium anode, the current is somewhat impeded in this solution by a bright golden yellow coating forming upon the anode. Iodide of palladium dissolved in a solution of potassic iodide is an unsatisfactory one for yielding reguline metal.

**Electrolysis of Cyanide of Palladium.**—$Pd.\ Cy_2$. Molecular weight = 158·5. A solution of the double cyanide of palladium and potassium, containing free potassic cyanide, is said to yield by the separate current process thick deposits of the metal in a reguline state. The liquid holds in solution a large quantity of the metal, and may be prepared either by the usual chemical means—*i.e.*, by dissolving cyanide of palladium in a solution of potassic cyanide, or by the battery process. A less satisfactory mixture may also be made by dissolving chloride of palladium in a solution of the alkaline cyanide. A solution for depositing palladium is prepared as follows:—Cyanide of palladium is mixed with 7 per cent. of ferro cyanide of potassium, 3 per cent. of caustic potash, and 60 per cent. of water, and the mixture boiled during half an hour, the lost water being replaced. (Frantz, *Chem. Centr.* 1876, p. 592.)

**Separation of Platinum.**—Pt. Atomic weight = 197. A tetrad cation. Nearly all electrolytic operations with platinum are performed with a solution of the tetrachloride, or with hydrochloric acid, because with the exception of anhydrous hydrofluoric acid, a solution which yields chlorine at the anode, is nearly the only one in which metallic platinum will dissolve; even a solution of potassic cyanide with a strong current corrodes an anode of platinum but sparingly. Nearly all the ordinary metals become coated with platinum in its solutions by the process of simple immersion, and it may be separated by each of the methods of electrolysis.

Magnesium in a solution of platinic chloride evolves hydrogen, and after about twenty hours deposits a black powder of metallic platinum. On leaving it in contact with water, a brown hydrate of platinum is formed (S. Kern, *Jour. Chem. Soc.*, 1876, Part I., p. 684). Sodium amalgam decomposes a concentrated solution of platinic chloride, also one of chloroplatinate of ammonium, and forms in each case an amalgam. According to Joule, the electro deposition of plati-

Digitized by Google

num with a cathode of mercury produces an amalgam of the two metals. I observed that by simple immersion of arsenic, antimony, tellurium, bismuth, zinc, cadmium, tin, lead, iron, cobalt, nickel, copper, brass, German silver, mercury, or silver, in a solution of tetrachloride of platinum, they became coated with that metal. According to Lan, a solution of one part of platinic chloride in 15 parts of alcohol and 50 of ether, deposits platinum on tin, brass, and white metal (*Jour. Chem. Soc.*, Vol. XLII., 1882, p. 1,145). Böttger adds carbonate of sodium to platinic chloride as long as carbonic anhydride is evolved, then a little starch sugar, and finally chloride of sodium, till the precipitated platinum appears white. The resulting solution coats articles by simple immersion (Watts's "Dictionary of Chemistry," Vol. VI., p. 950).

One of the best liquids for obtaining thick reguline deposits by the separate current process is that of Roseleur, who prepared it as follows:—Convert ten parts of platinum into dry tetrachloride, and dissolve it in 500 parts of distilled water (the whole should dissolve). Add, with stirring, to the solution, 100 parts of crystallised phosphate of ammonia previously dissolved in 500 parts of distilled water; and as this produces a precipitate, add at once, with copious stirring, a ready made solution of 500 parts of crystalline phosphate of soda in 1,000 parts of distilled water. Boil the mixture until an odour of ammonia ceases and the liquid begins to turn blue litmus paper red. The liquid must be used hot, and a strong current must be employed, because an anode of platinum does not dissolve in it. It is decomposed by, and deposits platinum upon, zinc, tin, or lead by simple contact. A solution made by dissolving tetrachloride of platinum in one of potassic cyanide has also been used for the same purpose, but it also does not dissolve a platinum anode.

## CURRENT ENERGY.—XIV.

BY OLIVER HEAVISIDE.

(CONTINUED FROM PAGE 271.)

*Contact Force and Helmholtz's Electric Layers.*

An important hypothesis regarding Contact Force was advanced by Helmholtz in his classical Essay on the Conservation of Energy, of which a preliminary idea may be gained from the following sentences:—"It is evident that all phenomena in conductors of the first class (*i.e.*, those in which conduction of electricity takes place without electrolysis) follow from the assumption that different chemical elements have different attractions for the two electricities, which attractions act only through immeasurably small distances, whilst the electricities can act upon one another at greater distances also. The contact force will then consist in the difference of attraction which the particles of metal lying next the junction exert on the electricity at this place; and electrical equilibrium occurs when a particle of electricity which goes over from one to the other metal no longer either gains or loses kinetic energy."

This is part of Helmholtz's explanation of the phenomena which occur when two metals are put in contact, that they become oppositely charged and apparently at different potentials. To it we must add a brief statement of what is meant by the double electric layer. Assume that there is really an E.M.F. at the junction of two metals (we are not specially considering thermo-electricity), some tendency to produce a current from one to the other, to be measured by the amount of energy taken in per unit of electricity, and which must produce a current unless otherwise balanced—the place where the energy is taken in being the seat of the E.M.F. We must not suppose the E.M.F. to be confined strictly to a mathematical surface, but to extend through a small thickness $t$, so that if E be the E.M.F. from A to B, the impressed force per unit of length is $E/t$. If the conductors A and B are insulated there can be no continuous current, whether they are in contact at one or at any number of different places, provided in the latter case the junction E.M.F.'s are all equal, and all from A to B. Hence only one junction need be considered. Equilibrium of electricity requires that there shall be no electric force in any part of the conductors, including the junction. Therefore the impressed E.M.F. $E/t$ from A to B must be balanced by an equal force $E/t$ acting from B to A through the thickness $t$ at the junction, which will make the potential of A exceed that of B by the integral amount of this force, viz., E. Now, considering the force of reaction alone, we see that the field of force exactly resembles that between the plates of a charged condenser, for we have two opposed parallel surfaces with electric force acting normally to them through the intermediate space. The conclusion is that at the junction of A and B there is a double electric layer, a layer of positive electricity on the A side, and of negative on the B side, at the terminations of the lines of force, and that it is this double layer that is the cause of the electric equilibrium.

Before going further it will be well to distinctly separate four things.

(*a*). There is first the hypothesis that the contact force resides at the metal junction.

(*b*). Next, the hypothesis that it arises from different kinds of matter attracting electricity differently, though only at insensible distances.

(*c*). The statement that this E.M.F. is balanced by an equal, but oppositely directed force of reaction.

(*d*). The hypothesis that this force of reaction proceeds from a double electric layer.

Three hypotheses and one statement have to be considered, and we will take them in the order in which they are most easily disposed of. Commencing with the statement (*c*), there is very little to be said, because the statement is not open to any question. The most elementary notions regarding the balance of forces render the electrical example self-evident. If there is no current at any particular part of a conductor, there is no resultant electric force there; hence if there be any impressed force it must be balanced by a reaction.

(*a*). Now, regarding the first hypothesis, we have in Art. XIII. given reasons against this view as respects the ordinarily observed differences of potential of metals in contact—the "contact force" of ·75 volt between copper and zinc, for example—so its discussion here is rendered unnecessary. There is, however, a comparatively minute E.M.F. of thermal origin undoubtedly existing at the contact place of different metals, and probably the same occurs at the junction of any two materials.

(*b*). The second hypothesis is, from its very material and speculative character, difficult either to grasp or to manipulate. It was intended to apply to the large differences of potential just now mentioned, and, speaking from memory of Helmholtz's Faraday Lecture delivered a few years ago, that scientist still maintains it, as well as the hypothesis of electric layers, to be later discussed. We may, however, apply (*b*) to the thermo-electric force at a metallic junction, or to air contacts, or by generalisation to any contact force we may choose to imagine. If copper and zinc attract electricity differently, though only at insensible distances, the differential force must certainly cause a momentary current across the junction when they are set in contact. And the same result would happen if the heat in the copper attracted electricity more than the heat in the zinc, or the same might be said of the ether, or if any other possible or impossible kind of differential attraction existed. Now, it is surely difficult enough to form a mental conception of what is happening when any kind of impressed E.M.F. is acting, with its corresponding transformation of energy, even when we know definitely that heat or chemical affinity is concerned. But contact force with the supposititious attraction of matter for electricity is rather harder to understand than without it. For the differential attraction being E.M.F., so are the separate attractions E.M.F.'s. Now, matter attracts matter, or, at any rate, things go on as if such were the case. But does matter attract electricity? Even on the material hypothesis of the direct action of electricity on electricity by attractive or repulsive forces, it is an enormous complication of the functions and properties of electricity to

Digitized by Google

admit of attractive force between matter and electricity. The supposed attraction of matter for matter is one kind of force, consistent in itself; that of electricity for electricity another kind, also self-consistent. But innumerable difficulties arise as soon as we admit the kind of cross action supposed. We need not go into details; they will readily suggest themselves to any one acquainted with the theory of the dimensions of physical magnitudes. Apart from this side of the question, difficulties crop up on all sides when we pass from mere momentary currents to continuous currents, with continuous expenditure of energy in keeping them up, as in thermo-electric or voltaic circuits.

The following special argument is used by Clausius. He observes that whether observed differences of potential occur only through the differences in the attraction of metals for electricity may be left an open question, but he denies that all phenomena may be thus explained, that the hypothesis is, in fact, inadequate to explain thermo-electric currents. Thus, if two metals, A and B, form a closed circuit, and B attracts electricity more than A, B will take a positive and A a negative charge of sufficient amount to balance the difference of attraction, and there will be an end of it. If we heat one of the junctions we cannot get a current unless the attraction of A or B for electricity varies with the temperature, which Clausius considers very improbable. Even allowing that such is the case, the result must be that every part of each metal will receive just as much electricity as it attracts, and there will be a state of equilibrium set up again. Thus Helmholtz's explanation is certainly incomplete. There is nothing to keep up the current.

Now Clausius, in other respects, agrees with Helmholtz's views, which, by the way, he observes are accepted by most other scientists (presumably continental, and as regards the contact layers mainly). But in order to bring them into harmony with the facts of thermo-electricity, he proposed the following addition:—"Heat itself is active in the creation and maintenance of the difference of potential at the junctions; for the molecular motion which we call heat tends to drive electricity from one to the other material, and this can only be stopped by the opposing force of the two electric layers thereby produced, when they have reached a certain thickness."

Having observed that Clausius, in his "Discussionen," pointedly called attention to the absence of any explanation of the origin of thermo-electric currents in Sir W. Thomson's papers on the subject, I was very curious to ascertain Clausius's explanation of the same in his chapters on Thermo-electricity. It is contained in brief in the last quoted sentence. But since the electric layers are surely not specially concerned with the Peltier contact force, but, if existent at all, are equally valid for any similarly situated impressed E.M.F., we find Clausius's explanation reduced to the statement regarding heat in the first part of the sentence, or any elaboration thereof not introducing any new hypothesis. This is rather disappointing. For what is contained therein beyond the recognition of the experimentally sufficiently obvious fact that heat is the source of the energy of the currents? Now, the reversible absorptions and evolutions of heat actually form the basis of Sir W. Thomson's theory, without explanation, of course. And also without any electric layers being brought into active co-operation.

An explanation of thermo-electricity will have to include not only the solution of the electrical problem in general, what actions take place necessarily during the existence of a current in a conductor or a dielectric however set up, but also how matter in its incessant agitations acts upon the electric system, using this term to indicate, very vaguely, an omnipresent agency of some kind, which must work according to dynamical laws. That electric currents are due to differential actions of matter on the system may be concluded from the various modes of electric excitement. It is, then, easily inferred that the action of matter on the system is always going on, that balanced states are of the kind exemplified in the theory of exchanges in the science of radiation, where bodies are continually emitting and receiving heat, and their molecules and the intermediate medium kept in a state of perpetual motion whilst every part remains in a stationary state on the average. All the various known actions of electricity will have to be included in one harmonious whole, consistent all round. It will have to be nothing short of a union of all the exact sciences with molecular science. That is for the future. For the present it would be a great step forward to know what relations the mysterious thermo-electric power of substances bears to their other physical properties. Here is a large field for investigation. And yet it is nothing. For we may be sure of this, that what is known is infinitely little compared with what is behind, and that the scientific investigator will never have reason to close business any earlier on account of the lack of matter for investigation, even keeping to terrestrial phenomena, let alone the study of the solar dermatology and other far away phenomena.

In the meantime the many cobwebs which have accumulated in electrical science have to be brushed away. Whether the hypothesis (*b*) of the attraction of matter for electricity should be considered a cobweb we may leave an open question. But as I long ago found out that it is better to have no staff at all than one which causes its user to be precipitated violently to the ground when he leans on it, so, summing up the matter judicially, I have to make the following additional assumption, viz., that the differential attraction of matter for electricity is a kind of electrical Mrs. Harris, and that the remarks of Betsy Prig regarding that mythical personage are appropriate. Said she on a certain momentous occasion, "Bother Mrs. Harris!" and later "I don't believe there's no sich a person!"

The remaining scientific hypothesis (*d*) is of a very different nature and of far greater importance, but it involves such extensive considerations of fundamental electrical laws that it must be left over to the next article.

---

## ELECTRIC LAUNCHES.*

BY A. RECKENZAUN.

(CONCLUDED FROM PAGE 307).

Large sums of money have virtually been thrown away in the endeavour to produce energy, and there are intelligent persons who to this day imagine that, by indefinitely increasing the strength of a magnet, more power may be got out of it than is put in.

Large field-magnets are advantageous, and the tendency in the manufacture of dynamo machines has been to increase the mass of iron, because with long and heavy cores and pole pieces there is a steady magnetism ensured, and therefore a steady current, since large masses of iron take a long time to magnetise and demagnetise; thus very slight irregularities in the speed of an armature are not so easily perceived. In the case of electro-motors these conditions are changed. In the first place, we assume that the current put through the coils of the magnets is continuous; and, secondly, we can count upon the momentum of the armature, as well as the momentum of the driven object, to assist us over slight irregularities. With electric launches we are bound to employ a battery current, and battery currents are perfectly continuous—there are no sudden changes; it is consequently a question as to how small a mass of iron we may employ in our dynamo as a motor without sacrificing efficiency. The intensity of the magnetic field must be got by saturating the iron, and the energy being fixed, this saturation determines the limit of the weight of iron. Soft wrought iron, divided into the largest possible number of pieces, will serve our purpose best. The question of strength of materials plays also an important part. We cannot reduce the quantity and division to such a point that the rigidity and equilibrium of the whole structure is in any way endangered.

The armature, for instance, must not give way to the centrifugal forces imposed upon it, nor should the field magnets be so flexible as to yield to the statical pull of the magnetic poles. The compass of this paper does not permit of a detailed discussion of the essential points to be observed in the construction of electro-motors; a reference to the main points may, however, be useful. The designer has first of all to determine the most effective positions of the purely electrical and magnetic parts; secondly, compactness and simplicity in details; thirdly, easy access to such parts which are subject to wear and adjustment; and, fourthly, the cost of materials and labour. The internal resistance of the motor should be proportioned to the resistances of the generator, and the

* Paper read at the Society of Arts on Wednesday Jan. 16, 1884.

Digitized by Google

conductors leading from the generator to the receiver. The insulation resistances must be as high as possible ; the insulation can never be too good. The motor should be made to run at that speed at which it gives the greatest power with a high efficiency, without heating to a degree which would damage the insulating material. Before fixing a motor in its final position, it should also be tested for power with a dynamometer, and for this purpose a Prony brake answers very well. An ammeter inserted in the circuit will show at a glance what current is passing at any particular speed, and volt-meter readings are taken at the terminals of the machine, when the same is standing still as well as when the armature is running, because the E.M.F. indicated when the armature is at rest alone determines the commercial efficiency of the motor, whereas the E.M.F. developed during motion varies with the speed until it nearly reaches the E.M.F. in the leads ; at that point the theoretical efficiency will be highest.

Calculations are greatly facilitated, and the value of tests can be ascertained quickly, if the constant of the brake is ascertained; then it will be simply necessary to multiply the number of revolutions and the weight at the end of the lever by such a constant, and the product gives the horse-power, because, with a given Prony brake, the only variable quantities are the weight and the speed. All the observations, electrical and mechanical, are made simultaneously. The electrical horse-power put into the motor is found by the well-known formulæ C × E ÷ 746 ; this simple multiplication

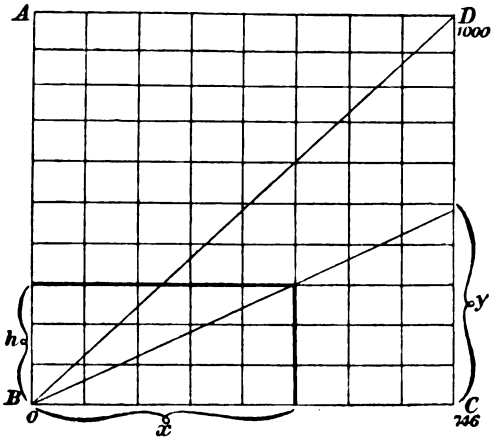

Fig. 1.--Reckenzaun's Electrical Horse-power Diagram.

and division becomes very tedious and even laborious if many tests have to be made in quick succession, and to obviate this trouble, and prevent errors, I have constructed a horse-power diagram, the principle of which is shown on the sheet on this wall (Fig. 1).

### Reckenzaun's Electrical Horse-power Diagram.

Draw a square A B C D—divide B C into 746 parts, and C D into 1,000 parts, or, generally, the division on C D is ·746 of a division on B C, so that we can use the horizontal lines cutting A B as a horse-power scale. A B, in the above diagram, gives 1,000 horse-power, if the line B C represents 746 volts, and C D 1,000 amperes. Let $x$ = any number of volts, $y$ the amperes, and $h$ the horse-power, then

$$\frac{h}{x} = \frac{y}{746} \therefore h = \frac{xy}{746}.$$

A fine wire or thread stretched from $o$ as a centre to the required division on C D will facilitate references.

Graphic representations are of the greatest value in all comparative tests. Mr. Gisbert Kapp has recently published a useful curve in *The Electrician*, by means of which one can easily compare the power and efficiency at a glance.

The speeds are plotted as abscissæ, and the electrical work absorbed in watts divided by 746 as ordinates ; then with a series-wound motor we obtain the curve E E. The shape of this curve depends on the type of the motor. Variation of speed is obtained by loading the brake with different weights. We begin with an excess of weight which holds the motor fast, and then a maximum current will flow through it without producing any external work. When we remove the brake altogether, the motor will run with a maximum speed, and again produce no external work, but in this case very little current will pass ; this maximum speed is $o\,m$ on the diagram. Between these two extremes external work is done, and there is a speed at which this is a maximum (Fig. 2). To find these speeds we load the brake to different weights, and plot the resulting speeds and horse-powers as abscissæ and ordinates producing the curve B B. Another curve $e = \frac{B}{E}$, made with an arbitrary scale, gives the commercial efficiency ; the speed for a maximum external horse-power is $o\,a$, and the speed for the highest efficiency is represented by $o\,b$. In practice it is not necessary to test a motor to the whole limits of this diagram, it will be sufficient to commence with a speed at which the efficiency becomes appreciable, and to leave off with that speed which renders the desired power.

We have next to consider the principle of applying the motive power to the propulsion of a launch. The propellers hitherto practically applied in steam navigation are the paddle-wheel and the screw. The experience of modern steam navigation points to the exclusive use and advantage of the screw propeller where great speed of shaft is obtainable, and the electric engine is pre-eminently a high-speed engine, consequently the screw appears to be most suitable to the requirements of electric boats. By simply fixing the propeller to the prolonged motor shaft, we complete the whole system, which, when correctly made, will do its duty in perfect order, with an efficiency approaching theory to a high degree.

Whatever force may be imparted to the water by a propeller, such force can be resolved into two elements, one of which is parallel, and the other in a plane at right angles to the keel. The parallel force alone has the propelling effect ; the screw, therefore, should always be so constructed that its surfaces shall be chiefly employed in driving the water in a direction parallel to the keel from stem to stern.

It is evident that a finely-pitched screw, running at a high velocity, will supply these conditions best. With that beautiful screw lying on this table, and made by Messrs. Yarrow, 95 per

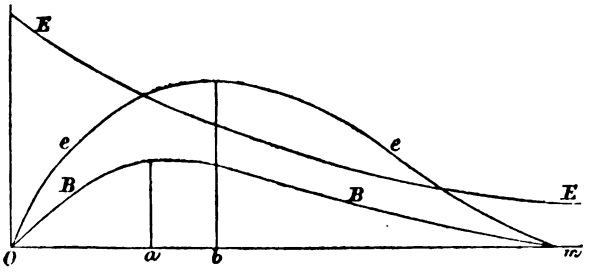

Fig. 2.—Kapp's Curve.

cent. of efficiency have been obtained when running at a speed of over 800 revolutions per minute, that is to say, only 5 per cent. was lost in slip.

Reviewing the various points of advantage, it appears that electricity will, in times to come, be largely used for propelling launches, and perhaps something more than launches.

In conclusion, quoting Dr. Lardner's remarks on the subject of steam navigation of nearly fifty years ago, he said :—

"Some, who, being conversant with the actual conditions of steam engineering as applied to navigation, and aware of various commercial conditions which must affect the problem, and were enabled to estimate calmly and dispassionately the difficulties and drawbacks, as well as the disadvantages, of the undertaking, entertained doubts which clouded the brightness of their hopes, and warned the commercial world against the indulgence of too sanguine anticipations of the immediate and unqualified realisation of the project. They counselled caution and reserve against an improvident investment of extensive capital in schemes which must still be regarded as experimental, and which might prove its grave. But the voice of remonstrance was drowned amid the enthusiasm excited by the promise of an immediate practical realisation of a scheme so grand.

"It cannot," he continues, "be seriously imagined that any one who had been conversant with the past history of steam navigation could entertain the least doubt of the abstract practicability of a steam vessel making the voyage between Bristol and New York. A steam vessel, having as cargo a couple of hundred tons of coals, would, *cæteris paribus*, be as capable of crossing the Atlantic as a vessel transporting the same weight of any other cargo."

Dr. Lardner is generally credited with having asserted that a steam voyage across the Atlantic was a "physical impossibility," but in the work from which I took the liberty of copying his words he denies the charge, and says that what he did affirm was that long sea voyages could not at that time be maintained with that regularity and certainty which are indispensable to commercial success, by any revenue which could be expected from traffic alone.

The practical results are well known to us ; history repeats itself, and the next generation may put on record our weak attempts, our doubts and fears of this day. Whether electricity will ever rival steam remains yet to be proved ; we may be on the threshold of great things ; the premature enthusiasm has subsided, and we enter upon the road of steady progress.

# DIRECT-READING ELECTRIC MEASURING INSTRUMENTS.*

BY PROFESSORS W. E. AYRTON, F.R.S., AND JOHN PERRY, M.E.

(CONCLUDED FROM PAGE 347.)

In our direct-reading commutator instruments the scale is double, as may be seen from Fig. 2 the upper numbers corresponding with the number of amperes, or volts, when the commutator is to series, the lower when to parallel.

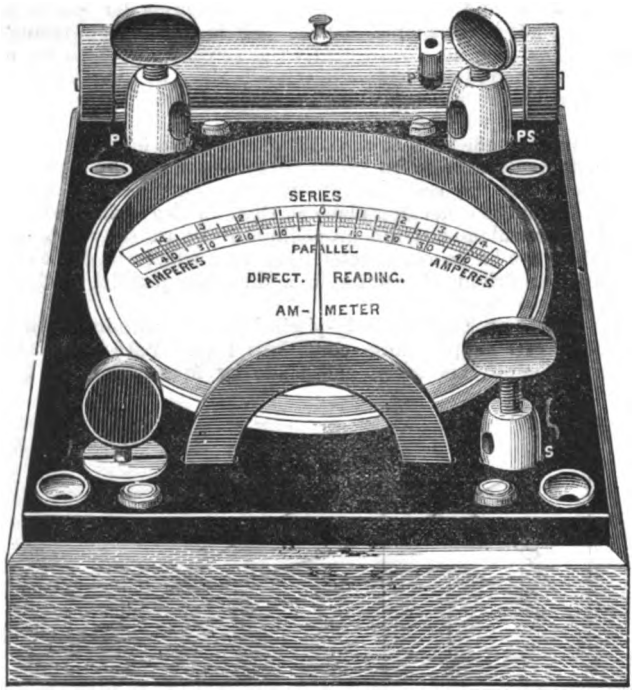

FIG. 2.—Direct Reading Commutator Instrument.

Fig. 3 shows the interior of the latest form. N is the bobbin round which the wire is coiled ; H H is the permanent controlling magnet, made in two parts to obtain considerable strength ; S is one of the soft iron pole pieces of special shape, to be referred to further on ; K K are the soft iron cores ; and Y Y is a connecting bridge-piece of charcoal iron used in our latest form of instrument for increasing the strength of the deflecting field for a given current by connecting magnetically these iron cores together. This addition is very important in voltmeters, since, although in an ammeter the constant of the instrument is nearly independent of temperature, this is not the case in a voltmeter. The current producing a given deflection in either instrument is practically independent of temperature, but the potential difference necessary to be maintained at the terminals of the

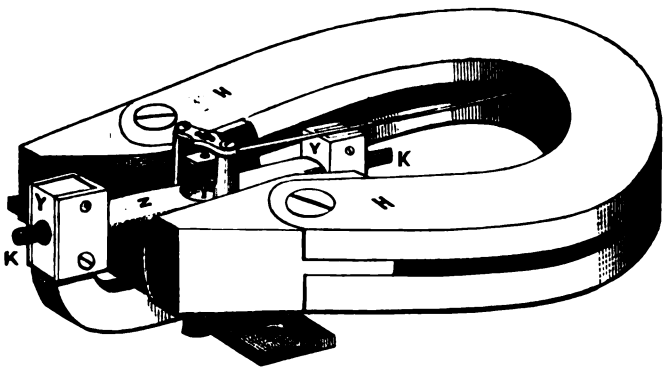

FIG. 3.—Interior of Direct Reading Instrument—Latest Form.

instrument to produce the current, and which potential difference is what the voltmeter is designed to measure, depends necessarily on the resistance, and therefore on the temperature of the coil. A temperature correction can be easily made for the portion of the effect arising from the temperature of the room, but the unknown amount of heating of the coil arising from the passage of the current it is far more difficult to allow for. Hence it is generally necessary to be contented with a weaker controlling permanent magnet for a voltmeter, in order that the magnetic effect necessary to produce any given deflection, and consequently the heating effect, which is proportional to the square of this magnetic effect, shall be less in the case of a voltmeter than in an ammeter. But the employment of our soft iron pole pieces combined with the soft iron bridge enables us to use much more powerful controlling magnets, and therefore to obtain a much greater dead-beatness and a greater freedom from disturbances produced by extraneous powerful magnets with our last form of voltmeters than with our earliest.

*German Silver or Copper Wire for the Coil of a Voltmeter.*—It might appear at first sight that German silver wire would be better than copper wire for voltmeters. As regards the error arising from the change of temperature of the room this is undoubtedly the case, but not as regards the heating of the coils by the passage of the current. For, to produce any given deflection on a voltmeter provided with a given controlling permanent magnet requires a given current for a given number of convolutions. Hence, since the specific resistance of German silver is about thirteen times that of copper, the production of heat which necessarily accompanies the production of a given magnetic effect with a given instrument will be thirteen times as great if German silver be used than if copper be used. And, on account of the inferior heat-conducting power of the German silver, the elevation of temperature will be more than thirteen times as great. But for the same elevation of temperature the increase of resistance of copper is only 8·8 times the increase of resistance of German silver. Consequently, copper wire will be about twice as good as German silver in any case where the change of resistance, due to the heating produced by a current flowing through a given coil, is concerned.

*Methods of Construction for Obtaining the Proportional Law.*—Next, with reference to the principle that must be followed to obtain the proportional law in galvanometers. In an ordinary galvanometer controlled by the earth magnetism the strength of the controlling field is a uniform one, whereas the strength of the deflecting field produced by the current flowing round the coil is strongest in the plane of the coil and

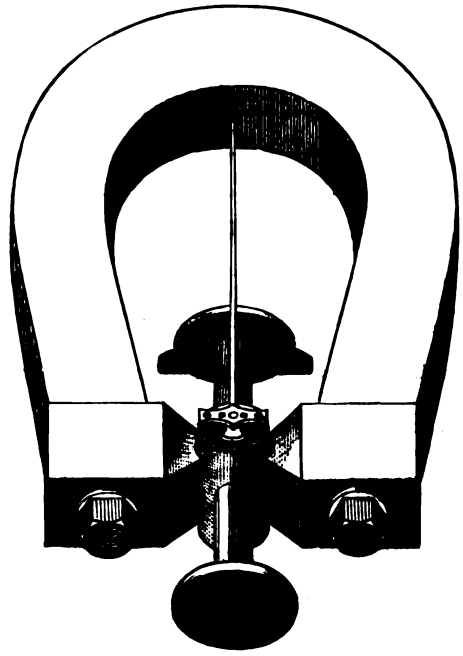

FIG. 4.—Interior of Direct Reading Instrument—Earlier Form.

grows weaker as we recede from that plane. Hence, when the needle is deflected it moves into a weaker part of the deflecting field. The result of this is that the deflections for different currents increase much less rapidly than the current. If both fields be uniform for all positions of the needle, and be at right angles to one another when the needle is in its zero position, then, as is well known, the tangent of the deflection increases proportionately to the current. In order, then, that the deflection may increase proportionately with the current, one of three conditions must be fulfilled :—(1) The needle when deflected must move into a stronger part of the deflecting field, or (2) must move into a weaker part of the controlling field, or (3) both these results must be true. The first condition, uniformity of controlling field, combined with increase of strength of deflecting field, can be fulfilled by using two solenoids at a small distance apart from one another, but with a common axis, and suspending the needle between them, so that on being deflected it enters the solenoids, and therefore moves into a stronger part of the solenoid field ; or it may be fulfilled by suspending a magnet over two flat horizontal coils, the distance between the coils being rather less than the length of the needle. This mode we employ for making a rough student's laboratory galvonometer, which you see in its embryo state on the table, and with which the deflections are accurately proportional to the current, at any rate up to 45deg. or 50deg. If, however, a dead-beat instrument is required, then, in order to ensure roughly uniformity of controlling field, the pole pieces of the permanent magnet must be hollowed out, as shown in Figure 4, and must embrace the tube in which the needle moves. We have made a number of ammeters and voltmeters of this type, and a sample one dissected is on the table. The augmentation of strength of

* Read at the Physical Society of London, January 26th.

Digitized by Google

the deflecting field is still further produced by the employment of the soft iron cores referred to above, which screw into a brass bobbin.

But condition 3, the needle moving into a stronger part of the deflecting field, and also into a weaker part of the controlling field, is the one we find the best, and it is the one we are using in all our latest instruments. the interior of one of which is shown in Figure 3.

*Change of Strength of the Controlling Magnet.*—In some of our older instruments we have found that the constant did not suffer sensible change during a period of many months, in others that the change during a much less time arising from the falling off of the strength of the controlling magnet was very serious. This latter effect, we believe, to be partly due to inferiority in the steel, it being very difficult to obtain successive deliveries of magnet-steel from the same manufacturer equally good in quality, and partly from the way in which the armature attached to the instrument when not in use, was removed from the magnet when about to be used. In some of our older instruments from the form of construction, the mode of removal of the armature took rather the form of a pull, which is known to be bad for the permanency of a magnet. Consequently our new non-commutator instruments are so arranged as to make it impossible to use armatures at all; while in our commutator instrument armatures are attached, but the instrument is so constructed that the armature can only be removed by a pure sliding motion, and we shall thus be able to ascertain experimentally whether no armature at all, or an armature put on and removed by a pure sliding action, is better for keeping the controlling magnet constant in its strength.

*Ohmmeters.*—The ohmmeter, as we have already said, we define to be an instrument in which the pointer points at once to the number of ohms required to be measured. The method we employ for making such an instrument consists in fixing two coils at right angles to one another, acting on the same soft iron needle. One of these coils (thick wire) is connected to the two inner terminals (Fig. 5), and is placed in series with the resistance to be measured, while the other (fine wire) coil is connected to the front terminals, and is put as a shunt to the unknown resistance. Hence, the main current produces its effect by means of the thick wire coil, and the difference of potentials at the terminals of the unknown resistance on the fine wire coil. Now, by properly proportioning the shapes of the coils, and by winding these coils in a definite way, we have obtained an instrument in which the deflection of the pointer is exactly

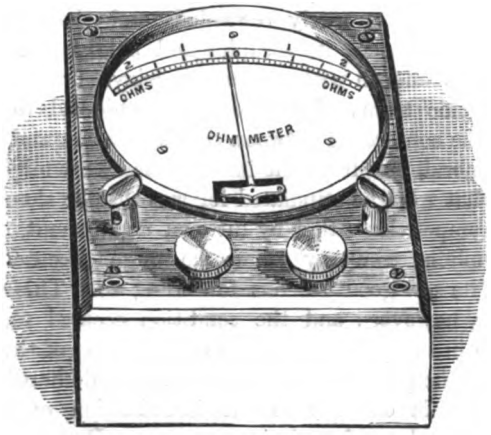

FIG. 5.—Direct Reading Ohm-meter.

proportional to the number of ohms, and which we find most convenient for measuring the resistance of any part of an electric circuit, such as the field-magnet of a dynamo, or the resistance of an arc lamp, while the strong current is flowing. The thick coil is always kept, like an ammeter, in the main circuit, and the terminals of the fine wire attached to any two points between which it is desired to know the resistance at any particular moment. The use of the instrument also permits the employment of an iron wire, or even of a bit of wet rope as a resistance coil for experimental purposes, the resistance of the iron wire or of the wet rope being determined with the ohmmeter at the moment the experiment is being made.

Sir William Thomson has recently proposed a new unit, a Mho, the reciprocal of an ohm, on account of the difficulty which is found in making people realise that one-thousandth of an ohm may be of great importance when you are dealing with a large current. But we do not propose graduating our ohmmeters as mho-meters, an operation, of course, quite simple to effect, because, first, if it be found that practical men cannot be got to pay attention to a thousandth of an ohm, we venture to think that they can probably be got to appreciate its value if it be called a thousand microhms, just as practical men do not disregard the capacity of a mile of submarine cable when called, as it always is, a third of a microfarad, although possibly they might do so if it were spoken of as one three-millionth of a farad; and, secondly, a still greater objection to the adoption of the word "mho" (ingenious as is this suggestion of Sir William Thomson's, like that of all his other suggestions) is because the constants in connection with conductivity, the reciprocal of resistance, are quite different from those connected with resistance. For example, take the case of increase of resistance with temperature. Let R be the resistance of a wire at a temperature $t°$ C., and $R_0$ that at 0° C. Then

$$R = R_0 (1 + a t)$$

when $a$ is the increase of resistance per ohm per degree.

Now let C and $C_0$ be the respective conductivities; then

$$C = C_0 (1 - a' t),$$

where $a'$ is the decrease of conductivity per degree per unit of conductivity.

But, since $R = \frac{1}{C}$,

and $R_0 = \frac{1}{C_0}$

$$\therefore 1 + a t = \frac{1}{1 - a' t}.$$

When $a \times t$ and $a' \times t$ are small, as in German silver, the percentage increase of resistance equals the percentage decrement in conductivity per degree, but if $a t$ is large, as in copper, this is not the case, so that while ·388 is the percentage increase of resistance of copper per degree ·293 is the percentage decrement of conductivity per degree.

*Non-sparking Key.*—Various so-called non-sparking keys have been devised during the last year or two, but as far as we are aware they by no means completely fulfil their object. On breaking a circuit through which a current is flowing, a spark is produced, the brilliancy of which depends on the co-efficient of self induction of the circuit, and on the current flowing through the circuit just before the circuit was broken. To completely avoid this spark the energy stored up in the circuit must be utilised to send a current through an unbroken circuit, and this can be accomplished if the resistance of the circuit, instead of being suddenly varied from a small value to infinity, is increased steadily by the insertion of a resistance increasing at a proper rate. If it increases too quickly a spark will certainly take place; if too slowly the wire of the resistance coil which has been added to the circuit will be dangerously heated.

Figure 6 shows an arrangement which we have devised for introducing this resistance at a proper rate independently of any control on the part of the person stopping the current. To start the current, the handle H is

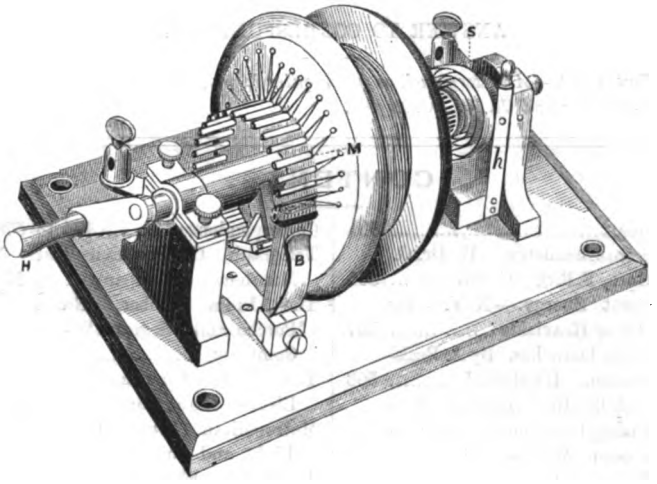

FIG. 6.--Non-Sparking Key.

turned moderately quickly until the solid piece of metal M comes into contact with the brush B, when a catch holds the key in that position. The current now passes from one of the binding screws to the other through practically no resistance. To stop the current, the little handle $h$ is slightly pulled, when a spring, S, which was coiled up when the handle was turned round to put the current on, causes the cylinder to turn in the opposite direction the various metal pins, coming in succession into contact with the brush B. Between each of these pairs of metallic pins there is a resistance varying from a small fraction of an ohm for the first coil to some hundreds of ohms for the last. The effect is, then, that resistance at a perfectly definite rate is added to the circuit before breaking it. These resistances are adjusted partly by calculation and partly by trial, so that, with the particular rate of rotation the coiled spring $s$ gives to the barrel of the key, the circuit of an A Gramme machine sending a fairly strong current can be broken, by the use of this key, without any visible spark. The spring S, combined with the locking arrangement, makes it impossible for the key to be left partly on or off. If not put so that the current flows without resistance, then the spring breaks the circuit altogether.

Besides the advantage this key affords of being able to break an entire electric light circuit without spark, it is possible that another advantage may be produced, viz., that the life of incandescent lamps may be increased by the current which passes through them being always gradually diminished to nothing, instead of being suddenly stopped, as is at present the common practice; but whether this second advantage exists, time, of course, alone can show. At any rate the existence of a non-sparking key now makes it possible for insurance companies to turn their attention to the question of prohibiting sparking altogether, which hitherto it has been almost useless contemplating.

## COMPETITIVE TELEPHONY.

If the letter which the Manager of the Globe Telephone Company published in *The Times* last Monday may be accepted as a true description of the policy of the rival United Telephone Company, we have a simple explanation of what at the time appeared the somewhat unintelligible proceedings of the deputation from Portsmouth which waited upon the Postmaster-General on the Wednesday preceding. That deputation, which was of a most influential character, professed to represent the inhabitants of Portsmouth pitifully begging to be allowed to have a telephonic system like other towns of not greater importance, but which they were debarred from having by Mr. Fawcett himself, who stood in the way of an enterprising telephone company, ready and anxious to confer this boon upon them. It turned out, however, that it is the company itself that is holding back, that the Postmaster-General rather encourages the enterprise than otherwise, and only imposes conditions which at other places and by other companies have been accepted, but which the company now waiting at the gates of Portsmouth declines to accept.

One would have expected under the circumstances that a company desirous of pushing its business, but hindered by vexatious conditions, would have appealed in person against them. Perhaps it has done so in a less public way; but recognising the advantages of a public demonstration it appears to have worked up the expectations of the Portsmouth people, and then dashed them against the head of the Post Office. Everything is in readiness for a grand installation of telephony, much cheaper and of course quite as good—though the deputation was discreetly reticent on this point—as any that the Post Office or competing company could offer; but unless the inhabitants of our great naval station would go to London in their thousands, or, what counts for as much, in the persons of their borough members, their town councillors, their chambers of commerce—and obtain the removal of a certain "condition" there would be no telephone for Portsmouth, the projecting company having threatened to withdraw from the place altogether. This was an exceedingly clever stroke on the part of the company; and though it entailed a good deal of unnecessary trouble upon the local dignitaries of Portsmouth, they have earned the gratitude of the telephone company if nothing else. It may be hoped that they will be properly rewarded, and that the bashful telephone will pocket its scruples and boldly enter the precincts of Portsmouth without further delay.

The specific terms of the condition objected to were not stated at the conference between the deputation and the Postmaster-General, but from the latter's remarks it might be conjectured that what he stipulated for was that he should be free to allow competition either by his own department, or by any other telephone company whom he might license for that object, if he saw good reasons for doing so. This was only conjecture, however; and the condition seemed so fair and reasonable in the public interest, to say nothing of the financial interests of the postal telegraphs, that one could hardly imagine it was the sole obstacle to the introduction of telephonic service into a place of such importance as Portsmouth. But the letter of Mr. Law, above alluded to, roundly asserts that this was the only obstacle, and that, in fact, the United Telephone Company are trying to put pressure on the Post Office authorities to grant a monopoly whenever they grant a license—at all events to the United Telephone Company. Mr. Law, who is the general manager of the Globe Company, himself complains that the conditions of the licenses are very severe, which, from what follows, we gather to mean that the Post Office will not take part in or permit unrestricted and unlimited competition—which is what the Globe Company appears anxious to inaugurate—just at present. But he points out that the aim of the United Company is, on the other hand, to obtain a monopoly for itself; and the assertion is so far borne out that undoubtedly this would be the practical effect of abrogating the conditions which the Post Office has latterly deemed it necessary to introduce into all its licenses, whether to the United or to any other company. Now, we have so often expressed our opinion on the subject of monopoly *versus* free competition, that we need not reiterate our arguments on the present occasion; but accepting the situation as it stands, the Post Office being unwilling to enforce its legal right to a monopoly, the next best thing, and indeed the only endurable thing, is to content ourselves with competition under some sort

Digitized by Google

of reasonable restriction. A monopoly of any sort would be preferable to competition of every sort; and this latter we are rejoiced to see the Post Office is still determined not to permit.

What, then, was the alternative course left open to the Postmaster-General when he found that the one competitor who had fought and lost a legal battle with him, but whom he refrained from annihilating, threatened to become a monopoly by itself? Obviously he could not allow those rights which he had waived to be assumed by somebody else. The United Telephone Company had fought against a monopoly; if it had won the day it could hardly expect to have won also a monopoly for itself; and as in reality it lost the day its tactics to secure a monopoly, although perfectly defensible on commercial grounds, cannot be allowed to pass without criticism, or to escape those protests against monopoly which were so freely used on its behalf when it wanted elbowroom for its own operations. It may be safely assumed that a public department will not interfere either directly or indirectly with a license so long as the lessors take no improper advantage of the privilege conferred upon them —that is to say, so long as the public are adequately served and on reasonable terms. Reservation to step in or to allow others to step in where this condition seems to have been disregarded will operate very much to the benefit of the public; and it seems to us that any company asking for a license and intending to do its business efficiently for a fair remuneration need have no hesitation in accepting the contingent risk of competition should there be a failure in either of these particulars.

## THE LATE COMTE DU MONCEL.

The death of this eminent electrician was but briefly noticed in our last issue. As a detailed account of his inventions and writings would far exceed the space at our disposal, we shall confine ourselves to the mere mention of the chief works, which were sufficient, and more than sufficient, to establish the deceased gentleman's reputation.

Théodore Achille Louis, Comte du Moncel, was born in Paris the 6th March, 1821. His father was a distinguished general and peer in the reign of Louis Philippe. After leaving the college of Caen, and when hardly eighteen years of age, he published his first work, a "Traité de Perspective Mathématique," soon followed by another, "Traité de Perspective Apparante." The late Count then travelled for some time in the South of Europe, and in the East, and upon his return, in 1847, published a large work, "De Venise a Constantinople à travers la Grèce," of which he lithographed the drawings himself. It was in 1852, writing in the *Journal de l'Arrondissement de Valognes*, that Du Moncel first treated of electrical matters, by describing the inventions that then began to attract attention to a science that has since received such an enormous theoretical and practical development. From this period Du Moncel's writings on the subject were continued to the day of his death. His chief work, and one of his earliest, "Exposé des Applications d'Electricité," was printed in two volumes, in 1853-4, and was finally republished and enlarged to five volumes.

His books, "Le Telephone," "L'Eclairage Electrique," "Le Microphone et le Phonographe," "L'Electricité comme Force Motrice," "Traité de Télégraphie Electrique," "Notice sur la Bobine de Ruhmkorff," and many others, appeared in quick succession, and were certainly the works that chiefly spread popular information upon the subjects of which they treated. His reports to the Academie des Sciences and his pamphlets upon electricity and magnetism were many; the library of the Society of Telegraph Engineers and Electricians contains some 65 printed works of this indefatigable author.

In 1860 the Comte du Moncel was named member of the technical committee of the French Administration of Telegraphs; in 1866 he was made Officier de la Legion d'Honneur; in December, 1874, was received as Membre de l'Academie des Sciences; and in 1879 undertook the scientific editorship of *La Lumière Electrique*, in which was published a regular series of most interesting and exhaustive articles upon all the most important electrical problems that now occupy the attention of *savants*.

Du Moncel was not only a writer but a practical electrician and inventor, though none of his instruments have received much actual application. He was a most careful experimenter himself, verifying most of the effects he described.

The late Count's chief claim to the gratitude of the present generation is that he more than any other author popularised, and we may say vulgarised, the science and application of electricity. His works in France at least, and more especially those on the Telephone, Microphone and Electric Lighting, were exposed for sale on all the book stands, and were as much read by the public who desired instruction and information as by purely scientific men.

His facility in handling his pen and accurately setting forth a theory or describing an instrument in the most intelligent manner was truly wonderful. The writer has frequently seen the Count, after listening to a long description of a complicated instrument, instantly transfer to paper a full account of it, condensed into comparatively few lines, but as plainly set forth and with such method and *suite* as to perfectly sum up the account of the invention.

In personal character he was of the most charming and affable disposition. Poor inventors, searchers seeking for scientific information, and all who took an interest in electrical matters were received with as much distinguished politeness as the greatest of *savants*, and his impartiality in his judgments and writings was not the least of his virtues.

The Count died at his town residence, 7, Rue de Hombourg, Paris, on the 16th ult., from an attack of apoplexy. His funeral took place at the church of Saint Louis d'Antin on the 20th, and was attended by all scientific Paris. There was a deputation of the Academie des Sciences, in official uniform, and the Society of Telegraph Engineers and Electricians of London, of which the deceased was an old and honoured member, was represented by Mr. J. Aylmer, hon. secretary for France.

The Comte du Moncel married the daughter of the Comte du Montalivet, by whom he leaves one daughter, now Madame Dursus. We much regret that the death of the Count has caused a serious relapse in the health of the gifted and amiable Countess, who at his death was barely convalescent after a long and dangerous illness.

# CORRESPONDENCE.

## THE PHYSICAL THEORY OF THE GRAMME MACHINE AND THE AMPERIAN CURRENT HYPOTHESIS.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: In my last letter under this heading I explained that the experiment described on p. 281 was intended for the numerous sufferers from defective methods of tuition who are under the delusion that the *north* or *south* character of "lines of force" determines the direction of the current induced when a magnet is inserted within a coil, and that, consequently, when the magnet is passed through the coil, the two opposite currents generated correspond to the N and S lines; so that, if the motion of the magnet be reversed, the directions of the two currents will be in reverse order. I admitted that the disproof of these views did not apply to the statement formulated by "E," since his proviso "that we are looking on that side of the coil which is the nearer to the magnet" implies that, in the experiment in question, the observer must reverse his position, and that therefore the *apparent* direction of the current will be reversed, and will thus be in accordance with the statement of "E."

Now, in your last issue Mr. W. H. Snell says:—"Mr. Fitz-

Digitized by Google

Gerald, as far as I can make out, wishes to explain the collapse of his *experimentum crucis* on the ground that he neglected to consider the position of the observer." He further remarks that "under the circumstances, it would have been equally pertinent to have noted the height of the barometer!" Then (having on a previous occasion given me the information that the direction of the induced currents depends upon the direction in which the N or S lines pass through the coil) he further enlightens me by pointing out that "to determine whether any two induced currents will be in the same or in opposite directions it is *seldom* necessary to consider the position of the observer."

This will be enough to begin with. How am I to reply to all this inconsequence? I do not wish to slight or to be "too hard on" a former pupil; and the dear boy is no doubt so happy under the impression not only that he has "caught out" his old professor in some mistake, but that he is going to disprove the universal applicability of the law of Lenz, that it is almost painful to undeceive him. I may, however, mildly point out that I obtained a practical acquaintance with the facts he points out at a period when I, as editor of the old *Electrician*, was examining into the *Holmes* and *Alliance* magneto-electric machines, and he was undergoing that change of attire known as "short-coating." I may also observe that my experiment cannot well be said to have "collapsed," since it is calculated to remove from the minds of many learners the false conclusions above adverted to, and shows very clearly that the observed effects may be accounted for by a simple reference to the law of Lenz, without considering whether the lines of force are *north* or *south*, whether we are looking on that side of the coil which is the nearer or the farther from the magnet, whether the lines of force are passing through the coil in the same direction or not, or what may be the "positive" or the "negative" direction of the currents induced by adding or by subtracting N or S lines of force. This experiment, by the way, should be more frequently shown in the class room, and should be varied by exerting an electro-magnet placed within a movable coil, which may be shifted from the north pole to the "neutral point" and thence to the south pole—being in each case traversed by a current in the same direction.

Passing now to Mr. Snell's objection to my mode of stating the law of the phenomena produced by "adding" lines of force to a coil, I will merely ask him to substitute for the words "not possible for both N and S lines of force to be added to the same face of the coil," the words "not possible to reverse the direction of the amperian current acting inductively on the coil." I am sorry I cannot even agree with Mr. Snell as to my statement of this law being "perfectly correct." Like all the statements as to the effect of "adding" or "subtracting" lines of force, it is correct only when taken in conjunction with certain conventional postulates. For instance, when a magnet is passed through a coil, it would be perfectly correct to say that N and S lines of force are successively "added" to the coil. But the currents induced would be in opposite directions. The only law I know of in this connection that is perfectly correct, without any complication of conditions—"to make it more difficult for us!" as the ingenuous student once surmised—is the law of Lenz.

In regard to my overlooking "the necessity for distinguishing the direction in which the lines of force enter the coil," I will let Mr. Snell into a little secret which I thought he might by this time have found out for himself, viz.: that I have, *de parti pris*, been particularly careful *not* to recognise any such necessity. Because I hold the opinion that, in explaining effects of magneto-electric induction, it is far preferable to recognise only the necessity for bearing in mind the direction of the amperian current acting in accordance with the law of Lenz.

In reference to Mr. Snell's statement of the law as to the addition and subtraction of lines of force, I really think he must try again to formulate something that will resist any kind of assault. The expression "always in the same direction" is so equivocal that the general verdict seems to be: "I can make neither head nor tail of it!" The most probable view is that it refers to the direction in which a magnet is moved through a coil; and this, I hold, is what Mr. Snell must mean. But others maintain that it must refer to the "direction of the lines," and they point to this expression in confirmation of their view. Some, again, who are accustomed to ascertain the actual direction of the current by Lenz's law, will "want to know, you know," whether the "positive direction" is that of the hands of a watch or the reverse.

Mr. Snell gives a diagram, in relation to which I would suggest that he is not likely to disprove the law of Lenz by placing a coil between two sets of amperian currents in the same direction, and in such close proximity that the effect of withdrawing the coil from one of these sets is sensibly compensated by that resulting from its approach towards the other. By an application of the principles of continuity, he may, however, satisfy himself that, in accordance with the law of Lenz, he will by moving the coil from one to the other pole generate two currents in opposite directions, albeit he may be quite unable to obtain any indication of them. For, if he places his similar poles sufficiently far apart, he may easily exhibit the two reverse "throws" by means of a reflecting galvanometer. Then, by gradually diminishing the distance between the poles he will gradually diminish the amplitude of the "throws," until he may require a more sensitive galvanometer to render evident the effect. When this happens, he may still perceive this effect in the "mind's eye."

In conclusion, I shall have to consider whether I may not be unduly occupying your space, Mr. Editor, and my own time, by continuing the present discussion under existing circumstances. It may profitably be resumed, perhaps, when experiment has shown whether or not an improvement can be made in dynamo machines of the Gramme type by the elimination of one of the induced currents generated, according to the explanation I have put forward, by the approach and recession of the coils to and from the theoretical poles of the field magnets.—Yours, &c.,

DESMOND G. FITZGERALD.

---

TO THE EDITOR OF THE ELECTRICIAN.

SIR: I have performed a number of experiments with a view to ascertaining why there should be "magnetic lines of force," and the results led me to believe that *a line or plane of least resistance* may be the explanation.

I found that when a current was passing through or along a soft charcoal iron wire, so-called "magnetic lines of force" were developed, which, in the plane at right angles to the wire, assumed the shape of a number of concentric circles, and, in the direction of the wire, of long tubes, if I may so describe them; in fact, they appeared to be like long tubes with intervening layers of air, or air tubes. I found when I placed this current-carrying wire into the magnetic field of a permanent magnet, and took the lines of force, that in every case the magnetic lines of force from the wire diverted the lines of force of the magnet to a very great extent, and herein lies, I believe, an element of disturbance beyond the generally accepted theory of the action of field magnets and armatures.

In the Gramme ring this element appears to act detrimentally, whereas in the Brush ring, owing to the way in which the current is arranged to circulate through the bobbins, it tends to act beneficially, as far as the generation of E.M.F. is concerned, by drawing more lines of force into the best position.

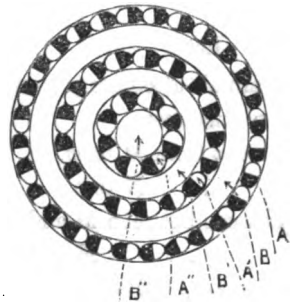
In many text-books I find a drawing showing the presumed disposition of the molecules in a bar, but they only give one ring A, leaving it an open question how the molecules in the remaining portion of the bar are disposed.

It is generally accepted that the molecules are in concentric circles, and therefore will have the same directive position in such concentric circles as A A′ A″, but what is their directive position in the intervening circles B B′ B″? If the bar is perfectly non-polar in all parts, then the molecules in these circles must have an opposite directive position. If the line of least resistance should be from east to west, then the molecules situated in the circles B B′ B″ will try to turn so as to arrange themselves in like order to those in circles A A′ A″, and it may be that this tendency to arrange themselves more or less in

Digitized by Google

their lines or planes of least resistance may help towards the explanation of what resistance may be.

From the above it will be seen that in the circles B B′ B″ two forces are at work, one, of the molecules in B trying to turn so as to offer a line or plane of least resistance, and the other of the molecules in A exerting their polar influence on the B molecules, to keep them in the polar order. Now, if the molecules in B were free, they would move according as to which force was the stronger, and if we assist them, as we can when the bar is represented by iron filings, we find so-called lines of force. During the time the molecules that were in circles B B′ B″ are in the air, and thus uninfluenced by the friction caused by contact with the paper, they arrange themselves in the same directive position as, and above, the molecules in circles A A′ A″. Thus the two forces which were in antagonism when the molecules were in circles B B′ B″ are acting together when the molecules are piled one over the other in circles A A′ A″.



This seems an explanation of the so called "lines of force," which would more correctly, I think, be called *paths of least resistance*.

My letter has become so long that I must leave over the question of "Resistance."—Yours, &c., B.

---

TO THE EDITOR OF THE ELECTRICIAN.

SIR: In your last issue "One of the Crowd" asks me, or rather defiantly challenges me, to explain the action of the Ferranti dynamo according to the lines of force theory. That theory is universal, and applies to every dynamo machine, those giving alternating as well as those giving continuous currents. In Fig. 1 N S, N S are north and south poles, ranged alternately, *a b c d* being a part of the continuous conductor which forms the armature of the machine. Let the conductor move in the direction of the large arrow; then, since lines of force coming from a N pole are being subtracted, and lines of force from a S pole added to the piece *a b c*, a current will flow

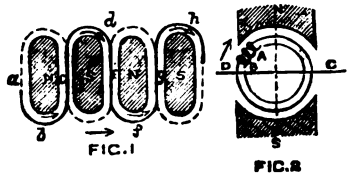


FIG. 1

FIG. 2

round that piece in the direction of the arrow at *b*. Similarly, as lines of force from a S pole are being subtracted, and lines from a N pole added to the piece *c d e*, a current will flow round that piece in the direction of the arrow at *d*, and so on for the other convolutions, all being in series, and the armature composed of several bands of the form shown laid on the top of each other. When the conductor reaches the position shown by the dotted lines, the direction of the current in all the convolutions will be reversed.

Fig. 2 is intended to show the fallacy of Mr. Nalder's conclusions regarding the direction in which the current flows in a Gramme machine. In the diagram, which is almost a *fac simile* of Mr. Nalder's, the machine rotates in the direction of the large arrow. A coil, with its poles marked A and B, is approaching the N pole, A being the approaching pole of the coil. Mr. Nalder concludes that since A is the approaching side of the coil, the current must flow so as to make A a north pole. This conclusion is erroneous. The approaching face of the coil will be a *south* pole, and the current will consequently flow in the opposite direction. To make this evident Mr. Nalder has only to consider that if the current flowed in the direction he assumes the ring would be magnetised by the current in such a way as to produce a N pole at D, and a S pole at C, which would *help* the motion of the machine. The current must flow so as to create a N pole in the ring at C and a S pole at D. This will oppose the motion of the machine, and is in accordance with the principle of the conservation of energy to which he refers.—Yours, &c., E.

---

## PRIMARY BATTERIES.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: In his letter under this heading in your last issue Mr. Ross asks a plain question, to which I will endeavour to give a plain answer, without any reference to the reasons which may have led to its being propounded, or to what has previously been stated in relation to the same question.

By the principle of the conservation of energy, the total work done by a current (or the calorific equivalent of such work when it appears as sensible and potential heat) must of necessity be equal to the electrical energy expended. Now, the electrical energy expended when a current of one ampere passes during one second under an electromotive force of one volt is 10 meg-ergs, or ·102 kilogrammètre, or ·737 foot-pound; and it may conveniently be expressed by the calorific equivalent of these values, viz., ·24 calorie (of Dulong). If, therefore, it were possible for a current of one ampere to pass through water under the E.M.F. of one volt (neglecting the E.M.F. requisite to overcome the resistance proper of the voltameter), it is clear that the energy stored in the gases evolved by the passage of the current during one second would be 10 meg-ergs, and might be expressed as ·24 calorie. But the quantity of hydrogen gas evolved by the passage through water of unit current during unit time is termed the electro-chemical equivalent of hydrogen; and, according to the (erroneous) assumption we have made, the electro-chemical equivalent of hydrogen would be that quantity which, in combining with oxygen, would evolve ·24 calorie. Since, as Mr. Ross has pointed out, one gram of hydrogen in combining with oxygen evolves 34,462 calories, the electro-chemical equivalent of hydrogen would thus be found by the proportion:—

34,462 : ·24 :: 1 gram : ·000007 gram.

This, according to Mr. Ross, is the value of the electro-chemical equivalent of hydrogen; whence it would follow that the electro-chemical equivalent of zinc must be ·000007 × 32·75 = ·000229 gram.

But it is not possible for a current to pass through water under the E.M.F. of one volt; since a back electromotive force of 1·49 volt is generated in the voltameter. Neglecting the E.M.F. requisite to overcome the resistance proper of the water interposed between the electrodes, the electrical energy expended in passing a current of one ampere through water during one second would be

·24 × 1·49 = ·3576 calorie.

In this fact is contained the answer to Mr. Ross's question. The fact that water requires a minimum E.M.F. of 1·49 volt to decompose it affects the electro-chemical equivalent of hydrogen, inasmuch as it implies that this equivalent must be the quantity in which is stored potential energy corresponding to ·3576 calorie (instead of ·24 calorie), *i.e.*, that this equivalent must be ·0000104 gram (instead of ·000007 gram). And since the electro-chemical equivalent of zinc is 32·75 multiplied by the electro-chemical equivalent of hydrogen, the same fact affects the electro-chemical equivalent of zinc by making it ·00034 (instead of ·000229 as above). And the same fact will consequently affect very considerably the consumption of zinc in a battery of, say, 60 cells.

(I observe that in my article on Zinc Primary Batteries the printer has substituted *grain* for *gram* three times on p. 249, and once in the fourth line of p. 250. Will readers please to correct the error?).

Mr. Ross is evidently under the impression that my state-

Digitized by Google

ment, as to the zinc consumed by the passage of a given current being the same in *any* cell, is in contradiction with his statement that Faraday showed that the quantities of zinc consumed in producing a given amount of electric energy, and decomposing a given quantity of water, may vary within wide limits. Both statements are quite correct, and $\left(\text{since } e = \frac{E}{n},\right)$ are implied in the formula $Zn = \frac{E\,C}{e \times 369}$ lb. given on p. 250.

I must remind Mr. Ross that *current* cannot be expressed in watts (volt-amperes).—Yours, &c.,

DESMOND G. FITZGERALD.

---

TO THE EDITOR OF THE ELECTRICIAN.

SIR: In reference to the note which appeared in your impression of the 9th inst., I may mention that I recommended the addition of methylated spirit to the solution in which the zinc plate is immersed over twenty years ago. My letter appeared in a journal then publishing under the title of *The Electrician*. —Yours, &c.,

A. RATTRAY.

Glasgow, February 26, 1884.

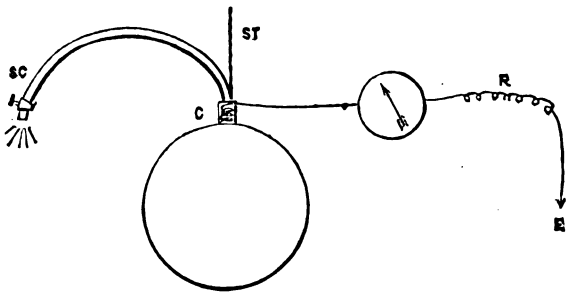
## RESISTANCE EXPRESSED AS A VELOCITY.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: A few months ago I was present at a lecture on the above subject. A charge, M, was given to an insulated spherical body of radius $r$; the sphere was then connected through a resistance, R, to earth. It was assumed to be collapsable, so



that as the charge leaked to earth the potential was kept constant by diminution of surface area. Then

$$\text{potential } V = \frac{M}{r},$$

$$\left.\begin{aligned}\text{and if loss of charge} &= dM\\ \text{and loss or decrease of radius} &= dr\end{aligned}\right\} \text{in time } dt,$$

$$\text{then } V = \frac{M - dM}{r - dr}.$$

By Ohm's law $dM = \frac{V}{R}dt$, and since $dr$ varies as time, $dr = v\,dt$, where $v$ is velocity with which radius decreases.

$$\therefore V = \frac{\frac{V}{R}dt}{v\,dt} = \frac{V}{Rv}.$$

$$\therefore R \text{ varies as } \frac{1}{v}.$$

I have succeeded in carrrying out this experiment as follows. Having obtained a thin india rubber bag, quite spherical when inflated, I coated it with extra fine plumbago. The mouth was stopped with a cork pierced with a glass tube, having a stopcock at the end capable of fine adjustment. The neck of the bag was firmly wired on to the cork, and the plumbago brushed over the wire to make connection. The bag, being inflated, was then suspended by a silken thread for insulation, and the wire on cork connected through galvanometer (a mirror) and resistance R to earth. A charge was given to the sphere by means of a Voss machine. A deflection at once ensued, falling very slowly. I at once began to let the air out at the stopcock at such a rate that the deflection was maintained constant, showing that the E.M.F. of the sphere was unaltered, and thus obtained a value for $v$. The plumbago kept a perfectly uniform surface, free from cracks. Since the charge resides only on the surface, the increased thickness of the coating did not matter. Of course the resistance of galvanometer was included in total R. By this means a table of velocities might be formulated for various resistances.—Yours, &c.,

Ealing, Feb. 26. SYDNEY T. DOBSON.

---

## PROFESSORS AYRTON AND PERRY'S FORMULÆ.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: In reply to your correspondent, "E. E. A.," let me state the case briefly to "ventilate" the subject.

Edison's system (Fig. 1) claims that every consumer has always the same potential, whereas Professors Ayrton and Perry show that neither this nor the constancy of any consumer's potential is secured while the others vary their consumption.

This is shown thus. Let

A $a$ = terminals at constant pressure V,
M $m$, N $n$ = two consumers,
$c$ = current from M to $m$,
$c'$ = ,, N to $n$,
$x$ = pressure between M and $m$,
$x'$ = ,, N and $n$,
A M = R, $ma = r$, AN = R', $na = r'$.

Then

$$x = V - (c + c')(R + r') - c(r - r'),$$

and

$$x' = V - (c + c')(R + r') - c'(R' - R).$$

"Hence for two consumers to have the same differences of potential they must use supplies of electricity bearing the same proportion to one another that the resistance from M to N does to that from $m$ to $n$."

Having the case of only two consumers, let useless mains be omitted (Fig. 2). Now, it is obvious that the total current

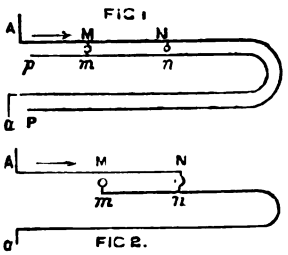


FIG 2.

$(c + c')$ passes first from A to M, where it divides thus: $c$ flows *viâ* M $m$ $n$, and $c'$ *viâ* M N $n$, at which latter point $n$, $c + c'$ recombine, and pass to negative terminal $a$. I therefore repeat my previous statement that the current $(c + c')$ supplying *both* consumers only traverses the resistances $R + r'$. As "E.E.A." "understands the subject" (Feb. 9) by his modifications

$$x = V - (c + c')(R' + r) - c'(r - r')$$

and

$$x' = V - (c + c')(R' + r') - c(R' - R)$$

this current in the first case traverses $m\,n$, and in the latter M N! Good by to Ohm and Kirchoff's laws and lamps too!

As to the leads M N and $m\,n$, we have seen that they do not take the whole current, but $c'$ and $c$ respectively. How it is possible to conceive that the only inference from this fact is that their resistance is *nil* I cannot imagine. Are there not *sometimes* conductor resistances in branch circuits besides lamps? In short, it is this inevitable resistance of mains which renders distribution difficult.

It only remains to be seen who has "certainly misunderstood the formulæ in more points than one."—Yours, &c.,

H. D. WILKINSON.

School Elect. Engineering, Hanover-square.

## OVERHEAD WIRES.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: Seeing that we had taken a fair share in the putting up of that network of wires which now overhangs the streets of our own northern city, we naturally felt taken aback by the trenchant vigour of your late leading article on the subject. We do not know whether you had London only in view when you censured telephone contractors generally for violating common sense and decency in constructing aerial lines regardless of everything but cheapness, but certainly even here there is much in the appearance of the wires to give colour to such an assertion. Yet the United Telephone Company, who own the local "exchange," and therefore most of the local wires, have adopted a system to which very little exception can be taken by any one. In erecting private lines, however, neither they nor we can do as we would like. Such lines do not radiate from a common centre; they begin everywhere and end anywhere, and, except in a few places, cannot be grouped into regular masses or carried by inconspicuous routes. Even if underground cables were laid to-morrow some of the stray wires, at present the most obnoxious, would need to remain as they are, for few firms could pay for the opening up of half a street or more for their private convenience. We are, however, in entire agreement with you as to the desirability of an immediate effort being made to put the great bulk of all mid-city wires underground. But we feel confident, also, that you will approve our statement that to enforce the entire abolition of overhead wires would do more harm than good. We will, with your permission, state why we object to so drastic a measure, why we think it unnecessary, and what we would propose to do to remedy the present admittedly intolerable state of things.

In the first place this sudden improvement off the face of the earth—or sky rather—of all the existing iron threads of commerce would greatly increase the cost of private telephony, although it is more than possible that a more moderate and natural adoption of the "underground" policy would prove in every way beneficial. By that we mean that it would pay a great telephone company to put down main cables along their principal routes, thus relieving roofs of hundreds of wires; but it would neither pay them nor the public to lay down wires in streets or districts where they had only a few customers. Then there would be a difficulty in deciding as to which companies were to be allowed to open the streets. Government, we are afraid, would not care to undertake the task of providing underground wires for all and sundry, and neither would the local authorities. Yet it would be impossible to grant the right to many, while to confer it on a few would be to place in the hands of that few the entire future of telephony. Even powerful companies coming forward after a time with new and improved instruments would hesitate to spend all their capital on cables which might not be required for many years, or probably would not be arranged to suit the demand which might spring up in unexpected quarters. The old companies, having, perhaps, paid up their cables before the new instruments appeared, would protect their monopoly by threats of a temporary lowering of prices against intending competitors, while these established companies themselves would have no motive to buy new instruments while the old lasted. They could easily quiet public demands by asserting that the new instruments were not an improvement, and this might well be true if such instruments were denied admission to that school of extended use in which all inventions are perfected. Then, from our point of view, it is naturally not unimportant that we and all those other independent telephone engineering firms should be sadly hampered, who, being first in the field, made the existence of wealthy and omnipotent companies possible by our early successful application of the telephone to the various wants of trade. Just now the public would suffer little from the loss of our efforts, because free competition is hindered by the refusal of the owners of existing telephone patents to supply the patented instruments unless along with other apparatus, as wires, batteries, &c., and then only on rental—an apparent evasion of their duty under the patent law to supply the reasonable demands of the public. But, sooner or later, the present semi-monopoly will end, and we (the various independent engineering firms) will then be the chief agents in introducing to the public the improved and cheaper appliances. Again, an extensive system of underground telephone wires would be an impediment in the way of the coming electric light wires; and, lastly, the accidents to pedestrians and vehicles which would be occasioned by a general upturning of streets, although less sensational, would be more real and numerous than any likely to occur through overhead wires during the next dozen years.

If, then, it be admitted that some overhead wires are necessary, it is also necessary to admit that those wires cannot be allowed to roam anywhere at their own sweet will or where chance directs. At present wires have to go this way and that, according as way-leave can be got, and before a line has been any time up it has to be awkwardly shifted at half-a-dozen of points, because owners of property change their minds. So that it is really not those who erect wires who are responsible for their unseemly appearance. If we all had liberty to go where we wished the total overhead mileage could be greatly reduced, a more orderly arrangement could be attempted, and the whole could be made much safer and less obtrusive. Now, although it is an admitted and frequently-applied axiom that the so-called rights of proprietors must bend to the necessities of social life and commerce, it would be too much to ask that everybody should have the right to do what he liked with his neighbour's roof. We therefore would propose the adoption of some such scheme as the following:—

1. That all overhead wires should pay a mileage tax of, say, about 20s. per mile per annum.

2. That this tax be used to pay good salaries to a local chief inspector of wires and a staff of assistants.

3. That this chief inspector be appointed by, and subject to, the local authorities.

4. That while in office he be sole arbiter of everything relating to the direction and safety of wires, subject only to appeal to local authority (or sheriff, if preferred).

5. That when a wire is to be erected, the firm who are to carry out the work—we will call them the engineers—would send to the chief inspector notice of their intention, and a plan of the route they would like to follow. The chief inspector would alter this plan, if necessary, and return it.

6. The engineers would then advise the landlord of, or agent for, the various properties on the route, and if any of them considered that they would be injured or annoyed by the wire, they could fill up, within so many days, the "objection form" sent them, and send it to the chief inspector, who would judge of its reasonableness (under right of appeal as described). Some method would need to be found of disposing of these appeals with little delay. After wire is up, similar complaints can be received, but not yielded to so readily as when sent in before wire is put up, unless in exceptional cases, as where proprietor was absent when first notice was sent.

7. The engineers' workmen would have no legal right to go on any roof or other property at any time, except when accompanied by an assistant-inspector to see that no damage was done, or, if done, repaired. It would probably be better that the person who accompanied them to the roof should be a slater or other tradesman, nominated by the landlord, but paid by the engineers at a rate not exceeding 1s. per roof for short visits, or 2s. per hour for longer periods. This tradesman would usually be the person who regularly kept the roof in repair, and he would need to reside or carry on business not more than a mile from the roof he had charge of. An hour after applying for his services at the appointed place, if he could not attend, the engineers' workmen could go without him. In the vast majority of cases engineers could obtain from the landlords free right of unaccompanied access by paying a lump sum annually, engaging to keep up the roof, or other private arrangement.

8. Engineers would require to carry out any alterations in their wire or fixtures which the inspectors might consider

Digitized by Google

necessary for the safety of the public, the convenience of property owners, or the seemly appearance of the streets.

9. It might also be provided that, where permission is given to any company to lay cables underground, they must undertake to rent wires alone if called upon. The arranging of a basis on which this could be satisfactorily done would be a somewhat delicate problem, however.

Such enactments as those we have described would hasten the putting underground of vast multitudes of wires, while those remaining would cease to be dangerous or unsightly. The money now lost in circuitous routes, in removing continual contacts, in shifting wires and bribing for way-leave, would all be saved to the engineers, and go far to cover the new charges and expenses, even if they were greater than we have proposed. We do not know how it is in England, but here, where formerly the granting of way-leave was so much a thing of course that the asking for it was a mere matter of courteous form, it will soon be impossible to get on to a roof at all. Linesmen have not always reported the damage they did, and frequently were not careful enough in ascertaining how many and which roofs were owned by the parties who gave them permissions, and so they made unauthorised fixtures on adjoining property. So they are blamed with all the damage they do and much more, and landlords have been known to ask, and even receive, as much as £1 per fixture per year for way-leave. Of course, if this were general we might bid farewell to cheap telephony. We have already trespassed enormously on your space, so we will respectfully leave our suggestions to your consideration and experience, and that of your readers.—Yours, &c., ANDERSON AND MUNRO.

Glasgow, February, 1884.

## RUHMKORFF COILS.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: Can you kindly tell me where to find an account of the experiments made on the Ruhmkorff coil by Du Moncel in 1859? This information would much oblige.—Yours, &c.,

Stalybridge, Feb. 26, 1884. R. C. JACKSON.

## THE GAULARD-GIBBS SYSTEM.

TO THE EDITOR OF THE ELECTRICIAN.

[The following correspondence on this subject, in addition to that published in our last issue, has passed between The National Company for the Distribution of Electricity by Secondary Generators and Sir Charles Bright.—ED. *E.*]

The National Company for the Distribution of Electricity by Secondary Generators, Limited.
18, Warwick-street, Regent-street, W.,
London, February 22nd, 1884.

To Sir Charles Bright,
Honorary President of the English Section of the Société Internationale des Electriciens,
31, Golden-square, W.

Sir: In reply to your letter of the 21st instant, we beg to say, in explanation of our having addressed you, that we thought the expressions of interest in our system elicited at the meeting in Paris on the 6th instant, when you were present and offered some remarks upon the explanations given by M. Gaulard, as well as your own previous researches, would have sufficiently interested you in the results we have obtained to have caused you to wish to verify them.

You can hardly seriously contend that your printed specification of the 22nd October, 1878, to which you refer, entitles you to say, "I invented the system of distributing electricity by secondary generators which you employ." Your invention, which received provisional protection only, is not sufficiently described in the said specification to enable any practical application of it to be made, and anything therein contained is undoubtedly public property.

Having seen our correspondence, including your letter dated only yesterday, in print to-day, without any previous intimation to us, we ask you to give to this letter the same publicity, otherwise we shall, in self-protection, print it ourselves, with the full text of the provisional specification to which you have referred.—Yours, &c., L. Gaulard
J. Dixon Gibbs.

31, Golden-square, London, W.,
26th February, 1884.

Messrs. Gaulard and Gibbs,
18, Warwick-street, W.

Gentlemen: I beg to acknowledge the receipt of your letter of the 22nd inst.

I certainly do contend that the use of induction apparatus as a means of distributing electricity for lighting purposes is sufficiently described in my specification of 1878, No. 4,212; and that any practical electrician could from it construct a working system with well-known generators and induction apparatus.

I fail to discover anything but well-known appliances of this kind in your patent of 1882, No. 4,362, in which you claim the system of distributing electricity by secondary generators.

Still, I am quite ready to modify my views if you will have the kindness to indicate to me the features which you claim to be new in your patent.

Regarding your objection to publication, allow me to remind you that your letter of the 18th instant (referred to in another letter accompanying it as a "formal communication") was addressed to me officially, and was obviously intended for publication, now or hereafter.—Yours faithfully,

Charles T. Bright.

18, Warwick-street, Regent-street, W.
February 26, 1884.

Sir Charles T. Bright,
31, Golden-square, W.

Sir: In reply to your letter of this date we beg to say that if you had accepted our invitation you might have satisfied yourself that we are doing what neither you nor any one else has ever done. The patent to which you refer is only one of a series. We do not, however, feel called upon to discuss the value of our inventions; you may rest assured that we have been advised by competent authorities, and are fully protected.

We remain, sir,
Your obedient servants,
Gaulard,
J. Dixon Gibbs.

31, Golden-square, London, W.,
28th February, 1884.

Messrs. Gaulard and Gibbs,
18, Warwick-street, W.

Gentlemen: I am in receipt of your favour of the 26th inst.

You say that your patent which I have called in question is "only one of a series," but it is the one in which you make a positive claim for "the employment of an alternating current of high tension for the generation on an unlimited number of secondary generators of induced currents."

I repeat that this is absolutely forestalled by my specification of 1878, No. 4,212; but even if this were not the case, I now refer you to a later specification of 1878, No. 4,611, in which the use of alternating currents actuating secondary or induction coils at the various lighting points (in the same manner as in my prior specification of 1878 and yours of 1882) is described.

In this specification you will also find that your "bundle or rope" of wires on the induction coils is included, with a similar provision for "grouping" them, either for quantity or intensity, the word "cable" being employed, instead of your word "rope."

Another point in your patent is the separation of the insulated wire into several bobbins on the same core. Now, this method of winding coils was described and illustrated in the patent of Mr. Edward Bright and myself, dated 21st October, 1852.

Poggendorf, Ruhmkorff, Foucault, and others re-invented it afterwards, and it has been very generally used in constructing induction coils. The late Count du Moncel, in his "Exposé des Applications de l'Electricité" (Ed. 1873, pp. 241-3), summed

Digitized by Google

up the claims to priority, which he accorded to my brother and myself.

The only two other remaining features of your patent are the surrounding of the insulated wires of the induction coil with cylinders of iron between the layers of wire, and the arranging "several columns of bobbins" vertically "in parallel rows." Both of these arrangements are fully described in the patent of myself and my brother (No. 2,103, of 1855) referring to the induction coils shown in Figs. 9, 10, and 11 of the drawings.

From the above it appears to me that your advisers have not been sufficiently acquainted with electrical patents, or else you would not have re-patented so many old inventions.

Yours faithfully,

CHARLES T. BRIGHT.

## TELEGRAPH CONSTRUCTION AND MAINTENANCE COMPANY (LIMITED).

Sir Daniel Gooch, Bart., M.P., presided over the twentieth ordinary general meeting of the members of this Company, which was held at the offices, 38, Old Broad-street, on Tuesday last.

The SECRETARY (Mr. E. Dickens) read the notice convening the meeting and the minutes of the last meeting.

The CHAIRMAN: I must congratulate you on the steady prosperity of your Company, and on the fact that we are able again at this meeting to declare a dividend of 20 per cent. That, I hope, will be a satisfactory dividend to you all [hear, hear]. The accounts for the year show a net profit of £93,334 16s., after charging the interest on the debentures. To this sum must be added £63,015 5s. 9d. brought forward from last year, making a total of £156,350 1s. 9d. From this amount is deducted the interim dividend of 5 per cent., paid July 24, 1883, amounting to £22,410, leaving £133,940 1s. 9d. to be dealt with. Of this sum the directors propose to distribute a dividend of £1 16s. per share, absorbing £67,230, being at the rate of 15 per cent., and making, with the amount already paid, a total dividend for the year of £2 8s. per share, free of income-tax, leaving £66,710 1s. 9d. to be carried forward to the next account. The work performed during last year I may state shortly is as follows:—A cable, 965 miles in length (manufactured in 1882), was laid early in the year between Hong Kong and Shanghai for the Eastern Extension Telegraph Company; a cable, 1,402 miles in length (a large portion of which was manufactured in 1882), has been laid in the Red Sea, between Suez and Aden, for the Eastern Telegraph Company. This was completed in the month of April. Cables of the total length of 1,369 miles have been manufactured and laid for the Great Northern Telegraph Company of Copenhagen, between Shanghai, in China, and Nagasaki, in Japan, and between the latter port and the Russian Settlement of Vladivostock. These lines were completed in the month of September. The Brazilian Submarine Telegraph Company's cable, between St. Vincent, Cape de Verds, and Pernambuco, Brazil, which was broken in September in the neighbourhood of the equator in a depth of 1,900 fathoms, has been repaired, a length of about 80 miles of new cable having been spliced in. I may say that that was considered rather a remarkable feature, and your staff have gained great credit in having been able to accomplish that work. The cable was repaired in a very short time and the work was successfully done, and not only the Brazilian Company themselves are very highly pleased with the way the works were done, but I think we are also, and you ought to be very pleased with our staff. As the cable was down ten years it will be satisfactory to those holding cable property to know that it was picked up in perfect condition, except in the portion where the break occurred. The break was supposed to be through some ship's anchor, or consequent on some volcanic action, but the other part of the cable was as bright as it was on the day when it was laid down. A length of 800 miles of cable has been manufactured for the Eastern Extension Telegraph Company, to connect Saigon, in Cochin China, with Tonquin. Since this report was printed the cable has been completed, and the French are now utilising it. It was principally for the French. A length of 847 miles of cable has been manufactured for the Eastern Extension Telegraph Company for the renewal of certain portions of their lines in the China Sea, and between Java and Australia, and for the replacing of the Sunda Strait cable. The Sunda Strait cable has been completed since this report was prepared, and the ships are now gone towards Australia to complete repairs there, which I hope they will do in a short time. Various short lengths of cable have also been manufactured for other companies during the year in addition to those I have already mentioned. We have entered into a contract recently with the Brazilian Company to duplicate their cable for the whole length, and the work is in progress now. The ships will sail next month to lay the first portion between Madeira and St. Vincent, and the other will follow in due course. The accounts speak for themselves. I shall be very glad to give any information and details with regard to them that any shareholder may require, or upon any other subject. I hope, if any shareholder wishes for any further information with regard to the Company, he will ask questions, and I will supply it if I can. I now move—"That the report and the accounts of the directors to the 31st December, 1883, submitted to this meeting be, and the same are hereby received and adopted, and that a dividend of 36s. per share, in addition to the 12s. per share interim dividend paid on June 30, 1883, be paid on all shares of the Company for the year ended 31st December, 1883, and that such dividend be paid free of income-tax."

Mr. PHILIP RAWSON seconded the motion.

Mr. LEWIS asked the mode in which the 6 per cent. debentures were allotted. Considering that the Company was owed £319,000, in round figures, that it had £110,000 cash in hand, and a reserve fund of £50,000, it seemed very surprising that, holding such a position, the Company should have to pay 6 per cent. He thought the amount should have been obtained at 5 per cent. [A voice: 4 per cent.] or 4½ per cent. He applied in common with some other shareholders for this "good thing," and got nothing, but that did not interfere with his argument. In these days when directors were so secret he supposed it might be considered a piece of impertinence if he asked how much of the amount was allotted to the several directors, and whether a list of the several persons to whom the amounts were allotted could be furnished to the shareholders with the amount which each obtained.

A SHAREHOLDER asked whether it was expected that the work referred to for the Brazilian Submarine Company would be finished this year?

The CHAIRMAN: Yes.

Mr. THORPE believed that at the last half-yearly meeting some of the shareholders made some observations as to electric lighting, and he believed that the chairman said that that matter would not be lost sight of by the directors. Considering that electric lighting was at any rate one of the great topics of the day, and as he supposed that there would sooner or later be an end to the laying of submarine cables—[The chairman: I hope not]. He (Mr. Thorpe) hoped not also, but still there must be a limit at some time or other, and that being so, he would like to know whether the directors saw their way to utilising the resources of the Company with regard to electric lighting.

Mr. COOPER said that he was a small shareholder, but he had £100 debentures allotted to him.

The CHAIRMAN: As to these 6 per cent. debentures and the secresy that the honourable proprietor thinks the directors observe, I think that if the accounts of a trading company were not kept secret to some extent, it would not be to the interest of the shareholders. I think you will consider a 20 per cent. dividend a satisfactory result, and that you will be satisfied rather with the result than going into details. I could not retain this position for an hour if the Company were to be managed by the shareholders. The 6 per cent. debentures were issued with the approbation and consent, to a certain extent, of the shareholders ten years ago, and they were renewed when they fell due at the end of last year. The applications on this occasion, instead of being, as on the former occasion, not sufficient to get the debentures issued—that is, the applications did not equal the amount, and we had to get them taken up afterwards by others—amounted on this occasion to over £800,000 for the £150,000. The effect of that was that we were obliged to act on some principle in alloting these debentures. We had applications from those who held five or six shares, and who had comparatively no stake in the Company, and the principle that actuated us was to allot those debentures amongst those who, we thought, would hold them, and not make a market speculation of them. The responsibility resting with us, the work must also rest with us. It would not be consistent with our duty to print and publish a list of our debenture holders any more than it would be to publish a list of our shareholders, and I cannot be a party to publishing such a list. The directors acted on their own responsibility, and I think if you cannot trust the Board to do that you should elect some one else. I for one feel that the directors ought to be trusted with regard to the alloting of £150,000 debentures. They were allotted only to those who were shareholders of the Company—not to those who were not shareholders. It was impossible for men with two or three shares to get these debentures. I believe in one case the holder of one share asked for £18,000 of them. We acted as we did for the interests of the Company.

Mr. LEWIS thought the chairman might answer the question why 6 per cent. was given.

The CHAIRMAN: I told you that that was because we agreed to do so. The shareholders found that it was necessary to give 6 per cent. on the previous occasion, and I do not think that 6 per cent. is too high a rate, considering that we are a trading company of a speculative character. As to the electric lighting, we got powers last year from Parliament to enable us to extend our work in that direction. We also got a concession to light a portion of St. James's, in connection with the Edison Company. It was done by agreement with the Edison Company. They got powers, and we agreed to join with them. We thought that each of us could carry out our own portion, but the Board of Trade did not agree to that division of the work. We are not losing sight of this matter, but it is a question, particularly as regards St. James's parish, or any portion of London in fact, that requires a great deal of care, and we have no experience in connection with such a large extent of lighting. We have arranged with the Great Western Railway Company to light their Paddington Station throughout—the offices, platform, and the whole of the station. That will be a very large extent of lighting, and I hope it will give us some useful information. It is not a very large speculation, but it will be a guide for us before we go too deeply into the matter.

Mr. JOHN NEWTON thought that the directors ought not to consider that there was any insinuation in the criticisim that had been made with respect to the issue of the debentures, and it was wrong, he contended, for the directors to assume such a position. He held one share in the Company, and there was very good reason why he held only one share. A great deal of his money was invested in telegraph companies, and therefore he held one share in this Company in order to know how matters were proceeding, as he got from the report of the directors a great deal more information as to the cables that were laid than he obtained from any telegraph companies that he was a shareholder in. He applied for

Digitized by Google

£200 debentures because he had held that amount from the commencement. As to making a market, he had never sold one of the bonds, but till he had no right to expect that he would get his application renewed. He objected, however, to what the chairman had said, that because they were issued at 6 per cent. ten years ago, they should have been issued now at the same rate. Telegraph companies were always issuing debentures at 6 per cent. in the earlier period mentioned, but now they got them out at 4 per cent. Besides that there was a change in the money market now as compared with ten years ago. He maintained that it was the bounden duty of the directors to issue debentures at the best possible rate for the interests of the Company, because as it was the large shareholders were taking the plums while the small ones were getting the crumbs. He thought the position of the Company was so magnificent that if they had offered the debentures at 4 or 5 per cent. they would have been taken up and the credit of the Company would have appeared higher than it would now with a balance-sheet showing that debentures had been issued at 6 per cent.

The CHAIRMAN put the motion, and declared it carried unanimously.

On the motion of Sir G. ELLIOT, Bart., M.P., seconded by Mr. PHILIP RAWSON, Sir Daniel Gooch was re-elected a director of the Company, and subsequently on the motion of the CHAIRMAN, seconded by Mr. RAWSON, Sir Thomas Fairbairn was also re-elected to his seat at the Board.

Mr. John Gane and Mr. James Glegg were re-appointed auditors of the Company, at a remuneration of 150gs. each.

A vote of thanks to the chairman terminated the proceedings.

## THE INDIA RUBBER, GUTTA PERCHA, AND TELEGRAPH WORKS COMPANY (LIMITED).

The twentieth ordinary general meeting of the shareholders of this Company was held at the Cannon-street Hotel, on Tuesday last, under the presidency of Mr. George Henderson.

The SECRETARY (Mr. W. J. Tyler) having read the notice convening the meeting,

The CHAIRMAN said: Gentlemen, before I proceed to move the resolution as to the dividend, allow me to congratulate you on the Company's approaching majority. We are in our twenty-first year, and though we have had our changes of fortune, we hope we have entered on a period of reasonable prosperity now. Some of our shareholders appear to be dissatisfied that we are distributing among them less than at this time last year. For my part, I do not feel in a mood to apologise for a 15 per cent. dividend, but if any have bought their shares expecting, as a matter of course, a constant bonus as well as a good dividend, they will be disappointed. Furthermore, last year we felt bound to warn you not to count on this bonus. I will read you what Mr. Gray said at the last meeting in February. He said: "I want to warn the shareholders that, although we will do everything we possibly can for the success of the Company in future, last year was an exceptional year. Do not, I beg of you, get it into your minds that it is going to be yearly repeated I do not mean to say that it never will be repeated—I hope it will be, and will be often—but I do not wish that any shareholder should have any anticipation that it is anything like what will usually be the case. I do not wish to depreciate the property—you can well understand that; but, at the same time, I do not wish to disappoint the shareholders." A shareholder said at the same meeting: "You have given us not only a good dividend but a bonus. We may therefore, without going very carefully into the matter, consider that the profits are represented by the dividend, and that the reserve carried over and the bonus have been derived from these extraneous profits, which are probably only to be made in this year, and not in every year. I think it is very advisable that this should be borne in mind by the shareholders, because when a dividend of 25 per cent. is paid, they are very apt to think they ought to get the same thing again. I for one think this is probably a peculiar case, and that we shall not for some time have such a dividend again. I hope it will come again, but I for one, and I trust many others, consider that we are well paid, and receive a good remuneration for the money we have invested here, if we get the dividend apart from a bonus in future years." When we last met you, six months ago, we were beginning the manufacture of about 2,000 miles of cable, to connect Spain with the Canary Islands and Senegal. This has been completed. As to the cable between Spain and the Canary Islands, the whole has been nearly laid. With the unusual difficulties connected with the preliminary soundings, the work of laying all this cable has proved one of considerable difficulty, owing to the great and sudden variations in the depth of water, and the rough and rocky nature of the bed of the sea. As to the cable from the Canary Islands to Senegal, it has taken longer than we anticipated, because of the necessary arrangements connected with the laying of it that had to be made; but we expect this will be completed shortly. Our general manager, Mr. Gray, has just returned from a visit to the United States, to look up our American friends, and to make new ones, with a view to increase our business. I regret to say that our colleague, Dr. Beattie, has been removed by death since this year opened. His health had been failing for some months, but we did not expect the end was so near. He had been one of us for twenty years, and his death makes the first breach in our number. His successor, Mr. Scott, who has long been known to us as a shareholder, will, we feel sure, devote his best energies to promote the Company's interests. He retires from the auditorship, and I suggest for the consideration of the shareholders whether a second auditor is necessary. The Articles do not require this, and you will probably think with me that your interests in the matter are safe in the hands of Mr. Weise, a partner in the firm of Messrs. Turquand, Youngs, Weise, and Bishop. However, we leave this with you, as it is entirely for you to consider and decide. I am glad to tell you that we have begun this year's business satisfactorily. This meeting will be resolved into an extraordinary meeting for the consideration of our Bill in Parliament. Meanwhile I will move, "That the report and accounts now presented be received and adopted, and that a dividend of £1 per share (tax free), payable on the 27th inst., be now declared." When this has been seconded, I shall be glad to hear any observation that the shareholders may desire to make.

Mr. S. W. SILVER: I beg to second the chairman's motion.

Mr. VEARY said he would be glad to put a question as to the item stock-in-trade, which he saw standing at £89,000 odd. He would like to be informed how much of that sum was put down for the Senegal cable, and he would further like to be told how the Senegal cable would be paid for—whether it was to be paid for in cash or securities, and if so in what securities. He presumed that the contract dealt with that matter. With regard to the item of the reserve fund on the other side of the account, it was put down at £200,000, and no doubt that was a very satisfactory amount, but he wished to ask in what way it was invested—whether it was invested in securities which would not be dealt with in the same way as property or ships, whether it was part of the item on the other side of the accounts standing at £437,000, or whether it was treated as a reserve fund and was separate?

Dr. SMALL having addressed the meeting,

Mr. R. W. SMITH observed that the profits of the Company were stated at £48,000, and he wished to know whether that was derived from the ordinary business of the Company, or whether it was partly for cable work?

Mr. M'NAUGHT said he would like to know whether the contracts the Company now had with Governments were taken on such favourable terms as to promise them as good profits in the future as they had had in the past, or whether the Company took them on less favourable terms which would give them less profits than they were wont to derive?

The CHAIRMAN: With regard to the first question—how much of the item stock-in-trade is taken for the Senegal cable, I must respectfully but firmly decline to answer it. We are a trading company, and I cannot give such information [hear, hear]. The second question is, how will the Senegal cable be paid for, in cash or in securities? Mostly cash—partly cash partly securities.

Mr. VEARY: More than half cash?

The CHAIRMAN: Yes. Then the next question was—how is the reserve fund invested? I think if you look at the accounts they show that we have no capital for our business at all if we did not use the reserve fund.

Mr. VEARY: Why not put it in the £437,000?

The CHAIRMAN: We must put it in the reserve fund, as it is.

Mr. VEARY: Why is it treated separately?

The CHAIRMAN: That is the only way in which we have a right to put it. With respect to Dr. Small's question we have had to add considerably to the property at Silvertown, and to do something to the works at Persan-Beaumont, and the money has been spent there. I cannot answer Mr. Smith's question—to give the items making up our profits. As a trading company we cannot do that. We never have done it. But as to Mr. M'Naught's question, we have a great deal more competition than we had, and we have to take lower profits, most certainly. We get all we can, but we have competition, and we must meet that competition. I think I have answered all the questions which have been put; and, if there is no other observation, I will put the resolution, as we have to go to an extraordinary meeting afterwards.

He then put the motion and declared it carried unanimously.

Mr. SILVER: It now devolves upon me to move the re-election of our chairman, and in doing so I cannot but assure you that his attention is unceasing to the interests of the Company; and therefore I move this resolution with great pleasure.

Mr. NEIL BANNATYNE: I have very great pleasure in seconding Mr. Silver's motion, and I am sure that I can add my testimony to the invaluable services which our chairman—ever since I have been connected with the Company—has rendered to us. We have a great many of our shareholders who have stuck to us for a great number of years—for eight or ten years at least, and I cannot resist the temptation of just adding a few words to show the present position of the shareholders for a length of time as compared with what it was seven or eight years ago, when we reconstituted the capital account. I do not know whether any of the shareholders present will remember that at the end of 1877 our £50 shares were somewhat between £19 and £20. For every £50 share, in the spring of the following year, when we altered the accounts, we gave the shareholders three £10 shares, amounting to £30. We also gave each shareholder for every new £10 share one share in the West Coast of America Telegraph Company. The two together were at that time, according to the market price, somewhat between £19 and £20. But the present market value of these shares is as follows:—The three India Rubber Company's shares are worth £23 10s. each, amounting to £70 10s., and those shareholders who have kept the West Coast of America Company's shares see that the market value is £6, so that you have to add three sixes to the other amount—that is, £18, making together the market value of £88 10s., for what was at the time I speak of quoted at £19 to £20. I think that is a result which is very satisfactory, and, although the shares have recently fallen, I have in this calculation taken them at their present prices. When the price of the India Rubber shares was £30 the result of course was very much better. I will end now by only saying that, after the services of our invaluable manager, nothing has contributed more to this result than the continued assiduity of the chairman and the value of the services which he has rendered to the Company. I have therefore very great pleasure in seconding Mr. Silver's resolution.

Digitized by Google

The motion was carried unanimously.

The CHAIRMAN: I beg to thank you most cordially for my re-election. I think that my friends on the right and left hand have said more than they ought to have done; but I will do all I can for you.

Mr. H. A. SILVER moved the re-election of Mr. Weise as auditor for the current year at a fee of 30 guineas.

Mr. J. O. ANSON seconded the motion.

The CHAIRMAN put it to the meeting, observing: I presume that means that he should be sole auditor. Is that so?

Mr. H. A. SILVER said that that was his intention.

Dr. SMALL thought in the state of the Company's accounts and the way in which they were progressing that there ought to be two auditors. He did not think that another auditor would be much expense to the Company, and it was right that the shareholders' interests should be fairly represented by there being two auditors.

The CHAIRMAN: It is entirely for the body of the shareholders. I threw out the suggestion from what I know of the working, and I thought that one auditor was sufficient, but I repeat it is entirely for the body of the shareholders.

DR. SMALL moved that another auditor be appointed, adding that he had been connected with the Company for ten years, and that he fully appreciated the remarks which Mr. Bannatyne had made.

Mr. ANSON suggested, as the seconder of the resolution, that they should have the firm of Turquand, Youngs, and Co. He quite fell in with the views of Dr. Small.

Mr. S. W. SILVER said he thought that practically the one auditor did the work. The shareholders' auditor merely came in and added his name, endorsing what the accountant had done.

Dr. SMALL thought that the feeling of the meeting should be taken on the point whether there should be one or two auditors.

Mr. GEO. MORTON thought that Mr. Silver had not given a good recommendation to Mr. Scott, who had been appointed a director.

Mr. SCOTT, as an old auditor, stated that he had carefully gone through the whole of the accounts. He had fully examined all the books, and had asked thousands of questions, but when he had finished he could only say he found the work thoroughly done by Mr. Weise.

Mr. GEO. MORTON said he was very glad to hear Mr. Scott give a better account than Mr. Silver had of the services which he had rendered as auditor.

Dr. SMALL observed that Mr. Scott had said he had put thousands of questions to Mr. Weise, and that showed the necessity for a second auditor.

Mr. SCOTT: All my questions were answered.

The CHAIRMAN: I know that Mr. Scott did his work thoroughly, but the whole of the work is done by the clerks or the assistants of Messrs. Turquand, Youngs, and Co., and the accounts are prepared both for Mr. Weise and Mr. Scott.

Mr. ANSON, in answer to a question, stated that he had not seconded Dr. Small's amendment, but he threw out the suggestion that it should be the firm who should audit their accounts.

The motion was then carried.

The SECRETARY then read the notice convening the extraordinary meeting.

The CHAIRMAN: I will call on the solicitor, Mr. Hutchins, to give an explanation of the Bill.

The SOLICITOR: The real reason for wanting the assistance of Parliament arises from the peculiar wording of the old Memorandum of Association, and your Memorandum of Association cannot be altered by you without the authority of Parliament. I may say the same difficulty occurred to the Telegraph Construction Company, and last year they went to Parliament to get an Act to enable them to do various things which it was very doubtful whether they could do under their old Memorandum. In 1864, when both these companies were established, the thoughts of every one were turned to telegraph works and telegraphic purposes. They did not know then into how many branches the application of electricity and magnetism would diverge, and the great object in each of the Memorandums of Association of the companies was to take power "to purchase and manufacture wires, hemp, and all other materials, articles, and things in any way connected with or incident to telegraph purposes." We have always found since the great development of electricity that we were hampered by these words—"for telegraph purposes." For instance, the question arose, which was very much discussed by the Post Office and the various telephone companies, as to whether telephone purposes were included in telegraph purposes—the telegraph meaning far writing, the telephone far sounding. Then, again, we have electric lighting, which is another thing. It is difficult to say that a wire producing the light at a great distance from a battery can be properly called telegraphic. It is very difficult to bring that matter into the words "telegraph purposes." But besides all these phases of our manufacture, we do not know what is going to happen in the development of all these things—electricity, magnetism, and galvanism—and the works are laid out in such a way that they can be applied to a great many purposes of the sort not thought of in 1864. It has therefore been thought advisable that we should go to Parliament to ask for liberty to alter our Memorandum of Association, so as to give us the very widest power of turning our machinery, works, and staff to any profitable purpose that may be found open to us connected with electricity, magnetism, or galvanism, and the making of all kinds of things to which they may be applied. We shall have the Bill read to you in a moment, and I think the only point I need notice in the Bill is the question of foreign works. It was always a doubt in our Memorandum whether the original directors ought to have gone in for the works in France, and at one time there was a committee appointed for selling these works. There were at that time also works in Belgium as well as in France, but those in Belgium were sold, the works in France being kept reluctantly, because there was no purchaser. Those works, however, are very much improved, and a great deal of valuable business is going on there, and we wish to make it perfectly clear, to prevent any doubt arising hereafter, in the Memorandum that these works are in the possession of the Company, and may be treated and used for your benefit.

The Bill was then read *in extenso*.

The CHAIRMAN: I beg to move "That the sanction of the India Rubber, Gutta Percha, and Telegraph Works Company (Limited) be given to the Bill introduced into the present Session of Parliament, intituled, 'An Act for defining or extending the powers of the India Rubber, Gutta Percha, and Telegraph Works Company (Limited), and for other purposes,' subject to such alterations, additions, and variations as Parliament may think fit to make therein."

Mr. S. W. SILVER: I beg to second that.

The CHAIRMAN put the motion, and it was carried unanimously.

On the motion of Mr. TREBLE, seconded by Mr. VEARY, a vote of thanks was passed to the Chairman, who briefly acknowledged the compliment. The proceedings then terminated.

## THE ANGLO-AMERICAN BRUSH ELECTRIC LIGHT CORPORATION (LIMITED).

An extraordinary general meeting of this Company was held on Wednesday, at the Cannon-street Hotel, Lord Thurlow in the chair.

Mr. GARCKE (the secretary) having read the notice convening the meeting,

The CHAIRMAN said: Gentlemen, it will not be necessary for me to detain you at any length this afternoon. You are all aware of the reason for which we have met here to-day. Our meeting is purely formal and statutory to confirm the special resolution which you passed unanimously at the general meeting which was held at this hotel three weeks ago. I think I may congratulate you on the unanimity with which the resolution was passed and has been received both by the great body of shareholders themselves and by the public out of doors. I think it will be quite unnecessary for me to dwell at any length upon it to-day. You fully understand its object, and I will only ask you to be so kind as to confirm it, as it is necessary that it should be confirmed in this meeting to-day to conform to law. I therefore move the confirmation of the following resolution:—"That the capital of the Corporation, which now consists of £800,000, divided into 80,000 shares of £10 each, of which 13,701 shares have been issued, and are fully paid, and 26,999 shares have been issued, and have £8 per share paid, or called up thereon, be reduced to £400,000, divided into 80,000 shares of £5 each, and that such reduction be effected by cancelling paid-up capital, which has been lost or is unrepresented by available assets, to the extent of £5 per share, upon each of the 40,700 shares which have been issued, and by reducing the nominal amount of all the unissued shares from £10 to £5."

Mr. J. S. SELLON: I beg to second the resolution which has been put before you by the right hon. chairman, and it is certainly not necessary for me to say more than that I second it.

The motion was carried unanimously.

On the motion of Mr. Offor, a vote of thanks to the chairman terminated the proceedings.

## METROPOLITAN (BRUSH) ELECTRIC LIGHT AND POWER COMPANY.

An extraordinary general meeting of the shareholders in this Company was held at the City Terminus Hotel, Cannon-street, on Thursday, the 28th February, Mr. J. H. Borrer presiding.

The SECRETARY (Mr. Robert Wilson) having read the notice calling the meeting and the minutes of the previous meeting,

Mr. A. PEEBLES said that in rising to move the first resolution it was not his intention to detain the shareholders by making any remarks further than to state that the liquidators were quite prepared to enter into any undertaking whatever which the shareholders might desire, to the effect that there should be no further call upon them [hear, hear] unless there was an extraordinary general meeting to specially sanction it. But he might state that there was no prospect that there was likely to be any necessity for a call. They had in the bank the last time the books were examined more than amply sufficient to pay every cost that would arise, and make a considerable return on their shares. He concluded by moving—"That the following resolution, passed at the extraordinary general meeting held on the 12th February, 1884, be, and the same is hereby confirmed: 'That in the opinion of this meeting it is desirable that the Company should be wound up, and that the same be accordingly wound up voluntarily.'"

A SHAREHOLDER having seconded the motion,

Mr. TOTTENHAM, without wishing to trouble the meeting with many remarks, desired it to be understood first of all that he was one of the largest shareholders in the room, and not to be looked upon as a director, a position which he supposed he would cease to hold from that day. But, as a very large shareholder, he was naturally anxious that the shareholders should be protected as far as possible from certain calls that might be made upon them. Now Mr. Peebles, he noticed, was very properly doubtful about the question of calls——

Mr. PEEBLES: I beg your pardon.

Mr. TOTTENHAM thought Mr. Peebles had expressed himself in a

Digitized by Google

doubtful tone at all events, and he had considerable experience in such matters. He (the speaker) was somewhat more than doubtful, and he gathered from the expression of opinion of many friends of his that they, too, were extremely doubtful about the matter. [Hear, hear.] As directors of the Company he and his colleagues felt that it was their paramount duty to put the position of matters as clearly before the shareholders as possible. They carefully avoided any long statement of facts because, being men of business, it was presumed that shareholders would know as much about the subject as they did. The circular last sent out to them was to his mind sufficiently explicit, and he thought most of the shareholders were provided with one. They all knew what liquidators were, and the extent to which calls might be made under such circumstances as the Company was placed in, and the manner in which they were made was most embarrassing to the shareholders. He sincerely trusted that they would not be subjected to any such calls, but he could not help feeling (and he was sure most of them would agree with him) that they would be liable to calls until this Company was finally wound up if the recommendations of the shareholders' committee were adopted. They all knew that some recent cases in London—that, for instance, in connection with the Alexandra Palace and others—cost very large sums of money, and he had heard that there were a considerable number of things in the present case that would be likely to make it a very costly suit. On the part of Mr. Borrer and himself he repudiated the idea that they were playing into the hands of the promoters. Mr. Borrer did not know a single promoter even by sight, and as for him (Mr. Tottenham) he had the pleasure of knowing only one. The directors had a very large number of proxies, and he felt confident the shareholders would consider that they were justified in making some very strong remarks in favour of their programme. They were supported by a very large number of shareholders, and some of them the most influential in the Company. He did not know what the chairman would do, but his impression was that if the meeting was largely in favour of adopting the resolution that they would not trouble them to go to a poll.

A SHAREHOLDER agreed with the Chairman of the Committee so far as the liquidation was concerned, but as a protection against undue expenses he would make the remuneration of the liquidators dependent on the result [hear, hear]. In regard to the continued printing and circularising that were going on, he would like to ask who paid for that, because he, as a shareholder, objected to have to pay any portion of it. The directors had already lost them upwards of £14,000, and they ought to have thought it a shame almost after the unanimous opinion of last meeting to hold their seats. They had wasted a fortnight that might have been occupied in commencing the suit and disposing of the provisional orders.

Admiral INGLEFIELD said that practically, immediately after the adjournment of the last meeting, the committee made an offer to the Board to take over the affairs of the Company, to put an end to expense, and commence the duties which the meeting had assigned to them. To that application they received a refusal, and, consequently, the Company had been put to the expense of keeping the Board and the staff on full pay up to the present and waiting for their decision. There was an expense of about £8,000 a year going on to keep up the staff, &c., and there was no sort of return for it. For the last fortnight they might have been working for their interests, and doing their best to dispose of the provisional orders, but they had not the opportunity. As to the payment of the liquidators, they would claim only what it was customary to give to liquidators, and that would be left entirely to the shareholders to be decided at a general meeting.

The CHAIRMAN said it was true that the committee offered to relieve the Board of their duties after the last meeting, but it was because they felt it was no less than their duty to propose and lay before the shareholders some scheme for the reduction of the capital that they could not assent to the proposal. He did not think that the provisional orders could be disposed of so easily as was imagined. The Board of Trade had emphatically said that they did not see their way to admit a transfer. He thought they must all be at one in wishing to feel absolutely secure against a call, if that were possible. He wished to state that before the Board did anything to place the proposal for the reduction of capital before the shareholders the first step they took was to consult the solicitors of the Company as to whether that would in any way prejudice the action against the promoters, and it was only upon receiving an emphatic assurance that it would not in any way prejudice it that the Board decided to make the proposal. The Board had not the slightest wish to impede these legal proceedings, for if any benefit was to be derived therefrom some of the gentlemen on the Board would derive a greater advantage than any one else, and if they could be protected against a call without any reduction of capital they wished for no reduction of capital. They simply wanted to be protected against calls, not to screen the promoters. The question was should they begin proceedings at once and remain liable to calls? or should they agree that those proceedings be deferred for a short time, and be no longer liable to calls? They (the Board) had no sympathy with the promoters, but desired, on the contrary that they should be proceeded against and pressed as much as any one, and if the committee thought their funds were ample to meet the possibilities of the case he did not see why they should object to the course then proposed.

Admiral INGLEFIELD thought the guarantee of the committee should be enough.

Mr. PEEBLES thought no one would doubt the *bonâ fides* of the committee. He was a large shareholder himself, and he had many friends deeply interested in this unfortunate business, and could it be for a moment thought that the committee would make a call after what had been said? As to the reduction of capital they might all have agreed to that if it could be done in five minutes, but the chairman knew as well as the solicitor that it would take from three to five months to reduce the capital by law. [Voices: Six months.]

Mr. BROWN (the solicitor) said he had conferred with Mr. Crisp, and they came to the conclusion that if everything went smoothly it might be effected in three months, if no difficult questions arose. He then explained the technical legal process that had to be undergone before the reduction of capital could be made, and concluded by saying that the claim against the promoters had been gravely prejudiced already by the delay that had taken place in enforcing it, and therefore he said that unless there was a very strong reason indeed for delaying the passing of the resolution for winding up it would be most unwise on the part of the meeting not to pass it.

After some further discussion on the subject of the possibility of a call being made,

Mr. BROWN prepared the following minute, which was appended to the resolution:—"The liquidators being present undertake that they will make no call upon the shareholders unless authorised so to do by a resolution of the general meeting of the Company specially convened for that purpose."

The motion was then put on this understanding, and declared carried.

Mr. BROWN assured the meeting that the expenses connected with the liquidation would be kept as low as possible, and as to any other expense he might say it would not be incurred at all by the committee, unless they saw that the opinion which he ventured to express upon the matter was confirmed by the fullest investigation.

Mr. PEEBLES then proposed the following resolutions, which were duly seconded, put to the meeting, and carried:—

"That, in the opinion of this meeting, it is desirable that the Company should be wound up, and that the same be accordingly wound up voluntarily."

"That Alexander Peebles, Admiral Sir Edward Augustus Inglefield, Lawrence Engel, and Charles Bell be, and they are hereby appointed to be liquidators of the Company, with power to continue to carry on the business of the Company, in so far as they may consider requisite or necessary for utilising and realising to the best advantage the assets of the Company, including the provisional orders."

"That the liquidators of the Company be, and they are hereby authorised to take such proceedings as they may be advised in connection with the promotion and formation of the Company and the purchases of the licenses, with full power to compromise, upon such terms as they may think fit, any such claim, or any other claim which they may in the course of the winding up be advised to make against any company, firm, or person."

"That the said liquidators are hereby authorised to transfer or sell all or any of the assets of the Company to any other company, formed or to be formed, and to receive in compensation, or part compensation, for such transfer or sale, shares or other interests in any such other company, or to receive in compensation, or part compensation, for such transfer or sale, the right to participate in the profits of, or receive any other benefit from any such purchasing company."

Mr. PEEBLES wished to say, with regard to the late manager of the Company (Mr. Pollock), that the committee did not consider the charge of the directors for dismissing that gentleman from office was well founded, and that there was no doubt that Mr. Pollock had to a large extent been instrumental in the independent investigation of the circumstances in connection with the promoters of the Company, which resulted in the unanimous resolution come to on the 12th Feb. last, that action should be taken against the promoters. There was little doubt that Mr. Pollock met with great opposition from the Board in his endeavour to bring this about—hence his dismissal. But so far from Mr. Pollock having been deserving of blame, the committee thought he was entitled to the thanks of the shareholders for the manner in which he sought to protect the interests of the shareholders. He concluded by moving, "That this meeting, after hearing from the shareholders' committee their opinion as to the circumstances connected with the dismissal of Mr. Pollock by the Board, desires to record, that in the opinion of this meeting the dismissal of Mr. Pollock was not justified, but that, on the contrary, the thanks of the shareholders are due and are hereby given to him for the manner in which he upheld the true interests of the Company, and to the shareholders in pressing for a thorough investigation into the acts of the promoters and the commencing of proceedings against them."

A SHAREHOLDER seconded the motion, and endorsed what Mr. Peebles had said.

The CHAIRMAN explained that the circumstances in connection with Mr. Pollock's dismissal took place while he (the speaker) was absent from England, and he and his colleagues would have no objection to the motion.

Mr. TOTTENHAM said he was in England when Mr. Pollock was dismissed, and contended that he was deservedly dismissed.

The motion was then put and carried almost unanimously, and a vote of thanks having been accorded to Mr. Borrer for presiding, the proceedings terminated.

## GULCHER ELECTRIC LIGHT AND POWER COMPANY.

An extraordinary general meeting of the shareholders in this Company was held at the City Terminus Hotel, Cannon-street, on Wednesday last, under the presidency of Mr. Daniel De Castro.

The CHAIRMAN, in opening the proceedings, explained that he assumed the position of president, he might say, virtually on the nomination of Professor Crookes, who, from the pressure of his other avocations, could not afford the time necessary to attend properly to the affairs of the Company.

Digitized by Google

The SECRETARY (Mr. Russell Day) afterwards read the minutes of the last extraordinary meeting and the notice convening the present one.

The CHAIRMAN then said that the shareholders would have all received the circular letter and report sent to them on the 22nd February, which stated concisely all or very nearly all that he had told the shareholders when they were at the last general meeting. This report was summed up under the heads of "investigation committee," of "finance committee," and of "works committee"—the three committees into which the Board resolved themselves almost immediately after their appointments. He did not know that he need occupy the time of the meeting at any length in discussing the facts set forth therein, but he had just summarised them a little, and he thought the substance of the report amounted to this—that their investigation committee had obtained from the promoters of the Company £70,000, part of the £100,000, purchase money, which was paid for the patents, and they had also obtained in consequence of that a further voluntary surrender by Messrs. Crookes, Gulcher, and Groth of £19,050; so that, from the purchase money £89,050 had been taken off. The result of their finance committee's labour was, shortly, this: They had reduced the rent of their premises by £200; induced their consulting electrician to postpone the annual fee to which he was entitled for five years, until such time as there was a payment of a dividend of 5 per cent. to the shareholders; and introduced other economies in the administration of the Company, which could not be dealt with in the circular, but a few of which he would mention to them. The directors' fees, according to the Articles, were £1,500; there was a managing director at £750, a secretary at £200, and a cashier at £150, making £2,600. That amount would now be reduced to £1,200, and after adding to it a rent of £200 a year for their City office there would be a net saving of £1,200 effected—the amount mentioned in the circular. It was called there merely £1,000; but as a matter of fact it worked out to be even more than £1,200. The only increase was in the rent of the office in the City, but it was found simply impossible to carry on the business of the Company and to have Board meetings at Battersea, and to have those Board meetings properly attended there. Notwithstanding the fact, however, that they had gone to the expense of a City office, they had reduced the expenses by the amount he had stated. The office, it was to be hoped, would be not only an expense but a great advantage in many ways. With regard to the further saving of Messrs. Ransome's commission, which was mentioned at 4 per cent., upon a turnover of £50,000 (which was the smallest turnover they could possibly exist upon and hope to pay a dividend), it would be a saving of £2,000 a year, which that firm had given up for a couple of installations that would not cost the Company £500. Now, to pay a dividend of 5 per cent. on their reduced capital would take something under £5,000, whereas to have paid the same dividend under the old circumstances would have involved a sum of about £15,000. The only passage in the circular which he thought it was worth while calling attention to was perhaps that which referred to the installations they had in hand. First of all they referred to Lyttelton Harbour. He was not about to go through the list again which he had given at the last meeting of some thirty or forty installations which they had either completed or were in process of completing during the last six months, because the three or four mentioned were sufficient to show them the character of the business being done. The lighting of Lyttelton Harbour in New Zealand had been obtained by the Company in supercession of the Brush Company, who did not give satisfaction, and against whom this Company competed. The installation was one of fourteen or fifteen 2,300 candle-power lamps, and the machinery to drive it. In London the largest oil mills in Bermondsey were lighted partly with the arc and partly with the incandescent light, and already the installation there had borne fruit in the shape of applications from other mills for tenders from the Company to light their factories in the same way. They hoped that the installation at Birkenhead—a very large and important one—would produce like results; but the most important of the lay installations—if he might call them so—was, perhaps, that of the Crystal Palace. The Company had already in progress there an installation of 75,000 candle-power arc lamps. This would be the largest arc lamp installation in the world, and was based on figures which he thought would not only produce a profit directly, but must, having regard to the fact that there was to be an international exhibition there, save them in advertisement if the thing were properly done. Then with regard to the City of London and the lighting of a section there, which was stated in the circular to be an offer to the Company, he was requested to correct that. It was not exactly an offer to the Company, because no contract was made—it was offered to them at no price, but they were one of two companies who were selected after their system had been examined, and they were allowed to tender for the lighting of a portion of the City. For the reasons given in the circular they had declined to entertain it for the present, but if they became stronger and had funds which they did not know what to do with, they might probably go in for that in the future. A much more important thing they thought was to attempt to do what they could do easily. They could easily light mills where power was provided, and ships also where power was provided, and in both of these directions there was simply endless scope. He had been down at Portsmouth with their manager and electrician, and they were simply astounded at what they saw there. That town was simply a wonder of electrical appliances, and the way in which art had triumphed over nature in Portsmouth Harbour in the direction of electric lighting was simply marvellous. The contrivances for electric lighting were so beautiful that any one with the least interest in electricity at all ought to get an introduction to the dockyard to see how matters were managed there. The chairman then warmly acknowledged the reception which he and the gentlemen who accompanied him met with at the dockyard, and went on to say that he hoped the Company had established a footing there which would be very useful to them. The authorities at the dockyard were extremely pleased with the Company's system, and he thought he might say this was not so in the case of most of the others. The high tension system, and the dangers attaching to high tension machines, had in every sense shocked the Admiralty, who were looking out for low tension dynamos, and of those low tension dynamos he was told theirs were the most satisfactory up to the present time. They had sent an installation to the "Vernon" and another was being tried in order, if it was satisfactory, to be sent to the "Minotaur," which was the Duke of Edinburgh's flagship. They had also before them four or five other tenders which they would succeed in getting—at any rate some of them. But they need not be the least afraid if all of them were not secured, because there was so much to be done that all the electric light companies in London could not do it, and therefore what they could do in electricity was what very few other businesses could do—they could rejoice in the success of one another, in the feeling that all this was pushing electricity forward. He then proceeded to say that the immediate object of the meeting was to pass a resolution altering the regulations of the Company, as stated in the motion which he would submit. If it were confirmed at the next meeting the directors would move a resolution providing for the way in which the surrenders were to take place. The proposal would, he said, involve the modification of the conditions contained in the Articles of Association of the Company, reducing the capital of the Company from £300,000 to £150,000. As to the £70,000 which he had informed them had been given up by the promoters, the figures really amounted to £77,000, but the £7,000, which would leave a net balance of £70,000 surrendered by them, was money which had been paid by them on account of further calls on their shares, and which had been allowed to them in account. As they had paid £7,000 in cash, the directors had issued £7,000, roughly, in fully-paid shares, in place of the £7,000 which they had paid. He then went on to indicate other steps which would be taken to extinguish other shares, and to cancel unissued shares, in order to reduce the capital to £150,000. Many of the shareholders, he said, appeared to be anxious to secure a Stock Exchange quotation, and he understood that at a Board meeting the previous day, in his (the chairman's) absence at Portsmouth, it was decided to recommend the shareholders to consent to the cancelling of a sufficient number of the unissued shares to secure a quotation on the Stock Exchange. The result of all these arrangements was that the dividend-bearing capital of the Company had been reduced by £105,000. It was really reduced by £106,050, but having regard to the fact that the whole capital paid up was over £196,000 under the old arrangement, and that had been reduced by £106,000—so that the capital was only £90,000—he hoped they would regard the result as a satisfactory one for the last three months' labours of the three committees. He concluded by moving the following resolution: "That the regulations of the Company be altered by the addition of the following regulations:—First, the directors may accept surrenders of shares on such terms as they think fit, provided that no part of the assets of the Company representing paid-up capital be employed in the purchase of the Company's own shares. Second, the directors may sell any surrendered shares, and register the purchaser as the holder thereof, and may cancel any share acquired by surrender, and may (unless the Company otherwise resolve), issue new shares in lieu thereof."

Major COTTON seconded the resolution, which was carried with one dissentient—Mr. Hadland—who intimated that he objected to the cancelling of the shares, a subject which, the chairman pointed out, was not before the meeting.

The CHAIRMAN, in reply to a question, said that Mr. Crookes was entitled to 500 guineas a year payable out of capital, and that gentleman had consented to take that amount out of profits instead of out of capital. If they declared a dividend of 3 per cent. (and they would declare a dividend as soon as they could), then Mr. Crookes would be entitled to take from the profits of the Company the same amount which the ordinary directors of the Company took, and that amount would be paid to him on account, and would be debited to his account on account of the 500 guineas fee. At the present moment the ordinary directors were taking only 100 guineas each per annum. If a dividend of 3 per cent. were declared, Mr. Crookes would get 100 guineas, and the 400 guineas would be postponed. That was the arrangement with Mr. Crookes.

A vote of thanks to the chairman and directors was, on the motion of Mr. Biggs, seconded by Mr. Charlewood, next passed, the services of the Board being warmly eulogised.

The CHAIRMAN, in returning thanks, observed that the electric light had only just lately turned the corner and established itself as feasible and practicable. The losses sustained so far had been through the fault of the public, who had thrown so much money into electric lighting before it was ripe. But now he believed it had fairly turned the corner. He intimated that the directors intended to ask for authority to issue at least £12,000 in 6 per cent debentures, in order to avoid the necessity of making a call on the shares, and to carry out contracts which they were convinced would be profitable. He added, as showing their confidence in the success of electric lighting generally, particularly that of the Gulcher Company, that nearly half of this sum would be subscribed by Mr. Crookes and the directors.

Mr. DEFRIEZ proposed, and Mr. DAVIDSON seconded, a vote of thanks to Messrs. Crookes, Gulcher, and Groth, for the liberal manner in which they had met the views of the directors.

The motion having been unanimously accorded,

Major COTTON referred to the loss of part of the capital of the Company, and suggested that at a future meeting they should face the difficulty and write off the amount. He himself held nearly 600 shares, and he suggested that £1 a share out of the £3 10s. paid up should be written off. That would get rid of the incubus, and put them in the way before long of paying a dividend.

The proceedings then terminated.

TO TELEGRAPH OPERATORS.—GOOD MORSE HANDS WANTED for service abroad.—Apply, by letter, to SECRETARY, care of Read and Nephew, 1, Sherborne-lane, London, E.C., stating age, experience, present employment, state of health, &c. Married men need not apply.

TO AGENTS, TRAVELLERS, and CANVASSERS.—The ELECTRIC "SUN" LAMP AND POWER COMPANY, Limited, are PREPARED to APPOINT the ABOVE to introduce their perfect system of Electric Lighting as in use at the South Kensington Museum and elsewhere. Terms liberal. Applications, in writing only, to be made to the SECRETARY, 6, Ridinghouse-street, Regent-street, London, W.

TO ELECTRICAL ENGINEERS, CONTRACTORS, and OTHERS.

TO BE SOLD BY PRIVATE TREATY.

All that the sole and exclusive right to manufacture for the residue of the present patent term, or any extension thereof, the Gramme Dynamo Electrical Machine.

The said right is granted under and by virtue of an indenture, dated the 5th day of April, 1883, and made between the British Electric Light Company (Limited) of the one part, and Emmerson, Murgatroyd, and Company (Limited) of the other part, and is subject to the stipulations in such indenture contained.

And also all the extensive stock of new and second-hand Gramme Dynamo Machines for Arc and Incandescent Lighting, Copper Wire, Arc and Incandescent Lamps, and a large quantity of Cable, Tools, Electrical Apparatus, and loose materials, including Resistance Coils, Galvanometer, &c., used in the manufacture of Gramme machines now in and upon the Heaton Foundry, Stockport, where the extensive business of the said Emmerson, Murgatroyd, and Company has hitherto been carried on.

For further particulars apply to the liquidators of EMMERSON, MURGATROYD, AND COMPANY (Limited), Heaton Foundry, Stockport; or to

Messrs. LAKE and NEW,
Solicitors, Stockport.

RADCLIFFE WARD, Consulting Electrical Engineer, 110, CANNON-STREET, E.C.—For the present Mr. Ward's address will remain as above, where all communications may be addressed to him, marked "Private."

INSULATED ELECTRICAL WIRE, Silk, Cotton, or India Rubber covered. Conductivity guaranteed. German Silver Wires for Resistance. Braided Handle Cord, Silk Cord for Electric Bells, &c.—WILLIAM RICKARD, Derby. London Agent (stock kept), EDWIN HOLLOWAY, 2, Gutter-lane, E.C.

JUST PUBLISHED.—WATCH AND CLOCKMAKERS' DICTIONARY & GUIDE, by F. J. Britten, thoroughly practical, 250 engravings; 5s., postage 5d.—Kent and Co.; and of the author, 35, Northampton-square, E.C.

NOW READY, PRICE 3s.,

THE NEW ENGLISH PATENT LAW,

and the

Patent Laws of all Foreign Countries & British Colonies,

In the form of Analytical Summaries explanatory of the proceedings necessary to obtain and maintain Patents for Inventions at home and abroad.

A. M. & Wm. CLARK, Patent Agents, 53, Chancery Lane, London.

MAGNUS VOLK,

ELECTRICIAN TO THE BRIGHTON CORPORATION,

MANUFACTURER AND CONTRACTOR FOR

ELECTRIC LIGHTING, ELECTRIC RAILWAYS, ELECTRIC APPLIANCES.

DITCHLING RISE TELEGRAPH WORKS,
BRIGHTON.

GRIFFITH & CO.,

4, QUEEN ANNE'S GATE, S.W.

Electrical Engineers and Manufacturers of

RAILWAY TELEGRAPH INSTRUMENTS

And all descriptions of

Fittings for ELECTRIC WORK, HOUSE BELLS, &c.,

And Sole Makers of

Spagnoletti's Patent Railway Locking Apparatus and Fire Alarms.

Works: RAILWAY FOUNDRY, READING.

J. EDMUNDSON and CO.,

ENGINEERS AND ELECTRICIANS,

19, GREAT GEORGE STREET, WESTMINSTER, S.W.

MANUFACTURERS OF

ELECTROLIERS, PENDANTS, AND BRACKETS, AND ALL DESCRIPTIONS OF ELECTRIC LIGHT FITTINGS.

SPECIAL AGENTS FOR HEDGES' PATENT SAFETY FUSES.

THE "SWAN" INCANDESCENT LAMP.

J. EDMUNDSON and CO. having been appointed as SPECIAL AGENTS for the Exhibition and Sale of the SWAN INCANDESCENT LAMPS, are prepared to supply these in any quantities. Also to furnish Estimates for fitting them up complete with all necessary apparatus. The Swan Lamps may always be seen in action at their Show Rooms.

Digitized by Google

## NOTES.

THE JERSEY CABLE.—The cable between Jersey and France is repaired.

KHARTOUM.—Telegraphic communication has been established with Khartoum, in Egypt.

THE ANTIGUA-GUADELOUPE CABLE.—The cables interrupted between Antigua and Guadeloupe have been repaired.

"TIME" IN CEYLON.—Time is transmitted to Colombo by telegraph from the Madras Observatory daily at 4 p.m.

THE MAXIM-WESTON COMPANY.—This company has removed from 47, Cannon-street, to 32, Queen Victoria-street, E.C.

SWAN UNITED ELECTRIC LIGHT COMPANY.—This company have removed from their offices in St. Mildred's-court, E.C., to 57, Holborn-viaduct, E.C.

ELECTRIC LIGHT FOR THEATRES.—The Australasian Electric Light Company have secured a contract for lighting the Princess Theatre at Melbourne.

CHANGE OF ADDRESS.—Mr. C. T. Kingzett informs us that he has removed from 17, Lansdowne-road, Tottenham, to Trevena, Amhurst Park, London, N.

ELECTRIC LIGHTING AT BRISBANE.—The Australasian Electric Light Company are going to light the offices of the *Brisbane Courier* with incandescent lamps.

TELEGRAPH OFFICES IN CANADA.—The total number of telegraph offices in Canada is 2,259, the highest number *pro ratâ* to the population of any country in the world.

THE INDO-EUROPEAN TELEGRAPH COMPANY.—This company has opened a branch office at 10 and 11, Mincing-lane, connected by special wire with the company's chief office at 18, Old Broad-street, E.C.

THE BRITISH MUSEUM.—The Government have declined for the present to provide funds for lighting the British Museum by electric lamps, so that the keeping open of the building after dark has been deferred.

EASTERN EXTENSION TELEGRAPH COMPANY.—The traffic receipts of this company for the month of February, 1884, amounted to £33,102, and to £29,391 for the corresponding period of 1883, being an increase of £3,711.

CANADIAN TELEGRAPHS.—The first link in the Canadian trans-Continental telegraph line has just been completed by the formal opening of the line between Port Moody, on the Pacific Ocean, and New Westminster, in British Columbia.

ELECTRIC LIGHTING FOR CHICAGO.—The Chicago West Park Commissioners have appointed a committee to wait on the manufacturers of various electric lamps to ascertain, and be ready to report, the expense of lighting the parks and boulevards.

TOWER LIGHTING IN AMERICA.—The method of distributing light by means of groups of arc lamps on tall towers, or semaphores, appears to be still in favour with American electricians. The city of Saginaw, Michigan, is about to adopt this mode of lighting.

EARTHQUAKE IN ASIA MINOR.—A Reuter's telegram from Smyrna, dated Feb. 29, says:—"A severe shock of earthquake, lasting two seconds, was felt at four o'clock this morning at Chios, Tehesmo, and Vourla. So far as is known at present no damage has been done.

SIXPENNY TELEGRAMS.—It has now been definitely decided to postpone the introduction of the reduced tariff for inland telegrams until next year. It is generally supposed that the losses sustained by the General Post Office in establishing the Parcels Post have necessitated this delay.

GREAT NORTHERN TELEGRAPH COMPANY.—The traffic receipts of this company for February, 1884, were £19,320. From January to 29th February, 1884, they amounted to £38,680, against £36,458 for the corresponding months of 1883, and £34,360 for the same period of 1882.

DOMESTIC LIGHTING.—Mr. R. H. Harrison, of Ware, writes to say that he has frequently lighted the rooms in his house at Ware with 10 candle-power Swan lamps, on the occasion of dances, &c. He obtains the current from Bunsen batteries, and the result has been in every way satisfactory.

TELEGRAPHIC COMMUNICATION WITH SOUTH AMERICA.—The West Coast of America Telegraph Company notify that telegraphic communication with Valparaiso, the west coast of South America, and Monte Video is now established *viâ* Galveston. The rate to Buenos Ayres is now 9s. per word.

NEW MOTOR FOR ELECTRIC RAILWAYS.—A railway has been built round the Brush Electric Light Works, in Cleveland, Ohio, for the purpose of testing a new electric motor for tramcars. The motor and electrical machinery are placed on the front end. The new motor, if successful, will probably be put in use on the tramcar lines in Cleveland.

THE UNITED TELEPHONE COMPANY'S BILL.—The Camberwell Vestry have agreed to abide by the action of the Metropolitan Board of Works in this matter. They are of opinion that overhead wires generally should be dealt with in a public Bill. We believe that it is the intention of the Government to oppose the Bill of the United Telephone Company when it comes up for second reading.

ELECTRIC LIGHTS FOR LIGHTHOUSES.—The arrangements of the Trinity Corporation are now almost completed for the important series of experiments with electricity, gas, and oil, as illuminants for lighthouses, which will shortly be commenced at the South Foreland Lighthouse. During the past week a Committee of the Trinity Board have inspected and decided on the suitability of the lighting apparatus offered for exhibition.

ANOTHER REDUCTION.—The home of philosophical Radicalism has reduced the price of its gas to 2s. 1d. per 1,000 cubic feet, which it could well afford to do. Out of the profits of last year's gas making the Birmingham Corporation allotted £25,000 to the improvement rate, and £30,000 to the reserve and sinking fund. The supporters of the President of the Board of Trade are adepts in the gas business, and know how to profit thereby.

IRISH TELEGRAPH SERVICE.—In the House of Commons, on Friday, the 29th ult., Mr. Harrington asked why the employment of females in the Postal Telegraph service in Ireland is not more general.—Mr. Fawcett said that the department was anxious to employ women, but there were often difficulties in consequence of the post-office buildings not allowing separate accommodation. With regard to telegraph schools, new entries were taken into the instrument room, and the system was found to work remarkably well.

NEW CABLES.—The *Gazette* prints the following notice, which has been issued by the Austrian Government, relative to new cables laid at Ombla Inlet, in Dalmatia:—"Five telegraph cables have been laid at Ombla Inlet Entrance—from a position 130 yards eastward of Cantafico Point, north side of entrance to Port Gravosa, thence northward to a position 130 yards eastward of Leandra Point. Both these positions are marked by small stone towers, on which is painted in black an anchor (crown up), indicating that anchorage is prohibited on,

Digitized by Google

and at least half a cable on either side of, the line joining the towers."

BICHROMATE CELLS.—A German experimenter has found that with a zinc-carbon battery an exciting liquid composed as follows gives the best result, viz., sulphuric acid, 200 cubic centimetres; bichromate of potash, 25 to 50 grammes; nitric acid (34 per cent.), 100 cubic centimetres; water, 200 centimetres. Dr. Egger, the experimenter in question, has found that with 50 grammes of bichromate the current remains very constant for a considerable period of time, there being no very marked diminution after seventeen hours' working. He also found that the use of the bichromate of potash very materially lessens the nitrous fumes usually given off by this kind of cell.

ELECTRIC LIGHTING IN AMERICA.—Logansport, a town in Indianapolis, U.S., has adopted the electric light to the entire exclusion of other methods of illumination. Judging from the number of lamps employed, viz., fifty, the town would not appear to be a large one. The lamps are hung from arches across the streets, a method of illumination which was proposed in England some time ago, but which did not meet with much favour. The plant has been supplied, and is worked by, the Jenney Electric Light Company, who have entered into a contract with the town authorities for five years. Logansport is evidently a go-ahead little place, whose enterprise is not to be measured by its size.

THE PHONOGRAPH PRACTICALLY UTILISED.—An interesting experiment is to be made by Dr. Zintgraff, who, in company with Dr. Chavanne, is about to visit the Congo and the interior of Africa. "He takes with him," says the *Daily News*, "a phonograph wherewith to fix the speech and melodies of hitherto unknown tribes, which, thus received by the instrument, will be forwarded to scientific men in Germany. The apparatus (which will be used for such a purpose for the first time) has been made by Mr. Fuhrmann, of Berlin, and exactly corresponds with one he has in that city, so that the plates used in Africa can be sent to Berlin to be unrolled by that machine, and caused to re-emit the sounds received."

THE ST. VINCENT-PERNAMBUCO CABLE.—With reference to the interruption on the St. Vincent-Pernambuco section of the Brazilian Submarine Telegraph Company's cable, it is officially notified that, from tests received from St. Vincent, the break is placed from five to ten miles from the shore, in about 300 fathoms. The steamship "Scotia" leaves the Thames on Monday next, and there is every reason to hope that the repair will be shortly completed, and telegraphic communication with South America restored. The Eastern Telegraph Company notifies that during the interruption of the cable telegrams will be accepted, at reduced rates, to go by wire to St. Vincent, thence by first steamer to South America, and onward, by telegraph, to destination.

DR. TODHUNTER.—Isaac Todhunter, whose name is so well known in our schools and colleges, died at Cambridge on Saturday evening last, at the age of 63. Dr. Todhunter took his degree at Cambridge University in 1848, in which year he was senior wrangler. He was also first Smith's Prizeman, Moderator in the Mathematical Tripos of 1865, and Examiner 1866. In 1871 he won the Adams Prize for the best essay on pure mathematics. He was an Honorary Fellow of St. John's College, a Fellow of the Royal Society, and last year was made a Doctor of Science. He was the author of numerous mathematical works, including the "Theory of Equations," "Plane Trigonometry," "Spherical Trigonometry," "Plane Co-ordinate Geometry," "The Differential Calculus and its Applications," "Examples of Analytical Geometry of Three Dimensions," and "Analytical Statics."

ELECTRIC LIGHTING FOR SOCIAL GATHERINGS.—At a dinner given on the 1st of March, by Messrs. Christy and Norris, engineers, of Chelmsford, to their *employés*, and also at a tea for the wives and children on the 3rd inst., the dinner and tea were given in a newly-erected building, which is intended for a workshop. This was brilliantly lighted by means of about 20 Swan lamps, fed by a Crompton-Bürgin machine of the self-regulating type. The machine also supplied current for a Crompton-Crabbe arc lamp, which lighted the approaches to the building, and could be seen for a great distance around. The work was successfully carried out by Mr. F. Christy, jun. This gentleman has also lighted the bacon curing establishment of J. J. Richardson, Esq., of Waterford, by means of a Crompton-Bürgin machine, supplying current for 110 Swan lamps. This installation is giving great satisfaction.

ACCIDENT AT A GASWORKS.—Our friends in the gas world are usually so busy calling attention to any and every little hitch or accident in connection with electric lighting, that they have no time (or inclination, perhaps) to point out the hundred and one little accidents and disasters to which gas is subject. We therefore think it necessary to point out that gasworks, like dynamo machines, are not immaculate, and do now and then collapse, with equal celerity and completeness. Thus, on Wednesday night last, the gasometer at Newport, Isle of Wight, holding 80,000 cubic feet of gas, collapsed "from some unexplained cause," as the daily papers put it. Luckily, the gas does not seem to have exploded. That, we venture to think, was sheer luck; but the inhabitants of Newport, whilst thankful that they have escaped with their lives, will no doubt be of opinion that gas is not always so safe or reliable as its supporters would have people believe.

THE PROTECTION OF CABLES.—In the House of Commons on the 29th ult., Mr. Pender asked the Under-Secretary of State for Foreign Affairs whether the International Conference of Delegates from thirty States, which sat in Paris in 1882 and 1883, on the subject of the protection of submarine telegraph cables, had come to any agreement; and, if so, whether it was likely that any convention would be concluded, and if he would lay the papers connected with the same upon the table of the House?—Lord E. Fitzmaurice replied that the draft of convention drawn up by the delegates at the last conference had since been under the consideration of the Governments represented. An agreement had now been arrived at, and as soon as the requisite authority had been received by the plenipotentiaries of the several powers in Paris the convention would be signed. The signature was expected to take place very shortly, and as soon as possible afterwards the convention would be laid before Parliament.

ELECTRIC LIGHTING FOR OBAN.—This pretty little watering-place on the west coast of Scotland is thinking of adopting the electric light, and considering that it has to pay 8s. 4d. per 1,000 cubic feet for its gas, we think there can hardly be a doubt as to which method of lighting it will ultimately adopt. A few days since the authorities met Mr. Grant, the manager of the Scottish branch of the Edison and Swan United Company, and talked the matter over. It was stated that Oban had 5½ miles of streets, and Mr. Grant was asked what would be the cost of lighting them, if forty lamps per mile were allowed. He replied that the dynamo would cost £200, engine and boiler £100, and the lamps and cable £300 more. The working expenses of the lamps for 1,000 hours' lighting would be £42, fuel £50, and the other expenses might bring it up to £150 annually. He suggested that a committee should be

Digitized by Google

formed to promote the matter, and that the best way to go to work would be to form a small company, with a capital of £5,000 or thereabouts. The meeting agreed to this, and a committee was formed, with Provost Menzies at its head, and Mr. D. C. Brown as secretary. The meeting were of opinion that endeavours should be made to utilise the water-power round Oban.

Overhead Wires in Wandsworth.—The Railway Commissioners had before them, on Friday, the 29th ult., an application for directions as to the mode of procedure in the case of the arbitration between the Postmaster-General and the Wandsworth District Board of Works, held before the stipendiary magistrate, Mr. Paget. Mr. Lane appeared for the Wandsworth District Board, and stated that the Act of 1863 gave an absolute right of veto to prevent the erection of overhead wires; but the Act of 1878 modified that by giving power to the stipendiary magistrate to act as arbitrator, and if the parties were dissatisfied with the award, as in this case the Wandsworth Board were, then the parties could go before the Railway Commissioners. — Mr. Casserley, who appeared for the Post Office, said the Postmaster-General, wishing to erect certain wires at Wandsworth, asked the consent of the District Board, who refused their consent, and then the Postmaster-General gave them a formal notice requiring them within a specified time to give their consent. They did not give their consent, and thereupon the whole matter stood referred to Mr. Paget, the magistrate of the district; and he had made an award which, with one or two exceptions, gave the Postmaster-General consent to erect the particular wires which the Postmaster-General asked the Board to grant. He submitted that that consent operated to all purposes as if it were a consent given by the Wandsworth District Board of Works.—Mr. Commissioner Miller said this was a re-trial of the difference between the parties and not an appeal. The case was in the same position as if it were referred to them in the first instance.—After some discussion it was decided that the parties should come before the commissioners, not on appeal from the arbitrator, but as a court of first instance trying a case *ab initio*.

Press Telegraph Rates in America.—In the course of his evidence before the Senate Committee on Post Offices, &c., who are going into the question of a Government telegraph system for the United States, Dr. Norvin Green, President of the Western Union Telegraph Company, said that in the States operators were paid higher rates, material was more expensive, and all the cost of construction was greater. A new tariff was in process of preparation to go into effect on March 1, giving a maximum rate of 1dol., for which sum a message could be sent 4,500 miles, from Halifax to Washington territory. Dr. Green said he would furnish the committee with a copy of the contract with the Associated Press. It contained, he said, a clause that no cheaper rates should be made with any other association without giving the Associated Press the advantage of the reduction. Some papers had complained because the Western Union could not furnish them news at the same rates their neighbours were receiving it from the Associated Press. It was manifest that the papers could get cheaper work done by association, and that the Western Union Company could not transmit press despatches to a single paper at as low a rate as it could carry the despatches of an association. Despatches from Washington to New Orleans, for example, were dropped at sixteen different points along the line. A contract had recently been made with another press association, the name of which he could not recall. He would send the committee copies of both contracts. A careful estimate of the cost of press work performed by the Western Union showed an average of 6½ cents per 100 words. With reference to the capitalisation of the Western Union Company, he said it made no difference with the rates. If no profit was made, it was all the same whether the capital was small or great. There had been capitalisation of stock since 1866, without a representation in values.

Timely Generosity.—We have great pleasure in recording an act of generosity, which was as kindly as it was timely. Suspense is by general consent allowed to be hard to bear, and what suspense can be worse than that which follows the news of a great victory? Who have died? and who are wounded? are questions the solutions of which are anxiously awaited by parents and relations at home, when the telegraph flashes the news that the British arms have proved victorious. Those, therefore, who were most concerned in the safety of friends and relations in the recent action at the Wells of Teb, will know best how to appreciate the generous action of the Eastern Telegraph Company in allowing wounded officers and men to telegraph home to their friends free of cost, and thus forestal or amplify, as the case might be, the necessarily brief and often misleading "Official List of Killed and Wounded." That the officers and men themselves were grateful for this kindness on the part of the Eastern Telegraph Company is sufficiently shown by the following message from General Stephenson, commanding the army of occupation in Egypt, received by the Managing Director of the Company. He says: —"I have the honour to acknowledge your letter of yesterday's date enclosing the complimentary and considerate telegram sent by direction of the chairman and directors of the Eastern Telegraph Company. May I request you to convey to those gentlemen my best thanks for their generous and patriotic action in allowing wounded officers and men of Her Majesty's service to communicate by telegram with their friends, free of expense, a boon which will, I feel sure, be most thankfully appreciated by the wounded of both services?—(Signed) T Stephenson." It only remains to add that the company are merely following out the large-hearted policy first displayed by them during the Natal war, when the same privilege was granted to the wounded officers and men, and largely taken advantage of. We heartily congratulate the Eastern Telegraph Company on their generosity, and think they deserve the thanks of the nation at large.

Electric Lighting in Ironworks.—Messrs. Thwaites Brothers, of the Vulcan Ironworks, Bradford, Yorks., have adopted the electric light as a means of illuminating a portion of their extensive works. At present the light has only been fitted in the erecting shop, a large building some 40ft. high, of about the same width, and, perhaps, 60ft. in length, without any floors. The difficulty of lighting a large building such as this, in which the centre must be kept clear of all fixtures, so as to allow of the manipulation of large castings by an overhead travelling crane, is one which presents features of peculiar difficulty. With gas it was practically impossible to light the place at all adequately, and after dusk it was not considered safe to go on with work which involved the constant moving of heavy castings, so that during the winter months, and especially on dull and foggy days, work was frequently brought almost to a standstill. These difficulties led Messrs. Thwaites Bros. to consult Mr. Wilson Hartnell, engineer, of Leeds, who advised the introduction of Crompton arc lamps. The installation consists of a Crompton-Bürgin dynamo, and six of the Crompton-Crabbe arc lamps. Each lamp carries two pairs of carbons, so that when one pair is burned another is automatically switched into circuit. It is found by Messrs. Thwaites that the light thus given is per-

Digitized by Google

fect for their purpose. Although from the necessity existing for placing the lamps around the sides of the room much light is wasted, yet still the whole area is so well lighted that work can be carried on at night as well as in the daytime. The dynamo is driven by a belt from the main shafting, with a counter-shaft intervening, and is thus liable to considerable and frequent variations in speed. This, of course, affects to some extent the steadiness of the light. The consumption of power is comparatively slight, and, in the case of Messrs. Thwaites Brothers' installation, is not an appreciable consideration. The lamps and dynamo require very little attention, and are kept in order by one of the workmen in the employ of the firm. After having been at work for several months, the installation has on all hands been pronounced to be very successful in every way.

THE TELEPHONE IN GLASGOW.—In Glasgow the National Telephone Company have adopted, so far as possible, the policy of opening subsidiary exchanges, wherever a sufficient number of subscribers could be obtained, in order, not only to give all firms the benefit of the system at the ordinary rate, although they were outside the usual radius from the centre of the city, but also to keep down as much as possible the mass of wires in the centre of the town. So long as there were only three or four of these exchanges no difficulty was found in connecting these together by trunk wires, but when they increased in number (there are now seven in Glasgow), and as also the number of subscribers increased, it became a matter for consideration, how satisfactory and quick trunk service was to be given between these exchanges. The system which has now been adopted and put into operation is, we believe, already in use in some form in Paris, but not in any town in this country, and a short account of it may be interesting. An exchange has been opened quite distinct from any of the other exchanges, and which is called the Trunk Exchange. It is connected with all the other exchanges by numbers of wires varying according to the numbers of the subscribers in each exchange, the total number of trunk wires now in use in Glasgow being ninety. In the Trunk Exchange is an ordinary cord switch-board, but with no indicators, and specially designed for quick service. From each exchange is a speaking wire to the Trunk Exchange, which is in connection with a key on the operator's table. The mode of getting connected is as follows:—The operator wishing another exchange presses the key, which cuts his instrument into the speaking wire, and so puts the operator instantaneously in connection with the Trunk Exchange. She then gives the name of her own exchange and the name of the exchange wanted. The trunk operator at once and by one movement connects the wires, which makes a direct wire between the exchanges wanting each other. As the trunk operator has simply the wires to connect and nothing else to do the connection is made very quickly. It has been carefully timed, and it is found that communication is established in four seconds. It is found that the one operator can handle the ninety trunk wires with ease. If the speaking wire was to go out of order it will readily be seen that the system would be seriously disorganised, but provision has been made against this by arranging that in the case of such a thing happening one of the other trunk wires can be at once substituted, and by the operators themselves. The system is found to work admirably, and has tended to improve the service, there being now no delay in getting through from one exchange to another. The work has been in progress for the last three months, but the final change was made between last Saturday night and Sunday morning. The whole work of designing and fitting up the apparatus and making the necessary alterations, and also in adapting the system to the special requirements of the work has been carried out under the direction of Mr. D. Sinclair, the engineer and electrician of the company's Glasgow district.

ATMOSPHERIC ELECTRICITY.—M. de Tromelin accounts for the production of what is known as atmospheric electricity as follows:—"The wind in grazing the surface of the sea carries with it the aqueous particles of the crest of the waves, which here play the part of the comb in Armstrong's machine. The roughnesses on the surface of the soil play the same part when a moist wind blows over them. These particles of water retain their electricity, and rising in the atmosphere form clouds, and as electricity passes to the surface of bodies, they tend to spread over the highest atmospheric surfaces; and I hold, with M. Faye, that the cirrus must retain great part of this electricity. That being admitted, it may be conceived that a cloud is electrified if formed in the conditions just cited. It would not be the case with a cloud formed by mere vapours rising in the air in the morning. But to produce lightning there must be a discharge between the cloud and another point, the earth or cloud, such that the difference of potential between the point and the cloud, at the moment in question, is sufficient to produce the lightning. But the distance across which the spark passes depends on the *electric pressure* and on the mechanical resistance which the medium presents to the discharge. This pressure varies with the square of the potential of the cloud, its form, its surface, the charge of the cloud, and its distance from the point in question. But the potential energy of a cloud depends on its form, its surface, and its temperature. When this cloud originally electrified undergoes any change whatever (condensation, congelation of aqueous vesicles, &c.), it absorbs a certain amount of energy, which should be found in the form of an increase of potential energy. This consequence results from the principle of the conservation of energy, and from Carnot's principle, from which Lippmann has deduced such remarkable results. If, then, we suppose that the charge of the cloud remains constant for a certain time, condensation or lowering of temperature will increase the potential of the mass. During a storm, it is very exceptional when there are no electrical manifestations. The abundant condensation then observed is the cause of an increase of potential of the storm-cloud, and when this potential is sufficient, discharge takes place in the form of lightning. Moreover, the continued renewal of the charge indicates that the cause must reside in the storms themselves. Air being a dielectric, the vapour becomes the natural reservoir of the electricity. Imagine a mass of electrified aqueous vapour in suspension in the air. At night, when the sun has disappeared, there will be a cooling of the cloud-mass. For the reason above given its potential will increase. Now, if the potential reaches a certain extent, the vesicles considered separately can no longer retain their charge—that is to say, they will escape into the air in the form of silent discharges. It is calculated that, at the ordinary pressure, a small sphere, 0·6 millim. in diameter, cannot retain electricity at the potential obtained with our ordinary machines. From the small radius of the vesicles it will be seen that a cloud cannot retain a charge at a potential exceeding a certain amount. In this way would be produced the phenomenon known as heat lightning. As these lightning flashes are seen by different observers in the horizon, it is logical to suppose that they are also produced at the zenith, and that they are not the reflections of the lightning due to storms at a distance. A similar phenomenon occurs with a traveller who always sees a layer of fog towards the horizon, while the sky above is clear. This is

Digitized by Google

only due to a different thickness of the layers traversed by the visual rays." M. de Tromelin put forward the above theory at a recent meeting of the Paris Academy of Sciences.

THE PROGRESS OF ELECTRIC LIGHTING.—On Wednesday evening, at the Society of Arts, Mr. W. H. Preece, F.R.S., read a paper on this subject. The room was crowded with an attentive and appreciative audience. Sir F. Abel presided. The text of the paper was a sentence from the report of a company's meeting, that "electric lighting was at present a failure, and the sooner the public were made aware of it the better for their pockets." The object of the paper was, in a great measure, to prove the exact contrary. "There is no doubt," said Mr. Preece, "that the disgraceful financial swindlings, and remarkable gullibility of the investing public, of the past two years, have materially checked the progress of electric lighting by destroying confidence in its success, and thereby withholding the sinews of war by which alone ultimate success can be secured. With millions thrown in the gutter, it is not to be wondered at that investors button up their pockets when the words electric light are mentioned; but, leaving aside the question of the gross mismanagement which has allowed immense sums to be squandered, I propose briefly to indicate some of the progress made, both in a scientific and practical sense, and to show that electric lighting is a real true success." Reference was made to the fact that absolutely nothing had been done to carry out the provisional orders and licenses obtained. The author was most emphatic in his denunciation of the Electric Lighting Bill. It effectually checked a monopoly by strangling the work. He maintained that the electric light was a success, that it would be utilised, no matter the cost, because it was purer, softer, and better in every respect, than any rival. The improvements in dynamos introduced by Crompton, Edison, Hopkinson, and others were mentioned, as well as the saving effected in the cost of leads by the device introduced about the same time by Hopkinson on this side and Edison on the other side of the Atlantic. The question of overhead wires was handled with some amount of caution, objected to as at present employed, but allowed under conditions as suggested to methodise the erection and maintenance, and minimise the danger. "The cure is proper subways." The value of arc lamps for lighting large spaces was dwelt upon, as were the improvements recently introduced by various makers to ensure steadiness and certainty of action. The following remarks about incandescent lamps are worth careful consideration:—"For general domestic illumination the glow lamp, as made by Swan and Edison, is, in my opinion, the only proper one. At the Munich and Vienna Exhibitions, a remarkable lamp by Cruto, of Turin, was shown. It was said to be a carbon tube of high resistance. It gave very good results, and absorbed a very small current, but it is not in the market yet. At Vienna, the Bernstein lamp attracted much attention. It also was a thin carbon tube made by carbonising a hollow silk ribbon, but it had low resistance, and required much current. It gave a considerably higher candle-power than we are accustomed to. For instance, one lamp requiring five amperes and 30 volts, gave 60 candles; and another, with 8·5 amperes and 35 volts, gave 100 candles. Its normal efficiency of 2·5 watts per candle was very low, the efficiency of the Swan lamp being 3·5 watts per candle, and that of the Edison 4 watts per candle. Its duration is said to be very great. All glow lamps can be made to give economical results when we use large currents, but unfortunately their life is much curtailed by doing so. The filament is disintegrated, and the inside of the glass is, in consequence, covered with a dark deposit. Hence we are obliged to be satisfied with low efficiency to obtain reasonable durability. The Bernstein lamp is, however, of an inconvenient power, and while it may do for street lighting, and for large spaces, it is not adapted, in its present form, for our rooms and offices. It is, therefore, a lamp that is more likely to replace arc lamps than the present glow lamps, as made by Edison and Swan. It has, however, shown us a direction in which economy can be effected, and we may reasonably hope that the workers in this field will soon find a means to improve the present efficiency of the small glow lamps, and thus reduce the cost of working them. A good many private houses, as well as public establishments, have been recently fitted up, and their experience has developed many difficulties and dangers which have only to be found out to enable them to be overcome. There is no use ignoring the fact that the admission of electric currents into our homes means the admission of a new danger—a danger that is only to be surmounted by the dictates of experience. Careful rules and regulations have been drawn up for the guidance of those who are executing installations, but the true remedy is to employ none but skilful and experienced contractors, and to have premises properly inspected by recognised professional men. Under such guidance electric light leads can be made absolutely harmless and devoid of all danger. The same cannot be said of gas, oil, or candle, for they involve the use of matches, and are always in a condition of potential danger. 2,041 persons in England alone, in 1881, met with violent deaths from burns, scalds, and explosions (not in mines). In one week, not long ago, six deaths from gas were recorded in *The Times*. Hence, while electricity is certainly accompanied by its own dangers, these dangers can be neutralised, and other infinitely more serious ones can be completely expelled from our houses." The work of Mr. Hedges and others, in connection with cut-outs, measuring instruments, &c., was mentioned; and Mr. Preece then dealt with the great want of a good, trustworthy secondary battery, which he considered the true solution of "isolated house lighting." The many successful applications of the electric light, and the gradual extensions, were brought forward as a proof of the incorrectness of the statement quoted at the commencement of the paper. The complete paper will be found in the *Society of Arts Journal* of to-day. We regret that we cannot report it fully, and must be content with one further quotation. At the conclusion of his paper, which took nearly an hour and a half to read, after referring to light, &c., by gas, the able author concluded with these remarks:—"But why draw a comparison? People do not compare the cost of gas with that of candles, nor the price of a pheasant with that of a mutton chop. If we want a luxury we must pay for it, and if the price of the luxury is not too great, people will have it. People will have electric light, if it can be supplied to them, not because it is cheap, but because it is safe, healthy, pure, soft, and natural. And, moreover, they will not object to pay any reasonable price for it, whatever may be the price of gas. Gas is most destructive, unhealthy, and objectionable when used for artificial illumination. The proper function of gas is the production of heat, and we see in this room how this production of heat can be utilised to form electric currents which diffused about us a real luxury—pure light. When the electric light can be supplied, questions of sanitation, ventilation, and decoration will determine its use, and not questions of price. At present it is a luxury for which we must pay; but the progress made is so rapid, and the room for improvement so great, that the day is not far distant when we shall cease to regard it as a luxury, but we shall demand it as a necessity."

## ELECTRO-CHEMISTRY.

### INORGANIC.

BY DR. G. GORE, F.R.S.

(CONTINUED FROM PAGE 367.)

**Formation of Tetrafluoride of Platinum.**—In some experiments of mine a platinum anode in water, containing 10 per cent. of pure anhydrous hydrofluoric acid, was not corroded by the passage of a current from six Smee or six Grove elements during many hours. Very free conduction occurred, a powerful odour of ozone and a gas which inflamed a red hot splint were evolved at the anode, but no platinum was deposited. With an aqueous solution of pure potassic fluoride precisely similar effects occurred.

A current from 24 elements of magnesium and platinum in an exciting solution of common salt, was passed during 18 hours, by means of platinum electrodes, through water containing 40 per cent. of the same pure acid, but no corrosion of the anode took place. With a current from 10 Smee cells and platinum electrodes, I also electrolysed water containing 80 per cent. of the pure acid. Abundant conduction with evolution of hydrogen and ozone occurred; the anode lost 16·58 grains by corrosion during 36 hours, and became covered with a brownish black crust, which partly dissolved in the liquid to a brownish solution. No platinum was deposited, probably because the hydrogen decomposed the solution. I also electrolysed with platinum electrodes the pure anhydrous acid in a precisely similar way to that described under "Fluoride of Palladium." With a current from 40 Smee cells, the anode corroded rapidly, and acquired a dark red brown crust, which was insoluble in the acid, but rapidly deliquesced in the air; it dissolved, with partial decomposition, to a basic salt and formation of a blood red liquid, in water.

By electrolysis with platinum electrodes, during 16 hours, of water containing 40 per cent. of the pure acid, mixed with its own bulk of strong nitric acid, gases were freely evolved; but scarcely any platinum was dissolved, and none was deposited. With an equal bulk of strong hydrochloric acid substituted for the nitric, hydrogen and chlorine were set free, but in four hours' action the anode was very little corroded. With the same volume of sulphuric instead of the nitric acid, after many hours' action, the anode was again but little corroded. With phosphoric anhydride dissolved in the dilute hydrofluoric acid, and the mixture electrolysed, the results were similar. And with much selenious acid dissolved in it, selenium containing traces of platinum was freely deposited, and gas was evolved as before. (See *Phil. Trans. Roy. Soc.*, 1869, p. 200.)

By electrolysing fused fluoride of potassium or lithium with platinum electrodes, the anode was rapidly dissolved, and the resulting salt of platinum instantly decomposed, and its metal set free; and by electrolysing pure double fluoride of hydrogen and potassium in a fused condition, the platinum anode was rapidly dissolved, and a colour imparted to the salt. Fused silico-fluoride of potassium, or the fused fluorides of silver, copper, lead, manganese, or uranium, when electrolysed by a current from six Smee's cells, did not corrode a platinum anode.

**Electrolysis of Tetrachloride of Platinum.**—Pt. $Cl_4$. Molecular weight = 339. This salt may be formed by the electrolysis of hydrochloric acid with a platinum anode and a dense current. According to Commaille (*Chem. News*, Vol. XIV., p. 188) magnesium deposits pure platinum from a solution of platinic chloride. I have observed that crystals of silicon did not acquire a coating of platinum in that liquid. A smooth deposit of platinum upon bright copper may be obtained by immersing the copper in a boiling solution composed of 100 parts of distilled water, 12 of caustic soda (or 40 of sodic carbonate), and 10 of platinic chloride. Copper and brass may also be coated by means of contact with zinc in a solution prepared as follows:—To a solution of platinic chloride add sodic carbonate in fine powder until effervescence ceases, then add some glucose, and afterwards as much sodic chloride as will produce a white precipitate. The solution should be used at a temperature of 60° C. (*Les Mondes, Chem. News*, Vol. XIX., p. 226).

**Separation of Gold.**—Au. Atomic weight = 196·6. A triad cation. Like platinum, gold is very easily separated from its solutions by each of the methods of electrolysis. Thallium deposits gold from its solutions (W. C. Reid, *Chem. News*, Vol. XII., p. 242). Auric terchloride, and the auro-cyanide of potassium are the only common soluble salts of the metal; a solution of the oxide in hydrobromic acid, or of the aurate of ammonia (a very explosive substance) in potassic cyanide previously dissolved in water, may also be employed. A gold anode is corroded and dissolved in various liquids, *e. g.* hydrochloric acid, solution of sodic chloride, &c. Runspaden has observed that a gold anode in dilute sulphuric acid is considerably oxidised, and a definite hydrated oxide of gold is formed (*Chem. News*, Vol. XX,, p. 179). By immersing zinc in a solution of sulphide of gold dissolved in one of sulphide of ammonium, excluded from the atmosphere, it becomes coated with gold (C. D. Braun, *Chem. News*, Vol. XXIX., p. 230).

J. Schiel has produced Nobili's rings on a horizontal plate of burnished gold used as the anode in very dilute nitric acid, the negative pole being a platinum wire, supported a short distance above the gold plate. After passing a current of suitable strength during about ten minutes, the plate was washed, dried, and exposed a few hours to sunlight, the rings then appeared of brilliant colours. With an alkaline solution the effects were less powerful (*Pogg. Ann.* CLIX., p. 493).

Under the influence of an electric current nitric acid dissolves gold (Berthelot, *Jour. Chem. Soc.*, Vol. XXXVIII., 1880, p. 158).

**Formation of Fluoride of Gold.**—By electrolysing pure dilute hydrofluoric acid with a gold anode, in a platinum crucible as the cathode, by means of a current from six Smee's cells, during many hours, the current passed very freely, much gas came from each electrode, and an odour of ozone from the anode. The anode gradually became covered with an insoluble red-brown film. None of the metal dissolved. Similar effects occurred with more concentrated acid, and with a very much stronger current. The red-brown film appeared to be gold; it was insoluble in nitric acid, and when burnished with agate it appeared like gold.

With a gold anode in pure anhydrous hydrofluoric acid, at 10° F., even a current from 40 Smee cells was but feebly transmitted. In one-and-a-half hour the anode acquired a dark, reddish-brown film, with a few crystals, at first of a greenish colour, upon its edges. By exposure to the air the crystals became first yellow, and then red. A current from six Smee's cells was conducted freely by a gold anode, in a solution of pure fluoride of ammonium containing free ammonia. The anode evolved much gas, and became covered with an insoluble, bright, lemon-coloured powder, but no gold appeared on the cathode. By means of a current from three and also from six Grove's elements I electrolysed with a gold anode the pure fluorides of potassium and lithium in a melted state. Metallic gold separated, and the anode was very rapidly corroded.

**Electrolysis of Auric Terchloride.**—Au. $Cl_3$. Molecular weight = 303·1. Sodium amalgam easily reduces a solution of auric terchloride, and, according to G. A. Koenig, even charcoal reduces it to metal by simple immersion (*Journal* of the Franklin Institute, May, 1882; see also *Chem. News*, Vol. XLIV., p. 215). The mere contact of magnesium, phosphorus, arsenic, antimony, tellurium, bismuth, palladium, silver, mercury, copper, and nearly all the base and brittle metals, with this solution separates the metal. I have noticed that crystals of silicon did not reduce it, but that by contact of amylene, "petroleum ether," benzine, coal gas, and numerous liquid hydrocarbons, with the aqueous solution, films of the metal gradually separated (see *Proc. Birm. Phil. Soc.*, Vol. IV., Part I.)

According to D. Tommasi, solution of auric chloride is not reduced to metal by hydrogen or platinum alone, but only by hydrogen in the presence of platinum (*Chem. News*, Vol. XLI., p. 116.)

Digitized by Google

**Electrolysis of Auro-Cyanide of Potassium.**—KCy. Au Cy. Molecular weight = 287·7. In a solution of the double cyanide of gold and potassium, zinc, copper, brass, and German silver became gilded by simple immersion; but platinum, gold, silver, nickel, iron, lead, tin, bismuth, and antimony did not.

This salt, when dissolved in a suitable proportion of water, and a certain proportion of potassic cyanide added, constitutes the ordinary electro-gilding solution. The compound may either be formed by dissolving the salts in water, or by taking a solution of potassic cyanide, and electrolysing it with an anode of gold and a cathode of platinum, until gold is freely deposited. This process, however, leaves a large excess of simple potassic cyanide in the liquid, and also by abstracting some of the cyanogen to form auric cyanide, and substituting oxygen in its stead, it introduces caustic potash, and the caustic alkali gradually becomes carbonate by absorbing carbonic acid from the atmosphere. The solution, when formed, yields by electrolysis gold at the cathode, whilst cyanide of gold is formed at the anode and dissolves.

For deposition of gold by an electric current in solution of potassic ferrocyanide and auric chloride, *see* E. Ebermayer, *Jour. Chem. Soc.*, Vol. XXXIV., 1878, p. 178. For a solution suitable for gilding iron, *see* Watts's "Dictionary of Chemistry," Vol. VIII., Part II., p. 1,119. A great variety of mixtures, containing auric chloride or cyanide, and other substances, such as the carbonates and chlorides of potassium and sodium, sodic bisulphite, phosphate, and pyrophosphate, potassic ferrocyanide, and sulphocyanide, aqueous ammonia, carbonate of ammonium, &c., have been employed for electro-gilding. The particulars of their composition may be found in "The Art of Electro-metallurgy," Longmans and Co.'s "Text Books of Science."

By electrolysing a solution of methylamine with a gold anode and a feeble current during several days I obtained no deposit of gold.

(TO BE CONTINUED.)

## THE THEORY OF MAGNETISM.*

BY PROF. D. E. HUGHES, F.R.S.

The theory of magnetism which I propose demonstrating this evening may be termed the mechanical theory of magnetism, and like the now well established mechanical theory of heat, replaces the assumed magnetic fluids and elementary electric currents by a simple symmetrical mechanical motion of the molecules of matter and ether.

That magnetism is of a molecular nature has long been accepted, for it is evident that, no matter how much we divide a magnet, we still have its two poles in each separate portion; consequently, we can easily imagine this division carried so far that we should at last arrive at the molecule itself possessing its two distinctive poles; consequently, all theories of magnetism attempt some explanation of the cause of this molecular polarity and the reason for apparent neutrality in a mass of iron.

Coulomb and Poisson assume that each molecule is a sphere containing two distinct magnetic fluids, which in the state of neutrality are mixed together, but when polarised are separated from each other at opposite sides; and, in order to explain why these fluids are kept apart, as in a permanent magnet, they had to assume, again, that each molecule contained a peculiar coercive force, whose functions were to prevent any change or mixing of these fluids when separated.

There is not one experimental evidence to prove the truth of this assumption; and as regards coercive force, we have direct experimental proof opposing this view, as we know that molecular rigidity or hardness, as in tempered steel, and molecular freedom or softness, as in soft iron, fulfil all the conditions of this assumed coercive force.

Ampére's theory, based upon the analogy of electric currents, supposes elementary currents flowing around each molecule, and that in the neutral state these molecules are arranged haphazard in all directions, but that magnetisation consists in arranging them symmetrically.

The objections to Ampére's theory are numerous. 1st. We have no knowledge or experimental proof of any elementary electric currents continually flowing without any expenditure of energy. 2nd. If we admit the assumption of electric currents around each molecule, the molecule itself would then be electro-magnetic, and the question still remains, What is polarity? Have the supposed electric currents separated the two assumed magnetic fluids contained in the molecule, as in Poisson's theory? or are the electric currents themselves magnetic, independent of the iron molecule?

In order to produce the supposed heterogeneous arrangement of neutrality, Ampère's currents would have either to change their position upon the molecule, and have no fixed axis of rotation, or else the molecule, with its currents and polarities, would rotate, and thus be acting in accordance with the theory of De la Rive. 3rd. This theory does not explain why (as in the case of soft iron) polarity should disappear whenever the exciting cause is removed, as in the case of transient magnetisation. It would thus require a coercive force in iron to cause exactly one-half of the molecules to instantly reverse their direction, in order to pass from apparent external polarity to that of neutrality.

The influence of mechanical vibrations and stress upon iron in facilitating or discharging its magnetism, as proved by Matteucci, 1847, in addition to the discovery by Page, 1837, of a molecular movement taking place in iron during its magnetisation, producing audible sounds, and the discovery by Dr. Joule, 1842, of the elongation of iron when magnetised, followed by the discoveries of Guillemin that an iron bar bent by a weight at its extremity would become straight when magnetised, also that magnetism would tend to take off twists or mechanical strains of all kinds, together with the researches of Matteucci, Marianni, De la Rive, Sir W. Grove, Faraday, Weber, Wiedermann, Du Moncel, and a host of experimenters, including numerous published researches by myself, all tend to show that a mechanical action takes place whenever a bar of iron is magnetised, and that the combined researches demonstrate that the movement is that of molecular rotation.

De la Rive was the first to perceive this, and his theory (like those of Weber, Wiedermann, Maxwell, and others) is based upon rotation. Their theories, however, were made upon insufficient data, and have proved to be wrong as to the assumed state of neutrality, and right only where the experimental data clearly demonstrated rotation.

I believe that a true theory of magnetism should admit of complete demonstration, that it should present no anomalies, and that all the known effects should at once be explained by it.

From numerous researches I have gradually formed a theory of magnetism entirely based upon experimental results, and these have led me to the following conclusions:—

1. That each molecule of a piece of iron, as well as the atoms of all matter, solid, liquid, gaseous, and the ether itself, is a separate and independent magnet, having its two poles and distribution of magnetic polarity exactly the same as its total evident magnetism when noticed upon a steel bar-magnet.

2. That each molecule, or its polarity, can be rotated in either direction upon its axis by torsion, stress, or by physical forces such as magnetism and electricity.

3. That the inherent polarity or magnetism of each molecule is a constant quantity like gravity; that it can neither be augmented nor destroyed.

4. That when we have external neutrality, or no apparent magnetism, the molecules or their polarities arrange themselves so as to satisfy their mutual attraction by the shortest path; and thus form a complete closed circuit of attraction.

5. That when magnetism becomes evident, the molecules or their polarities have all rotated symmetrically, producing a north pole if rotated in a given direction, or a south pole if rotated in the opposite direction. Also, that in evident magnetism, we have still a symmetrical arrangement, but one

*Paper read before the Royal Institution, 29th February, 1884.

Digitized by Google

whose circles of attraction are not completed except through an external armature joining both poles.

6. That we have permanent magnetism when the molecular rigidity, as in tempered steel, retains them in a given direction, and transient magnetism whenever the molecules rotate in comparative freedom, as in soft iron.

*Experimental Evidences.*

In the above theory the coercive force of Poisson is replaced by molecular rigidity and freedom; and as the effects of mechanical vibrations, torsion, and stress upon the apparent destruction and facilitation of magnetism is well known, I will, before demonstrating the more serious parts of the theory, make a few experiments to prove that molecular rigidity fulfils all the requirements of an assumed coercive force.

I will now show you that if I magnetise a soft iron rod, the slightest mechanical vibration reduces it to zero, whilst in tempered steel or hard iron the molecules are comparatively rigid, and are but slightly affected. The numerous experimental evidences which I shall show prove that, whilst the molecules are not completely rigid in steel, they are comparatively rigid when compared with the extraordinary molecular freedom shown in soft iron. (Experiments shown.)

If I now take a bottle of iron filings, I am enabled to show how completely rigid they appear if not shaken, but the slightest motion allows these filings to rotate and short circuit themselves, thus producing apparent neutrality. Now I will restore the lost magnetism by letting the filings slowly fall on each other under the influence of the earth's magnetic force; and here we have an evident proof of rotation producing the result, as we can ourselves perceive the arrangement of the filings. (Experiment shown.)

If I take this extremely soft bar of iron, you notice that the slightest mechanical tremor allows molecular rotation and consequent loss or change of polarity, but if I put a slight strain on this bar, so as to fasten each molecule, they cannot turn with the same freedom as before, and they now retain their symmetrical polarity like tempered steel, even when violently hammered. (Experiment shown.)

We can only arrive at one conclusion from this experiment, viz., that the retention of apparent magnetism is simply due to a frictional resistance to rotation, and whenever this frictional resistance is reduced, as when we take off a mechanical strain, or by making the bar red hot, the molecules then rotate with an almost inconceivable freedom from frictional resistance.

*Conduction.*

You notice, if I place this small magnet at several inches distance from the needle, it turns in accordance with the pole presented. How is the influence transmitted from the magnet to the needle? It is through the atmosphere and the ether which is the intervening medium. I have made a long series of researches on this subject, involving new experimental methods, the results of which are not yet published. One result, however, I may mention. We know that iron cannot be magnetised beyond a certain maximum, which we call its saturation point. It has a well-defined curve of rise to saturation, agreeing completely with a curve of force produced by the rotation of a bar magnet, the force of which was observed from a fixed point. I have completely demonstrated, by means of my magnetic balance (shown in the library), that our atmosphere, as well as Crookes's vacuum, has its saturating point, exactly similar in every respect to that of iron. It has the same form through every degree. We cannot reduce nor augment the saturating point of ether; it is invariable, and equals the finest iron. We may, however, easily reduce that of iron by introducing frictional resistance to the free motion of its molecules. From consideration of the ether having its saturating point, I am forced to the conclusion that it could only be explained by a similar rotation of its atoms as demonstrable in iron.

Reflection would teach us that there cannot be two laws of magnetism, such as one of vibrations in the ether, and rotations in iron. We cannot have two correct theories of heat, light, or magnetism, the mode of motion in the case of magnetism being rotation, and not vibration.

Let us observe this saturation point of ether compared with iron. I pass a strong current of electricity in this coil. The coil is quite hot, so we are very near its saturation. I now place this coil at a certain distance from the needle (8in.). We have now a deflection of 45° on the needle. I now introduce this iron core exactly fitting the interior, previously filled by the ether and atmosphere, its force is much greater. So I gradually remove this coil to a distance, where I find the same deflection as before (45°). This happens to be at twice the distance, or 16in., so we know, according to the law of inverse squares, that the iron has four times the magnetic power of the ether; but this is only true for this piece of iron. With extremely fine specimens of iron I have been enabled to increase the force of the coil forty times, whilst with manganese steel containing 10 per cent. of manganese, it was only 30 per cent. superior. We see here that the atmosphere is extremely magnetic. Let us replace the solid bar by iron filings. We now only have twice the force of ether. Replace this by a bottle of sulphite of iron in a liquid state. It is now a mere fraction superior to the atmosphere, and if we were still further to separate the iron molecules, as in a gaseous state, it is reasonable to suppose that if we could isolate the iron gas from that of ether, that iron gas would be strongly diamagnetic, or have far less magnetic capacity than ether, owing to the great separation of its molecules. These are assumptions, but they are based upon experimental evidence which give them value.

Let us quit the domain of assumption to enter that of demonstration. Here I have a long bar of neutral iron. If I place this small magnet at one end, we notice that its pole has moved forward 3in., having a consequent point at that place. Let us now vibrate this rod, and you notice the slow but gradual creeping of the conduction until at the end of two seconds it has reached 14in. The molecules have been freed from frictional resistance by the mechanical vibrations, and the molecules have at once rotated all along the bar. (Experiment shown.)

Let us repeat this experiment by heating the rod to red heat. You notice the gradual creeping or increased conduction as the heat allows greater molecular freedom. (Experiment shown.)

Let us now again repeat this experiment by sending a current of electricity through the bar. You notice the instant that I touch the bar with this wire conveying the current through it, that we have identically the same creeping forwards, no matter what direction of the current. (Experiment shown.)

If you simply looked at the effects produced you could not tell which method I had employed, either mechanical vibrations, heat vibrations, or electrical currents. Consequently, knowing the two first to be modes of motion, it is fair to assume that an electrical current is a mode of motion, the manner of which is at present unknown; but that there is a molecular disturbance in each case is evident from the experiments shown.

*Neutrality.*

If I take this bar of soft iron, introduce it in the coil, and pass a strong electric current through the coil, you notice that it is intensely magnetic, holding up this large armature of iron and strongly deflecting the observing needle. I now interrupt the current; the armature falls, and the needle only shows traces of the previous intense magnetisation.

What has become of this polarity? Or what has caused this sudden neutrality? Coulomb supposes that the magnetic fluids have become mixed in each molecule, thus neutralising each other. Ampère supposes that the elementary currents surrounding each molecule have become heterogeneous. De La Rive, Wiedermann, Weber, Maxwell, and all up to the present time have accounted for this disappearance as a case of mixture of polarities, or heterogeneous arrangement.

My researches proved to me that neutrality has a symmetrical arrangement. I stated this in my paper upon the "Theory of Magnetism" to the Royal Society last year. I have since made a long series of researches upon this question, and my

Digitized by Google

paper upon the subject will shortly be read at the Royal Society. This paper will demonstrate beyond question (1st) That a bar of iron under the influence of a current or other magnetising force is more strongly polarised on the outside than in the interior; that its degree of penetration follows the well defined law of inverse squares up to the saturation point of each successive layers. (2nd) The instant that the current ceases a reaction takes place, the stronger outside reacting upon the weaker inside, completely reversing it, until its reversed polarity exactly balances the external layers.

We might here suppose that there existed two distinct polarities at the same end of a neutral bar; but this is only partially true, as the rotation of the molecules from the inside to the exterior is a gradual well-defined curve, perfectly marked.

We see from this that in a large solid bar the reversed polarity would be in the interior, but in a thin bar under an intense field the reversed polarity would be on the outside. Thus, a bar which had previously strong north polarity under a strong external influence, would, the instant it formed its neutrality, have a strong north polarity in the interior, covered or rendered neutral by an equal strong south exterior, the sum of both giving the apparent neutrality that we notice.

I must refer all interested upon this question to my paper shortly to be read; but I will make a few experiments to demonstrate this important fact.

If I take this piece of soft steel and magnetise it strongly, it has a strong remaining magnetism, or only partial neutrality. If I now heat this steel to redness, or put it into a state of mechanical vibration, the remaining magnetism almost entirely disappears, and we have apparent neutrality. This piece of steel being thin, ½ milimetre, I know that the outside is reversed to its previous state. I place this piece of steel in a glass vase near the observing needle, and at present there seems no polarity. Now pour dilute nitric acid upon it, filling up the vase. The exterior is now being dissolved, and in a few minutes you will see a strong polarity in the steel, as the exterior reversed polarity is dissolved in the acid. (Experiment shown.)

Let us observe this by a different method. I take two strips of hard iron, and magnetise them both in the same direction. If I place them together and then separate them, there seems no change, although in reality the mere contact produced a commencement of reversal. Let us vibrate them whilst together, allowing the molecules greater freedom to act as they feel inclined; and now, on separating, we see that one strip has exactly the opposite polarity to the other, both extremely strong, but the sum of which, when placed together, is zero, or neutrality. (Experiment shown.)

Let us take two extremely soft strips, placed together, and magnetised whilst together; on withdrawal of the inducing force the rods are quite neutral. (Experiment shown.)

We now separate these strips, and find that one is violently polarised in one direction, whilst the other is equally strong in the reversed, the sum of both being again zero.

We might suppose that the reaction is due to having separate bars. I will now demonstrate this by magnetising this large ¾in. bar with a magnetising force just sufficient to render the rod completely neutral when held vertically or under the earth's magnetic influence. (Experiment shown.)

You notice that it is absolutely neutral, all parts, as well as the ends, showing not the slightest trace of polarisation. I reverse this bar, and you perceive that it is now intensely polarised. This is due to the fact that the earth's influence uncovers or reverses the outside molecules, and consequently they are now of the same polarity as its interior. Upon again reversing this rod, the magnetism again disappears, and reappears if turned as previously. We have thus a rod which appears intensely magnetic when one of its ends is lowermost, whilst, if that same end is turned upwards all traces of magnetism disappear. These and several other demonstrations which I shall now show you (proving the enormous influence which thickness of a bar has in the production of neutrality or its retention of magnetism) are simple lecture demonstrations. For the complete proof of my discovery of neutral curves I must refer you to my forthcoming paper upon this subject, to be read next Thursday at the Royal Society. (Experiments shown proving the great influence of a thickness of a bar upon its retentive and neutral powers.)

*Inertia.*

I have remarked in my researches that the molecules have true inertia, that they resist being put in motion, and if put in motion will vanquish an opposing resistance by their simple momentum. To illustrate this, I take this large ¾in. bar, and magnetise it so that its south pole is at the lowest end. We know that the earth's influence is to make the lower end north. I now gently strike it with a wooden mallet, and the rod immediately falls to zero. I continue these blows, but the rod obstinately refuses to pass the neutral line to become north, the reason being that in so doing it would have to change the whole internal reversed current that I have discovered. It requires now extremely violent and repeated blows from the mallet to make it obey the earth's influence. Let us repeat this experiment by starting the molecule rapidly in the first instant; the rod is now magnetised south as before. I give one single sharp tap, the molecules run rapidly round, pass through neutrality, breaking up its curve, and arrive at once to strong north polarity. (Experiment shown.)

A very extraordinary effect is shown if we produce this effect by electricity; it then almost appears as if electricity itself had inertia. I take this bar of hard iron and magnetise it to a fixed degree. On the passage of the current you notice that the magnetism seems to be increased as the needle increases its arc, but this is caused by the deflection of the electric current in the bar. The current is now obliged to travel in spirals, as my researches have proved to me that electricity can only travel at right angles to the magnetic polar direction of a molecule; consequently, in all permanent magnets the currents must pass at right angles to the molecule, and its path will be that of a spiral. Let us replace this bar by one from a similar kind of iron, well annealed. The molecules here are in a great state of freedom. We now magnetise this rod to the same degree as in the previous case. The electric current now, instead of being deflected, completely rotates the molecules, and the needle returns to zero, all traces of external magnetisation having ceased. The electricity on entering this bar would have been forced to follow a tortuous circular route; its momentum was, however, too great for the molecules, and they elected to turn, allowing the electricity to pass in a straight line through the bar. Thus, in the first instant, magnetism was the master directing the course of the current; in the last it became its servant obeying by turning itself to allow a straight path to its electric master. (Experiment shown.)

*Superposed Magnetism.*

It is well known that we can superpose a weak contrary polarity upon an internal one of an opposite name. I have been enabled thus to superpose twenty successive stratas of opposite polarities upon a single rod by simply diminishing the force at each reversal. I was anxious to prepare a steel wire, so that in its ordinary state it would be neutral, but that in giving it a torsion to the right, one polarity would appear, whilst a torsion to the left should produce the opposite polarity. This I have accomplished by taking ordinary soft steel drill wire, and magnetising it strongly, whilst under a torsion to the right, and more feebly with an opposite polarity when magnetised under torsion to the left.

The power of these wires, if properly prepared, is most remarkable, being able to reverse their polarity under torsion as if they were completely saturated; and they preserve this power indefinitely if not touched by a magnet. It would be extremely difficult to explain the action of the rotative effects obtained in these wires under any other theory than that which I have advanced; and the absolute external neutrality that we obtain in them when the polarities are changing, we know, from their structure, to be perfectly symmetrical.

I was anxious to show some mechanical movement produced by molecular rotation, consequently I have arranged two bells that are struck alternately by a polarised armature put in motion by the double polarised rod I have already described, but whose position at three centimetres distant from the axis

Digitized by Google

of the armature remains invariably the same. The magnetic armature consists of a horizontal light steel bar suspended by its central axle ; the bells are thin wine glasses, giving a clear musical tone loud enough, by the force with which they are struck, to be clearly heard at some distance. The armature does not strike these alternately by a pendulous movement, as we may easily strike only one continuously, the friction and inertia of the armature causing its movements to be perfectly dead-beat when not driven by some external force, and it is kept in its zero position by a strong directive magnet placed beneath its axle.

The mechanical power obtained is extremely evident, and is sufficient to put the sluggish armature in rapid motion, striking the bells six times per second, and with a power sufficient to produce tones loud enough to be clearly heard in all parts of the hall of the institution.

There is nothing remarkable in the bells themselves, as they evidently could be rung if the armature was surrounded by a coil, and worked by an electric current from a few cells. The marvel, however, is in the small steel superposed magnetic wire producing by slight elastic torsions from a zingle wire, one millimetre in diameter, sufficient force from mere molecular rotation to entirely replace the coil and electric current. (Experiment shown, by ringing the bells by the torsion of a small $\frac{1}{16}$ in. wire, placed four inches distant from bell hammer.)

*Correlation of Forces.*

There is at present a tendency to trace all physical forces to one, or rather a variation of modes of motion. In my last experiment the energy of my arm was transformed in the wire to molecular motion, producing evident polarity ; this, again, acted upon the ether, putting the needle hammer into mechanical motion. This, by its impact upon the glass bells, transformed its motion into sonorous vibrations ; but this does not mean that we can convert directly sonorous vibrations into magnetism, or *vice versâ*.

Let us take this soft iron rod. It seems quite neutral, although we know that the earth's magnetism is trying to rotate its molecules to north polarity at its lowest extremity. We now put it in mechanical vibration by striking it gently with a wooden mallet ; the molecules at once rotate, and we have the expected strong north polarity.

Let us repeat this experiment by employing heat, and here again at red heat an equal strong north polarity appears.

Again we repeat, and simply pass an electric current, of no matter what direction. Again the same north pole appears. Thus, these forces must be very similar in nature, and may be fairly presumed to be vibrations or modes of motion, having no directive tendency, except a slight one, as in the case of electricity, for the same three forces render the rod perfectly neutral, even when previously magnetised, when placed in a longitudinally neutral field, as east and west.

Motion of the molecules gives rise to external magnetism to a rod previously neutral, or renders it neutral when previously magnetised ; in other words, it simply allows the molecules to obey an external directing influence ; the only motion, therefore, is during a change of state or polarity. If there is constant polarity there is no consequent motion of the molecules ; in fact, the less motion of any kind that it can receive, the more perfect its retention of its previous position. Consequently, constant magnetism cannot be looked upon as a mode of motion, either vibrating or rotary ; it is an inherent quality of each molecule, similar in its nature to its chemical affinity, cohesion, or its polar power of crystallisation. A molecule of all kinds of matter has numerous endowed qualities ; they are inherent, and special in degree to the molecule itself. I regard the magnetic endowed qualities of all matter or ether to be inherent, and that they are rendered evident by rotation to a symmetrical arrangement in which their complete polar attractions are not satisfied.

Time will not allow me to show how completely this view explains all the phenomenon of electro-magnestism, diamagnetism, earth currents, in fact all the known effects of magnetism up to the original cause of the direction of the molecules of the earth. To explain the first cause of the direction of the molecules of the earth would rest altogether upon assumption as the first cause of the earth's rotation, and of all things done to the inherent qualities of the molecules themselves.

The mechanical theory of magnetism which I have advocated seems to me as fairly demonstrable as the mechanical theory of heat, and it gives me great pleasure to have been allowed to present you with my views on the theory of magnetism.

## THE ELECTRIC RAILWAY AT BRIGHTON.

At the end of this month, or the beginning of April, in readiness for the Easter visitors, it is expected that the Brighton Electric Railway Extension will be opened. We have on more than one occasion called attention to Mr. Volk's successful experiment, but it must be remembered that too great attention cannot be given to the first successful enterprises in novel directions. True it is that electrical railways have been constructed and are maintained in other countries, but Brighton was the first place in Great Britain to witness an experiment upon a practical scale. On July 1st, 1883, the first application was made to the Brighton authorities showing a desire to test the feasibility of such a railway, and on July 20th permission was given to Mr. Volk by the authorities to carry out the scheme he had explained to them. The railway was opened on August 2nd, 1883, and continued working till January 4th, 1884, when the old road was taken up in order to allow of an alteration in the gradient for the new road. It may be well to remind readers of a few of the details relating to last year's experiment. The line started opposite the Aquarium and ended at the Chain Pier—a quarter of a mile in length—having a 2ft. gauge, with flanged rails, 20lbs. to the yard, fastened with spikes. Longitudinal sleepers 9in. by 3in. were used, formed by cross pieces, with frames of 16ft. section. The resistance of the line was about ·05 ohm. The total resistance of the external circuit was about ·55 ohm. A $D_5$ Siemens dynamo was used to generate the current, driven by an Otto gas engine of two horse-power nominal, giving some three horse-power on the brake. The sleepers were coated with Stockholm tar, which acted as an excellent preservative against the absorption of wet, the loss by leakage in rainy weather being only about 5 per cent. The $D_5$ machine gave a current of some 25 amperes, with an E.M.F. of 50 volts. The drainage was almost perfect, the sleepers being laid upon the shingle, parallel with the road. During the six months the road was working, 30,000 travellers were carried. The car accommodated ten persons, the motor receiving the current and actuating the car, and the conductor. It may naturally be supposed that the greater number of passengers were carried during the warm weather, yet we have reason to believe that at no time was business so slack that the working expenses were not paid, together with depreciation and a small margin of profit.

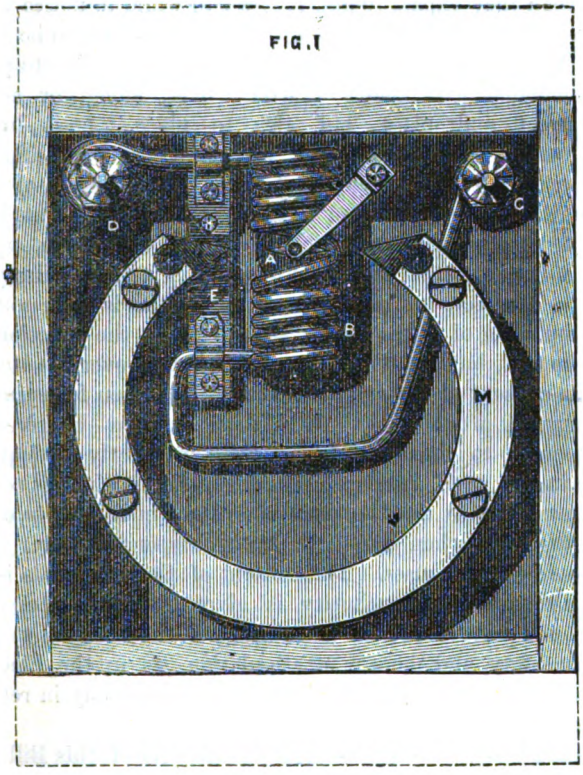
The 1884 railway will start from the same place, where a terminal station has been built, and will be continued under the Chain Pier, and onward parallel with the Madeira-road to the free pier, a distance of nearly a mile. The sleepers will be creosoted, 9in. × 3in. × 4ft. 6in. transversely, being 3ft. distant, centre to centre. The gauge of the new line is 2ft. 9in., with rails, similar to those of last year, of iron because of its greater conductivity. The gradient under the Chain Pier is 1 in 40 ; beyond that the road is approximately level. The generator and engine will be placed in a vault in the sea wall opposite Paston-place, close by which a flight of steps will be appropriated in order to have an inclined railway leading up from the Madeira-road to the Marine Parade. This lift—for it is hardly fair to call it a railway—will have a gradient of 1 in $2\frac{1}{2}$, and will be actuated by hydraulic apparatus, and controlled by electricity. But more of this anon. The generator and motor to be used will be those of Siemens, known as $D_2$ machines. The car, which has been carefully designed, and is to be of great elegance, will hold 18 passengers inside and six on each footboard, or a total of 30. The motor will be an

Digitized by Google

Otto gas engine of eight horse-power. We have thus given the briefest possible outline of what has been done, and what it is proposed to do, trusting to be able to give fuller details, with illustrations, when the line is opened. The electric railway will form one of the chiefest attractions to Brighton, and we hope the authorities will not only support the work, but will endeavour still further to increase its utility and attractiveness by extending it in the one direction to the Downs, in the other to the Grand Hotel, or even still further towards Hove.

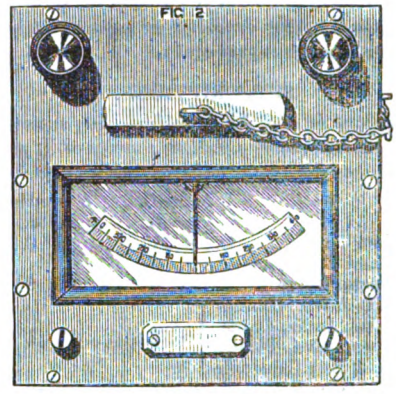
## THE CONSOLIDATED ELECTRIC COMPANY.

When electric lighting became possible it was seen that there would probably be a large demand for apparatus of various kinds required in carrying out electric light work. The Consolidated Company was formed some twelve months or more since to manufacture such apparatus. Specimens of their work



Interior of Ammeter.

have been sent to us for notice. The fact that this is a manufacturing company places it in a somewhat different category to those companies floated merely for the sake of speculative purposes. The shareholders anticipate a demand for the wares produced; but they ought, at the same time, to consider that production alone will not lead to success. The demand has to be created, and the goods have to be made as cheaply and as good as they can be obtained elsewhere. If we might venture upon a criticism we should say do not look upon these pieces of apparatus as objects of patents. There is hardly—we will not go so far as to say there is not one—a piece of apparatus that cannot be made in two or twenty thousand different designs, and a patent is little or no protection. Let the designs be well considered, the parts made wholesale and interchangeable, and, with good salesmen, a large business should be done. The apparatus constructed by the Consolidated Company has been almost throughout designed with a view to comply with the requirements of the Board of Trade. It seems, indeed, that these requirements have been kept in view throughout, so that the varied necessities of any installation might be obtained in a most complete and efficient state. The company manufacture secondary batteries of the B.T.K. type, so called from the initial letters of the inventors' names—Beeman, Taylor, King. We are not prepared to give an opinion as to the merits of these batteries, not having had them under investigation. The plates are really a modification of the well-known Planté plate, the view of the inventors being that the most important requirement of a secondary battery is extended surface and continuity of conduction. To obtain these a long strip or ribbon of lead is taken and wound round and round itself till a sufficiently large plate is formed.



Exterior of Ammeter.

There are other details, but as we shall illustrate a plate sent us for that purpose, we shall leave this part of the subject for the present. A specimen of the apparatus constructed is shown in Figs. 1 and 2, which represent a cheap ammeter. The terminals are shown at C and D. A large horseshoe magnet, M, has a directive influence up a smaller magnet A,

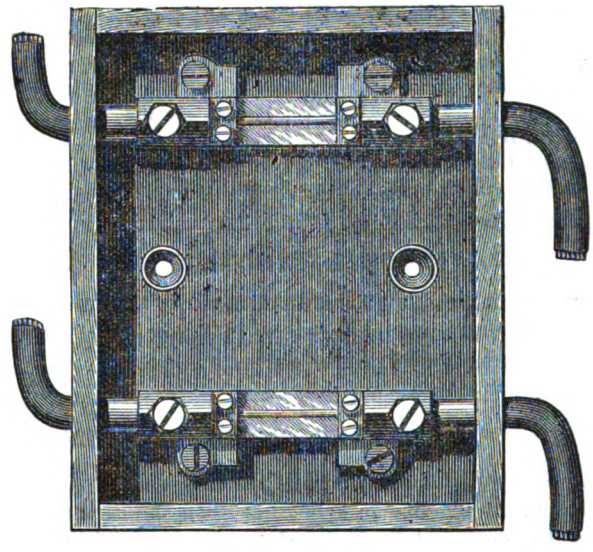


Fig. 3.—Cut Out.

which again will be under the influence of a current through the coil B.

It is unnecessary to say more of this instrument, except that the case is carefully made in order to keep the interior free from dust. Fig. 3 shows a cut out. There is nothing peculiar in this, the terminals merely being joined by a fusible plug of such size and composition as to fuse when the current exceeds a certain predetermined quantity. This apparatus, though it may seem, and indeed is, very simple, is at the same time one of the most important in electric light work, for upon its efficiency depends freedom from dangers of fire, destruction of wire, &c.

## THE VESTRIES AND OVERHEAD WIRES.

The Vestry of Chelsea, which showed such praiseworthy activity and intelligence in reporting upon the Electric Lighting Act, has been equally energetic and successful in meeting the proposed legislation in respect to telephone wires. The report of Messrs. Mossop and Stayton, the vestry's advisers, is at once fair in tone and conclusive in argument. Nothing in the extracts we printed last week can be construed as making a dead set against the extension of telephone wires. "The public are impressed much more by the occasional dangers or risks incurred from wires being suspended without proper supervision, or left to decay, or unowned, than by the immense advantages which attend the use of efficient wires." A document which makes this candid declaration, and which adds the further admission that "overhead wires might with proper supervision be rendered safe," cannot be accused of prejudice, and any objections which the writers may make to the scheme under consideration are therefore entitled to a patient hearing. The grounds on which the paragraph we have quoted has been framed, and the conclusion that the local authorities might under certain conditions give consent to a limited use of overhead wires "rather than insist on the use of underground wires only at a thirty-fold (*sic*) increase of the outlay," is based on a misunderstanding; but it shows that the advisers of the Chelsea Vestry have taken into account public policy, and are not inclined to sacrifice it to merely local interests.

This being so, it is important to notice the grave objections which the report raises against the Bill put forward by the United Telephone Company. It is not worth while to discuss that Bill in detail. The Metropolitan Board of Works are going to offer it a strenuous opposition. The Vestry of St. James's, Westminster, is of one mind with that of Chelsea, and it is probable that other vestries will join them. There is therefore no chance of the Bill passing in its present shape; but as the tactics of framers of such Bills are often designed to get all that they want by first asking a great deal more than they expect to get, it is worth while to notice some of the powers which this modest scheme professes to be seeking. Not only do the company demand to be able to place any telephone wire under a street, over, along, or across any street and place, but also to place "posts in or upon any street;" not only are they to be allowed to "break up any street and alter the position of any gas or water pipe (not being a main) thereunder," but likewise to place and maintain telephone wires "in, upon, over, along, or across any land or building or any railway or canal." The consent of the local authorities is to be sought for the placing of wires under the street or the erection of posts upon it, but not for the erection of wires over the street; and the consent of the vestry appears to be taken for granted, as Clause 10 provides that three days' "notice" be given of an intention to break up any street—an utterly inadequate notice in any case. The only circumstance in which it seems to be necessary to ask the vestries' consent in respect to overhead wires is when they are to be suspended lower than the fronts of the houses. The consent of the occupants is in no case required; no authority is given to the vestries to compel adequate inspection and testing of the wires in regard to their safety, and there is no stipulation, as in the Electric Lighting Bill, restricting the charges of the company in return for these extraordinary concessions.

The high-handed conduct of the promoters of this Bill has been the subject of much animadversion during the past twelve months; if anything were wanting to confirm the justice of these public complaints it would be furnished by the preposterous pretensions of this Bill. Evidently the company have persuaded themselves that they are public benefactors—a sort of State department working for the benefit of the commonwealth, and only hindered completing their mission by certain wrong-headed vestrymen or over-æsthetic householders. It is time they were disabused of this illusion. As a fact, they are working simply for profit, and to increase this profit is the object stamped on every clause of their Bill. All their self-imposed regulations as to inspection and the like are so much dust thrown into the public's eyes. The wires are theirs, and theirs alone should be the responsibilities. Inspection from outside would only shift the responsibility; and, as they are not a public department whose profits go into the pockets of the taxpayers, they ought to pay the local taxes, like every other trading community, instead of asking for powers which practically place them above and beyond the reach of such obligations. The simple facts of the situation are these. A few years ago some overhead wires existed in London, but were gradually

Digitized by Google

being reduced in number. Taking advantage of popular admiration and astonishment, the proprietors of the telephone have increased those wires a thousandfold—a hundred thousandfold—and have done it with a flagrant disregard of public decency, to say nothing of public safety. They had no legal right to do this, and the only excuse for having done it is that the legal right to prevent it was not easily discoverable. The offenders now ask for legal rights to go on doing what everybody protest against their ever having done at all.

The one sole justification for these overhead illegalities is the additional cost of laying them underground. But the extra cost is grossly exaggerated. The Chelsea Vestry has been obviously misled on this point. There can be no serious objection to overhousetop wires—that is to say, wires and cables carried along and affixed to the roofs or gutters of street buildings; the objection is to their crossing the thoroughfares overhead when the extra cost of cabling them and putting them in proper receptacles *under* the streets would be comparatively small. The argument from economy concedes too much. A walk from Aldgate to Charing-cross will show what economy has done. Not content with crossing the streets at direct angles, the telephone companies have carried their wires at as wide an angle as is practicable, with the result that many streets have hundreds of wires running practically parallel with the roadways. Can it be proved that the companies' charges necessitated this economy? We suspect not: and we urge upon the vestries, or preferably the Metropolitan Board of Works on their behalf, to be satisfied with nothing less than that the existing wires, and all future additions to them, wherever they must cross the street, be collected into subways under it. This is practicable, and it is not prohibitive in point of cost. The Postmaster-General it seems to us is not free from responsibility in this matter. He gets ten per cent. of the company's earnings; and if, as is now alleged, the wires revert to him at the end of thirty-one years, it is clearly his duty to exercise a vigilant control over their erection; failing this the vestries should take the matter into their own hands, and test their authority in a court of law. In any case they must insure the rejection of this audacious scheme which treats both the vestries and the public as if they had no rights whatever.

## THE THEORY OF DYNAMO-ELECTRIC MACHINES.

(CONCLUDED FROM PAGE 302.)

### 11. *Application of Results to Determine the Work Done by Mechanical and Electromotive Forces.*

We now return to equations (17) and (18), which were found in Section 8, to determine the work done by the mechanical and electromotive forces in the case of a stationary coil; the first being subsequently modified, in Section 9, to suit the case of a rotating coil, by substituting the product $M P_2$ for the product $N P_1$. If in these equations we substitute for $P_1$ and $P_2$ the magnitudes $P_1''$ and $P_2''$, as found in the last section, they become

$$\left.\begin{aligned} T &= -h M N v - k M P_2'' r \\ E i &= h M N r + k N P_1'' v - \rho i^2 r \end{aligned}\right\} \quad . \quad . \quad . \quad (27).$$

Replacing $P_1''$ and $P_2''$ by their values from equation (26), we obtain

$$\left.\begin{aligned} T &= -MN\left(h + \frac{kC}{1+\beta i}\right) r - kM^2\left(\eta + \frac{\epsilon' C}{1+\beta i}\right) v^2 \\ E i &= MN\left(h + \frac{kC}{1+\beta i}\right) v - \rho i^2 r - kN^2\left(\eta + \frac{\epsilon' C}{1+\beta i}\right) v^2 \end{aligned}\right\} (28).$$

Lastly, we have to substitute for M and N in these equations their values as given in equations (12) and (13), viz., $M = \frac{A i}{1+\alpha i}$, $N = B i$.

This enables us to divide the second equation by $i$, and we obtain

$$T = -\left[\frac{AB}{1+\alpha i}\left(h + \frac{kC}{1+\beta i}\right) v + \frac{k A^2}{(1+\alpha i)^2}\left(\eta + \frac{\epsilon' C}{1+\beta i}\right) v^2\right] i^2 \text{ (I.)}$$

$$E = \left[\frac{AB}{1+\alpha i}\left(h + \frac{kC}{1+\beta i}\right) v - \rho v - kB^2\left(\eta + \frac{\epsilon' C}{1+\beta i}\right) v^2\right] i \text{ (II.)}$$

These are the two equations which must form the basis of all further investigations.

To make them simpler and more handy for calculation, we may introduce new constants, defined as follows:—

$$\left.\begin{aligned} a &= \frac{1}{\alpha} \\ b &= \frac{1}{\beta} \\ p &= \frac{h A B}{\alpha} \\ q &= \frac{k A B C}{\alpha \beta} \\ l &= \frac{A}{B \alpha} \\ \sigma &= k B^2 \eta \\ \lambda &= \frac{k B^2 C \epsilon'}{\beta} \end{aligned}\right\} \quad . \quad . \quad . \quad . \quad . \quad . \quad (30)$$

Then the equations take the following form:—

$$T = -\left[\frac{1}{a+i}\left(p + \frac{q}{b+i}\right) v + \left(\frac{l}{a+i}\right)^2\left(\sigma + \frac{\lambda}{b+i}\right) v^2\right] i^2 \text{ . (Ia).}$$

$$E = \left[\frac{1}{a+i}\left(p + \frac{q}{b+i}\right) v - \rho v - \left(\sigma + \frac{\lambda}{b+i}\right) v^2\right] i \text{ . . (IIa).}$$

### 12. *Determination of the Intensity of the Current Generated by a Machine, when no foreign Electromotive Force joins in the action.*

If the external wires, by which the circuits belonging to the machine itself are closed, have no other E.M.F. contained in them, so that the E.M.F. induced in the rotating coil, which we have called E, is the only E.M.F. in the whole circuit, then by Ohm's law we have (if R is the total resistance of the circuit)

$$E = R i;$$

whence equation (II*a*) becomes

$$R i = \left[\frac{1}{a+i}\left(p + \frac{q}{b+i}\right) v - \rho v - \left(\sigma + \frac{\lambda}{b+i}\right) v^2\right] i \text{ . (31)}$$

Dividing by $i$, and collecting the integral terms on the left hand side, we have

$$R + \rho v + \sigma v^2 = \frac{1}{a+i}\left(p + \frac{q}{b+i}\right) v - \frac{\lambda}{b+i} v^2$$

or

$$1 = \frac{1}{a+i}\left(p + \frac{q}{b+i}\right)\frac{v}{R + \rho v + \sigma v^2} - \frac{\lambda}{b+i}\frac{v^2}{R+\rho v+\sigma v^2} \text{ (32).}$$

If for shortness we put

$$w = \frac{v}{R + \rho v + \sigma v^2} \quad . \quad . \quad . \quad . \quad . \quad . \quad (33)$$

the equation becomes

$$1 = \frac{1}{a+i}\left(p + \frac{q}{b+i}\right) w - \frac{\lambda}{b+i} v w \quad . \quad . \quad . \quad (34).$$

From this equation the intensity $i$ of the current generated by the machine can be determined. Multiplying by $(a + i)$ and $(b + i)$, and arranging according to powers of $i$, we have

$$i^2 - (p w - \lambda v w - a - b) i - (p b + q) w + \lambda a v w + a b = 0. \text{(35).}$$

Digitized by Google

Solving this quadratic equation, we obtain

$$i = \tfrac{1}{2}(p w - \lambda v w - a - b) \pm \tfrac{1}{2}\sqrt{(p w - \lambda v w - a - b)^2 + 4(p b + q) w - 4\lambda a v w - 4 a b}. \quad (36).$$

The value with the positive sign in the root is alone applicable, as the other gives negative values of $i$ for all values of $v$, whereas in equation (34) $i$ only occurs in the denominator, and expresses the absolute value of the current intensity—a quantity essentially positive. Taking the positive sign, all values of $v$ above a certain limit give positive values of $i$, while values below that limit give negative values to $i$. The latter point we will discuss hereafter.

The foregoing equation may also be written as follows:—

$$i = \tfrac{1}{2}(pw - \lambda r w - a - b) + \tfrac{1}{2}\sqrt{(pw - \lambda r w + a - b)^2 + 4(q - pa + pb)w} \quad (37)$$

If for simplicity we put

$$w' = w\left(1 - \frac{\lambda}{p} v\right) = \frac{v - \frac{\lambda}{p} v^2}{R + \rho v + \sigma v^2} \quad . \quad . \quad . \quad (38)$$

$$c = q - p a + p b \quad . \quad . \quad . \quad . \quad . \quad . \quad (39)$$

we arrive at the following simple form:

$$i = \tfrac{1}{2}(p w' - a - b) + \tfrac{1}{2}\sqrt{(p w' + a - b)^2 + 4 c w}. \quad . \quad (40)$$

To gain some idea of the conditions of the magnitude $i$, as thus determined, we may proceed as follows:—The constant $c$, given in equation (39), may be either positive or negative according to the construction of the machine, and can of course also have the value zero. In this latter case the square root and the quantity $a$ disappear, and we have

$$i = p w' - b \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad (41)$$

If the values of $i$, given by this equation, are represented by ordinates, and those of $w'$ by abscissæ, we obtain a straight line cutting the axis of $x$ at the point for which the abscissa $= \frac{b}{p}$, and thence rising at an angle whose tangent $= p$.

If $c$ is not = zero, we may express $w$ in terms of $w'$, so as to make $i$ a function of $w'$ only. If we then express $i$ graphically as before, we obtain a curve which deviates from the previous straight line by so much the more as the absolute value of $c$ is greater, the point at which it cuts the axis of $x$ varying, and the curvature being in the one or the other direction, according as $c$ is positive or negative. The curvature, however, is slight, and decreases as $w'$ increases.

If the intensity of current $i$ is to be referred direct to the number of revolutions $v$, we must replace $w$ and $w'$ by their values given in (33) and (38). It must be noted that these values have R in the denominator, which indicates how the current intensity depends on the resistance of the wires, and how, in consequence of the terms containing $\rho$, $\sigma$, and $i$ as factors, it increases more slowly than the velocity $v$: this is especially striking with high values of the velocity.

### 13. *Action of the Machine.*

It has just been remarked that equation (36), even with the positive sign to the square root, and equation (40) in like manner, give for small values of $v$ negative values of $i$, which are inadmissible. This must not be taken to imply that the fundamental equation (II$a$), from which we started, gives incorrect results when the speed of rotation is small. We must remember that this equation led first to equation (31); and that it was only after dividing this equation by $i$ that we obtained the quadratic equation (35), whose solution is given in (36). If we had not so divided, we should have had, instead of a quadratic, a cubic in $i$, which besides the roots given in (36) would have had a root = 0. This zero value must be taken as one of the values given by the fundamental equation, and is the value to be used in the cases when the two other values are inadmissible.

If then, even with low speeds of rotation, we adhere strictly to equation (II$a$), we arrive at the following conclusions:—For such low speeds the machine produces no current; its action only begins when a certain speed is attained, and then as the speed rises the intensity of the current rises also in a definite proportion to the differences in speed. This is so much in accordance with experience that a special name has been introduced for the interval during which the machine does not act, the earlier turns of the machine, up to a certain speed, being known in Germany as the "dead turns."

In strict accuracy, however, we should not apply the equation (II$a$) to cases of very low speeds, for which it gives the value $i = 0$; since in such cases the remaining magnetism in the iron of the fixed electro-magnets ought to be taken into consideration, as explained in Section 7. From our fundamental equations we have deduced the value of the magnetic moment of the fixed electro-magnet as follows:—

$$M = \frac{A i}{1 + a i}.$$

This equation gives for small values of $i$ correspondingly small values of M, and if $i = 0$, M = 0. If, however, before the action of the current begins, there is a certain amount of magnetism in the iron, this must clearly be taken into account when we come to determine the magnetism in the case of weak currents. It would be hard to say how this can be done with the highest possible degree of accuracy, but for our purposes an approximation will be sufficient. Thus, let $\mu$ be the moment (assumed small) of the remaining magnetism, and let us find the value of $i$, for which the expression given above for M assumes the value $\mu$. If $i_1$ be this value of $i$, we must have

$$\mu = \frac{A i_1}{1 + a i_1}$$

whence

$$i_1 = \frac{\mu}{A - a\mu} \quad . \quad . \quad . \quad . \quad . \quad . \quad (42)$$

We may then lay down that, for all values of $i$ which are smaller than $i_1$, the equation to be applied for determining the magnetic moment M is

$$M = \mu,$$

and for all values of $i$ greater than $i_1$, it is

$$M = \frac{A i}{1 + a i}.$$

This shows us also the method to be employed in order to find the current existing during the action of the machine. At first we must treat it as a magneto-electric machine, of which the fixed magnet has the small moment $\mu$. Such a machine does, indeed, generate currents, even at low speeds of rotation, and the intensity increases with the speed; but on account of the smallness of $\mu$ this increase is very slow. When the speed has reached such a point that the intensity has the value $i_1$, then the machine also acts as a dynamo-electric machine, in which the fixed magnet has the moment $\mu$, and generates a current of the same intensity $i_1$; and from henceforward we may apply, to determine the intensity, the fundamental equation (II$a$) as deduced for a dynamo machine.

The question then arises, what is this speed of rotation at which the machine, whether taken as a magneto or dynamo machine, gives a current of one and the same intensity $i_1$? We may call this value $v_1$; and to find it, we must replace $i$ by $i_1$ in equation (40). At the same time we must replace $w$ and $w'$ by $w_1$ and $w_1'$, these being the values which correspond to the value $v_1$ for $v$. We thus obtain

$$i_1 = \tfrac{1}{2}(p w_1' - a - b) + \tfrac{1}{2}\sqrt{(p w_1' + a - b)^2 + 4 c w_1}$$

whence

$$(a + i_1) p w_1' + c w_1 = (a + i_1)(b + i_1) \quad . \quad . \quad . \quad . \quad (43)$$

In order from hence to determine $v_1$, we have only to replace $w_1$ and $w_1'$ by their values as given in (33) and (38), viz.:—

$$w_1 = \frac{v_1}{R + \rho v_1 + \sigma v_1^2}, \qquad w_1' = \frac{v_1 - \frac{\lambda}{p} v_1^2}{R + \rho v_1 + \sigma v_1^2}$$

Here we will make an approximate determination only for $v$. The terms containing the small factors $\lambda$ and $\sigma$ are important only at very high speeds, and therefore, at the low

Digitized by Google

speed now under consideration, may be neglected. Thus, we may put

$$w_1' = w_1 = \frac{v_1}{R + \rho v_1}$$

whence $$\frac{v_1}{R + \rho v_1} = \frac{(a + i_1)(b + i_1)}{p(a + i_1) + c}.$$

Solving this equation,

$$v_1 = \frac{(a + i_1)(b + i_1) R}{p(a + i_1) + c - (a + i_1)(b + i_1)\rho}. \quad . \quad (44)$$

In ordinary cases of practice we may simplify this still further. The magnetic moment, $\mu$, of the remaining magnetism is so small that the intensity of current $i$ is quite insignificant as compared with that which exists with the machine at full work; and in practical work it is customary, as already mentioned, to neglect the current which exists at low speeds and rises slowly to intensity $i_1$, treating the generation of current as if it began abruptly at a particular speed. On this method we take for this speed the limiting value assumed by the velocity, when $\mu$, and therefore also $i_1$, approach zero. If this limiting value of $v_1$ be called $v_0$, the above equation (44) becomes

$$v_0 = \frac{a b R}{p a + c - a b \rho}, \quad . \quad . \quad . \quad . \quad . \quad . \quad (45).$$

which, by equation (39), may be written also

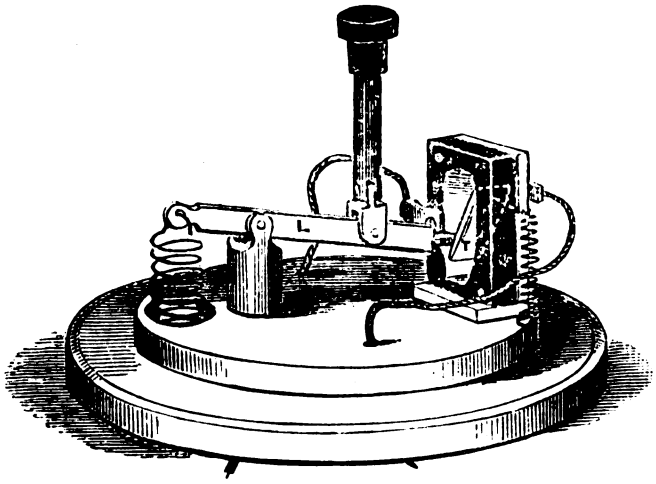
$$v_0 = \frac{a b R}{p b + q - a b \rho}. \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad (46).$$

The value of $v_0$, thus obtained, gives the value of the so-called dead turns.

Here Professor Clausius terminates his labours for the present, but he promises in a future paper to trace the further applications of the fundamental equations here obtained, especially in the direction of the transmission of power by the dynamo machine.

## A NEW SWITCH.

We illustrate below a new form of switch for electric lighting or other purposes, patented by Mr. E. C. Gee. Our illustration, which shows the parts with the woodlen cover removed,



almost explains itself. The circuit is closed by pressing the push which is attached to the lever L. At the end of this lever is the contact piece, which, when it is pushed down, is forced into a suitable notch by the action of the spring attached to the tumbler T. When it is, as shown in the engraving, required to break contact, the push is again depressed, and the contact piece passes below the end of the tumbler piece T. The spring attached to the latter forces it against the side of the arch, and the action of the spring attached to the lever L brings the contact piece back to its normal position ready to be again depressed. Mr. Gee claims for his switch that the contact points cannot remain in such a position as to produce sparking, and that the parts do not readily get out of order.

## CORRESPONDENCE.

### THE PHYSICAL THEORY OF THE GRAMME MACHINE.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: The error into which Mr. Nalder has fallen (p. 306) is not, I think, in any way discreditable to him, since his conclusion is, *prima fâcie*, a tolerably direct consequence of the principle of the conservation of energy to which he refers. I may observe, however, that an inspection of the diagram I gave (p. 178) would have shown him that the current must necessarily be in the opposite direction to that specified by him. The conclusions deduced from the assumption that similar poles repel and opposite poles attract each other are, as Mr. Nalder well knows, frequently erroneous. The fact that the ring cannot be rotated without producing fresh amperian currents ordinarily under conditions in which they can exert electro-dynamic induction upon a closed circuit constitutes of itself a sufficient general vindication of the principle of the conservation of energy in the present case. Some notes of mine which may be found in another column will perhaps aid Mr. Nalder in illustrating that principle more particularly. In regard to the elucidation attempted by "E," I am probably not alone in the failure to extract any meaning from it. Surely he does not intend to convey that the current traversing the coils determines the polarity of the ring, creating a north pole here and a south pole there. Surely, also, there is, in any case, a north pole at D (above the line), and also a north pole at C (above the line).—Yours, &c., DESMOND G. FITZGERALD.

[The article referred to above by Mr. FitzGerald shall appear next week.—ED. *E.*]

TO THE EDITOR OF THE ELECTRICIAN.

SIR: We have recently had from the pen of Mr. Desmond G. FitzGerald an attempt to explain the mechanical generation of electricity by ignoring the "line of force" hypothesis, or, as I will herein call it, *the external magnetic polarity.*

Mr. FitzGerald, however, confines his theory to machines of the Pacinotti type. It is not easy to accept any theory that will not enable the action of all known dynamo-electric machines to be understood. To do this, therefore, we must find some other explanation of magneto-electric phenomena than that propounded by Mr. FitzGerald. In fact, after carefully reading that gentleman's communications, one feels that their author has hopelessly mixed up two distinct theories—as the amperian and the "line of force" theories—sometimes applying one theory when the other should be called in, and *vice versâ*. Moreover, he has, by endeavouring to explain by complicated reasoning that which is in reality beautifully simple, added to the difficulties of his elucidations as to the directions of induced magneto-electric currents under various conditions.

The amperian explanation as to the cause of magnetism has no doubt done good service in electrical science, but there is every reason to think that its days are numbered. There must be precisely the same amount of magnetism round about a straight bar magnet exteriorly as there is in its interior, and if the interior magnetism is the result of molecular electric currents, what is the cause of exterior magnetism? Are there electric currents in air? If so, what is their vehicle? I venture to say that magnetism is as totally independent of the molecules of iron as it is of every other substance, except that iron possesses the capacity of rendering its effects more apparent; and the reason why a bar of steel becomes a magnet is because the magnetism has been, so to speak, put into it, either by nature or its cause, or by man, or both, its retention of that magnetism depending on the molecular rigidity of its mass.

In a straight bar magnet, then, we have *internal* and *external* magnetism. This magnetism develops the phenomenon known as polarity. In no case, however, is the external polarity sensible unless a part of the magnetic circuit acquires its equilibrium in air, *i.e.*, outside of the bar—thus distributed in non-magnetic space. Faraday discovered that when a conductor was made to intersect this external magnetism at right

Digitized by Google

angles to its polarity a current of electricity was generated, the power of such current being proportional to the magnetic strength, the speed at which the conductor moved, and the angle it made with the polar direction. He also showed that so long as the direction of movement was the same, say over a S pole and under a N pole, no matter whether the so-called lines of force were increased or diminished, or whether the conductor was approaching to or receding from the space between the poles, then the current was always in the same direction. If the conductor was moved in the opposite direction, other things being the same, then the direction of current was reversed. There seems to be an impression that in moving a conductor in a magnetic field it is essential to "add" or "subtract" lines of force.

With the exception of a recent statement by Mr. FitzGerald —which I will take leave, in all good feeling, to presently criticise—there has never been a greater fallacy put on record.

It is true that the rotating coils of the Gramme or Siemens (drum) armatures move in a varying magnetic field, but this is an accidental arrangement, resulting from mechanical difficulties that appear to be inseparable from the construction of dynamo-electric machines when comparatively high-tension currents are required.

This fact, probably, has engrafted the idea that it is absolutely essential to "increase and diminish the lines of force" to produce a current. Let us consider what occurs in one of the convolutions of a Siemens or Gramme armature just

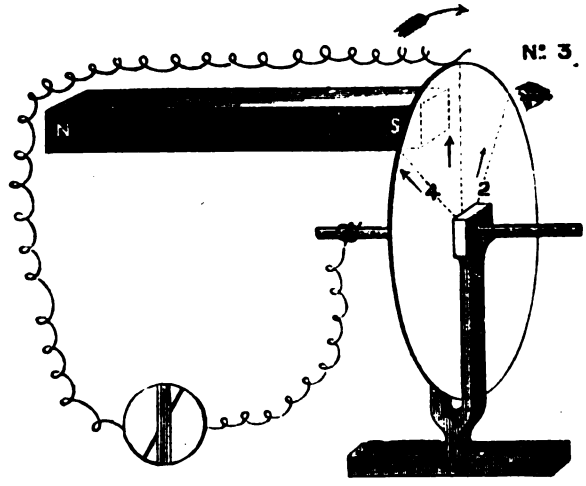


Fig. 1.

after it passes the medial line. The current continues in the same direction until it arrives at the opposite medial line. It is needless to say that in describing this half of a revolution it has approached to, and receded from, a magnet pole, and the lines of force have been both increased and diminished with regard to the convolution, without reversal of current.

The accompanying figures illustrate the application of two definitions which, I think, will be found to explain the direction of the induced current in all known dynamo-electric machines. They consist of the Faraday disc machine, the Ferranti-Thomson, and the Gramme. If space permitted it would be easy to apply the definitions to the Siemens, Floyd-Delafield, Siemens unipolar, Elphinstone-Vincent, &c.

(1) If a conductor or segment of a coil be moved in a direction from *left to right*, between the S pole and your own face, or if it be moved in the opposite direction, from *right to left*, between the N pole and face, the induced current will be in a direction from the chin to the crown of the head.

(2). If a conductor be moved in a direction from *left to right*, between the N pole and the face, or if it be moved in the opposite direction, from *right to left*, between the S pole and the face, then the current will be in a direction from the crown of the head to the chin; no matter whether the "magnetic potential" be increased or diminished with regard to the conductor.

It is, of course, to be understood that the conductor intersects or "cuts" the magnetism at, or nearly at, right angles to the external polarity or "lines of force."

In the figures the feathered arrows denote the direction of mechanical movement, and the plain arrows the direction of current. Fig. 1 is a Faraday disc machine, which is shown to rotate from left to right between a S pole and the face. The current therefore goes from the centre to the circumference of the disc; from the chin to the crown of the head as regards the individual that is looking at it. If rotated from right to left the current is in the opposite direction. If the collector is applied at the dotted lines on either side of the magnet the current is still in the same direction so long as the direction of movement is the same. This fact clearly proves that when a

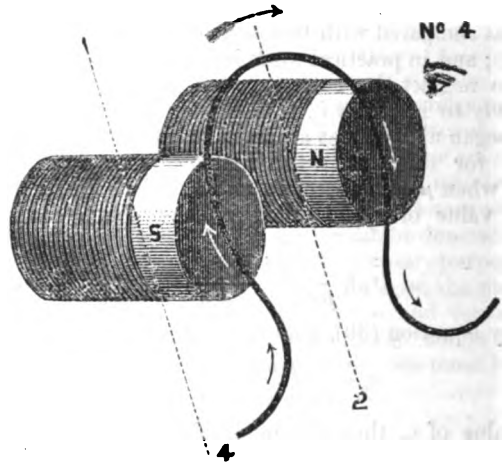

Fig. 2.

wire approaches or leaves a magnet pole there is no change in the direction of the induced current.

Fig. 2 shows one of the loops of a Ferranti armature. The medial line, or the point at which reversibility of current occurs in this machine, is just half way between the axes of the field magnets, as indicated by dotted lines 4 and 2. It is

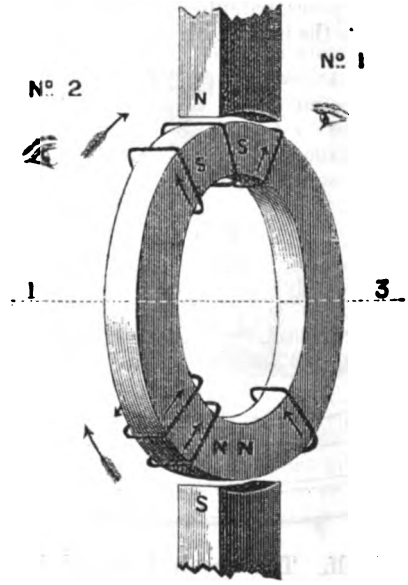

Fig. 3.

easy to identify one side of the loop—that over the S pole—with a radial line of the disc (Fig. 1), and the direction of movement and current is alike in both cases. The opposite side of the loop being between a N pole and the face, and moving from *left to right*, the induced current is, according to the definition No. 2, from the crown of the head to the chin.

Fig. 3 shows a Gramme machine. That part of the armature core at which the eyes are looking is under the inductive effect of a N field magnet, and consequently is of S polarity.

Digitized by Google

From eye No. 1's point of view the coils are moving from *left to right*, and the induced current is therefore in a direction from the chin upwards. From eye No. 2's point of view, however, the coil will be going from *right to left*, and according to the definition of the current will be in a direction from the crown of the head to the chin.

It is hardly necessary to say that the direction of current is the same in the half circle from 1 to 3, shown by the dotted medial line; another proof that the "increase or decrease," or "adding or subtracting lines of force," makes no difference to its direction. By comparing the three machines it will be seen that the mechanical movement is the same in all of them, and the direction of current, as it appears to eyes No. 1, No. 3, and No. 4, is in the same direction. The reason why the current appears in the opposite direction to No. 2 is because *to him* the coil is going from right to left. If the disc in Fig. 1 be rotated from right to left, instead of the direction shown, the current will be in the same direction as it appears to No. 2, and in both cases the conductors are moving over S poles.

The mechanical generation of electricity, then, depends on a conductor intersecting the external magnetism, and this external magnetism is located in its most concentrated form round about the ends of a bar of iron or steel, from which points it diverges and alters its polar direction so as to find its shortest path.

As the polar direction of the external magnetism at the equatorial part of a straight bar is in all probability about parallel with the latter, it follows that if the direction of movement of a conductor is favourable for the production of a current at its ends, it would necessarily be unfavourable for such production at its equatorial part, because in the first case the conductor would be moving at right angles to the external polarity, whilst in the second case it would move in a direction parallel with the latter or *along* the "lines of force."

If this straight bar magnet be formed into a semi-circle so as to represent the half of a Gramme ring, there could then be no external magnetism at the "neutral" part of it, but Mr. Fitz-Gerald says "that the introduction of the *neutral point* of an electro-magnet within a coil is attended with a *greater* inductive effect than that resulting from the insertion of one of its *poles!*" It is not difficult to see that Mr. FitzGerald is confounding the mechanical generation with the electrical production or transformation of electricity. Induction coils do not depend on external magnetism, the chief cause of the secondary current being the magnetic change of the core. To produce the effect in a coil near the medial line of a Gramme ring, it would be necessary to change the magnetism in the core periodically; but it is well known that the magnetism in a Gramme ring is fixed in space, whilst the core percolates through it as it revolves.—Yours, &c., E. L. VOICE.

London, February 22nd, 1884.

---

TO THE EDITOR OF THE ELECTRICIAN.

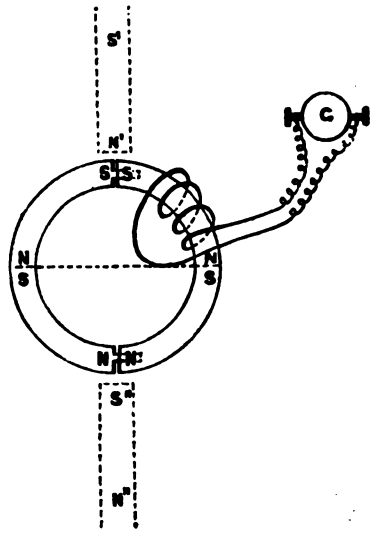
SIR: We endorse Mr. D. FitzGerald's theory, because it points direct to the great defect in the Gramme machine. Any theory of the Gramme machine must account for these three facts:—At the point of (1) maximum effect the brushes collect the (2) useful currents, but (3) wasteful currents are also generated.

Now Mr. FitzGerald's theory accounts for all these facts. It explains that the induced magnetism of the core generates (by induction) the (2) useful currents which are collected, and explains why they are a (1) maximum at the points $\frac{N}{S}, \frac{N}{S}$, and it also explains why (3) wasteful currents are generated.

It is not necessary for me to recapitulate Mr. FitzGerald's arguments. I might say, though, that if any one likes to experiment with the apparatus shown, he will get what represents the useful current of the Gramme machine, while if above S S and below N N he put N′, S″ respectively, he will get what represent the useful current *plus* the wasteful currents, which latter, although they neutralise one another, evidently heat the coils, and, in accordance with the principle of the conservation of energy, work is expended in producing them.

S N S N, S N S N are two semi-circular magnets; N′S′, N″S″ are two bar magnets; G is a galvanometer connected to a coil B.

It would take too long to show how to use the apparatus, but, from what has been written in your paper, we hope your readers will see how, without explanation, experiments made with this apparatus show conclusively that the useful currents are generated by induction from the core, which is magnetised inductively (in the machine), whilst the wasteful currents are



generated by induction from the external poles. Mr. Fitz Gerald shows why the maximum effect is obtained at the points $\frac{N}{S}, \frac{N}{S}$.

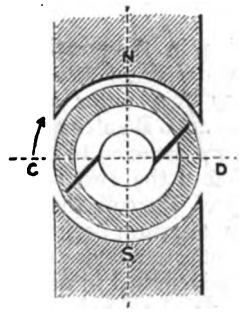
Now, how will "E" or any other supporter of the "lines of force" theory account for these three facts, viz., the generation of the wasteful and useful currents, and the fact that the maximum effect is on the line joining $\frac{N}{S}, \frac{N}{S}$?—Yours, &c.,

S. THORNTON and W. R.

---

TO THE EDITOR OF THE ELECTRICIAN.

SIR: I regret to find that the last paragraph of my letter on the above, which appeared in your issue of the 1st inst., was



rendered nonsensical by the misplacement of two letters C and D on the diagram. I repeat this paragraph, and hand you a simple diagram to illustrate the point to which I refer. "The approaching face of the coil will be a *south* pole, and the current will consequently flow in the opposite direction. To make this evident Mr. Nalder has only to consider that if the current flowed in the direction he assumes, the ring would be magnetised by the current in such a way as to produce a N pole at D and a S pole at C, which would *help* the motion of the machine. The current must flow so as to create a N pole in the ring at C and a S pole at D. This will oppose the

Digitized by Google

motion of the machine, and is in accordance with the principle of the conservation of energy to which he refers."—Yours, &c.,

E.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: To render your correspondent "E" his due, I must acknowledge the correctness of his conclusions respecting the explanation I gave of the Gramme ring, and am sorry to have given any one reason to show error either in method or reasoning.—Yours, &c., F. H. NALDER.

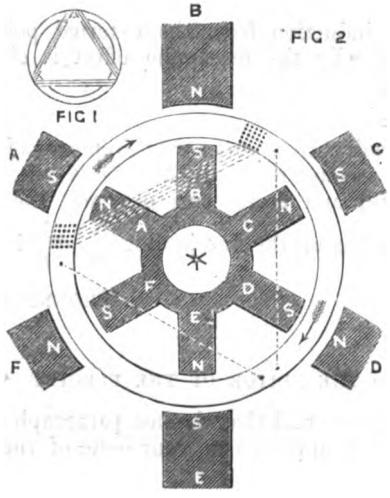
Isleworth, March 3rd, 1884.

## THEORY OF THE ELPHINSTONE-VINCENT DYNAMO.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: In accordance with the sensible suggestion of "One of the Crowd" I beg to offer an elementary explanation of the action of the Elphinstone-Vincent machine by the lines of force method.

The armature of this machine consists of a cylindrical drum, preferably of non-metallic material, upon which are laid a number of rectangular coils—usually, I believe, three in number, but there may be more. Fig. 1 will represent one end of a drum with three coils mounted upon it. This drum revolves in a magnetic field, produced by six external and six internal magnets, set with N and S poles alternating, and facing each other. In Fig. 2, which is a diagrammatic representation of this arrangement, the dotted lines indicate the position of the armature wire crossing the end of the drum, but the larger and more effective part of the coil is perpendicular to the plane of the paper.



Consider a coil when in the position shown in the figure. It is traversed by two separate sets of lines of force, but N lines due to magnets A A enter at the *inner* face of the coil, while N lines due to B B enter at its outer face. And as these pairs of poles are assumed to be of equal strength, and, moreover, the direction of the two sets of lines makes equal angles with the plane of the coil, they exactly neutralise each other. But when the armature begins to rotate in the direction of the arrow, the effective lines due to A A are diminished, while those of B B are increased in number; the effect of the angular displacement is also opposed to the former and in favour of the latter set of lines. A current is thus induced in a direction corresponding to the addition of N lines to the *outer* face of the coil. At the time when the plane of the coil has become normal to the lines B B, lines A A have been entirely cut out; and as the coil leaves this position lines C C begin to be added to the *inner* face of the coil, while lines B B are being diminished—therefore the direction of the current is now reversed. Thus, during one revolution, six successive currents in alternate directions will be generated in each coil of the armature. With the details of the commutator, &c., we are not now concerned.—Yours, &c., W. H. SNELL.

Liverpool, Feb. 26, 1884.

## PROFESSORS AYRTON AND PERRY'S FORMULÆ.

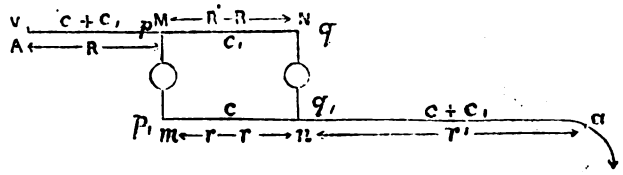
TO THE EDITOR OF THE ELECTRICIAN.

SIR: As your correspondent "E. E. A." does not appear to be able to understand these formulæ, perhaps the following proof may render them clearer to his mind.

Let the pole of the generator $a$ be connected to earth or be at zero potential.

Let the potential at A be V, at M be $p$, at $m = p$, at N $= q$, and at $n = q^1$.

So that if $x$ be the difference of potentials between M and $m$, $x = p - p$, and if $x_1$ be the same between N and $n$, $x_1 = q - q_1$.



We now have the following equations:—

$$V - p = R(c + c_1) \quad . \quad . \quad . \quad . \quad . \quad . \quad (1)$$

$$p_1 - q_1 = c(r - r_1) \quad . \quad . \quad . \quad . \quad . \quad . \quad (2)$$

$$q_1 = (c + c_1) r_1 \quad . \quad . \quad . \quad . \quad . \quad . \quad (3)$$

From (2) and (3) we obtain

$$p_1 = c(r - r_1) + (c + c_1) r_1 \quad . \quad . \quad (4)$$

Then adding (1) and (4) we have

$$V - p + p_1 = (c + c_1)(R + r_1) + c(r - r_1),$$

or

$$p - p_1 = V - (c + c_1)(R + r_1) - c(r - r_1)$$

$$\therefore x = V - (c + c_1)(R + r_1) - c(r - r_1).$$

In the same manner we can obtain $x_1$.—Yours, &c.,

E. C. RIMINGTON.

School Elect. Engineering, 12, Princes-street, Hanover-square.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: Having lately used my modifications of the above formulæ in some scores of calculations for a very large installation, and proved them correct, I was rather surprised by Mr. Wilkinson's last letter, as on substituting figures for letters in his formulæ the results agreed with those obtained from my own. In consequence I referred to my letter to you (February 9th), and find that I have therein inadvertently left out a pair of brackets in each formulæ, so that "as I understand the subject they should be"

$$x = V - [(c + c')(R + r) - c'(r - r')]$$

$$x' = V - [(c + c')(R + r) - c(R' - R)].$$

Thus, we are both agreed as to the misprint in the formulæ, as published in the *Journal of the Society of Telegraph Engineers*.

To show how easily a slip may be made in quoting formulæ, Mr. Wilkinson in quoting mine has substituted R' for R.

In thus closing the correspondence, so far as I am concerned, I would thank you for inserting my letters, and Mr. Wilkinson for his courtesy in assisting me.—Yours, &c., E. E. A.

## PROFESSOR BRACKETT'S ENERGY METER.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: In your issue of December 8th, 1883, you publish the description of an energy meter, in which the electric motor or dynamo under test is virtually made into its own dynamometer, the axis being so supported that the field magnets may be turned through a small angle. I wish to state that a paper on dynamometers, including this identical method, was read by me before the Physical Society of Bristol, at the University College of that city, about a month previous to the appearance of the description given in your paper from Professor Brackett. I mention this as any one reading a little book of mine on dynamometers (which will be out in a few days), in which the subject matter of the Bristol paper alluded

Digitized by Google

to is published, might possibly suppose that I had appropriated your description without due acknowledgment. The method spoken of I first used in 1881 while engaged in testing electromotors. Your kind insertion of the above will greatly oblige me.—Yours, &c. FREDERICK JOHN SMITH.

Taunton, February 25.

## QUESTION OF PATENTS.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: I have just had my attention called to a letter from a Mr. Teale, dated 7th February, and published in your issue of 23rd February.

If Mr. Teale had consulted the corporation before rushing into print, or had searched the patent register, he would have ascertained that the patent in question was duly assigned to the corporation on February 19th, 1881, and remains their property.

Mr. Schuckert's letter, quoted by Mr. Teale, shows that he has forgotten the facts, as the corporation holds personal communications from him, authorising his agent to conclude the sale, which was completed in due course.—Yours, &c.,

FRANK WYNNE, General Manager.

Anglo-American Brush Electric Light Corporation, Limited.

## OVERHEAD AND UNDERGROUND (?) TELEPHONE WIRES.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: Your correspondent who signs himself "Mos Legem Regit" appears to think that your readers would be interested in what he calls the "ventilation" of this question. He does not consider what a tedious discussion it would be to drag into your columns all the technical details that have to be considered before the policy of the telephone companies can be rightly understood. I do not want to be drawn into any controversy in support of the various companies, but my practical knowledge enables me to assure "Mos Legem Regit" and your readers that there is not so much inconsistency as he thinks in the proposal of the United Telephone Company to get an Act of Parliament to help them in their great public work. The "improper way" of fixing overhead wires is their being run diagonally in long spans from one side of the street to the other. The "proper way" that the United Company speak of would be to cross the streets at right angles, and suspend the wires parallel with the street, and directly over the roofs of the houses. A very little thought will show that the very irregular height of the houses would present difficulties and obstructions from the many householders that would claim to have a voice and even interest in the question. To cope with this obstruction nothing but an Act of Parliament would enable the company to continue to extend their business to meet the constant demands.

If the company get the power to suspend the wires over house tops without paying anything beyond damages to roofs, they do not expect there will be any necessity to lay wires underground. Is this not clear and reasonable?

As regards the objection to underground wires, it is well known that the effect of induction on neighbouring wires is vastly greater on wires close together, in pipes or cables underground, than it is on aerial wires. In some cases this annoyance is very much complained of even now, so what would it be if they were in bundles or "cables along the entire circuit?" But this is, as I have said, entering into uninteresting details. I could give a great many more. The result would prove that the question can be best thrashed out *pro* and *con.* before a parliamentary committee. If "custom rules the law," which is, I believe, the exact rendering of the words, *mos legem regit*, let the gentleman, whoever he is, show how custom is antagonistic to the policy or management of the United Telephone Company.—Yours, &c., TELEPHONIST.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: The dangers to life and property, and the disfigurement to our streets, caused by overhead telegraph, telephone, and other wires, have recently become subjects of general comment. The United Telephone Company, one of the private bodies interested in this matter, seeing the storm rising in the public mind, has decided to take action while there is still time, and is about to ask Parliament for very extended powers in a Bill to be introduced this Session.

The public have, in some respects, suffered so much from the exclusive rights given to the railway, gas, and water companies, that Parliament, in the Electric Lighting Act, was most careful to prevent the creation of a new monopoly. In defiance of this very recent precedent, the United Telephone Company asks for special legislation on its own behalf, with a laudable eye to its shareholders' interests. But the Telephone Company, after all, is but one of the licensees of the Post Office; and if the extraordinary powers asked for in their Bill are indeed necessary, which is much to be doubted, they should be given only to the representatives of the State, and not to a private corporation trading for profit.

Apart from the broad objection against fresh monopolies, the powers asked by the Bill are of the most objectionable character, and the old adage that "an Englishman's house is his castle," would cease to be true if they were granted. In the first place the Act would enable the company to enter at all hours, and as often as they pleased, and with as many men as they chose, any land or building, and to place and maintain any number of wires, cables, posts, and telephonic apparatus, of unlimited size, "in, upon, or over" any such land or building. They could enter any bank, any shop, any church, any court of law, any building whatever, including dwelling houses, as often as they chose, and place any number of telephone wires and instruments there. If I have a vacant piece of land adjoining my premises, with, say, a skylight admitting light to my cellars, they could fill it with tons of wires, tubes, and pipes, cover up the skylights, and block up the lights of my windows with posts and cables unlimited in number or size. They could bar the passage of carts or anything else through my yard by stretching wires across it. They could lay any number of wires, cables, or pipes, through my rooms, under my floors, or in or over my roof. They could fix their posts in or upon the Guildhall or Bow Church, lay their wires in a tradesman's shop, or in the treasure vaults of the Bank of England, and fix their "apparatus and appliances" in the sanctum of the Stock Exchange. In fact, the language of the Bill is quite wide enough to authorise them to set up a telephonic exchange in the nave of St Paul's Cathedral. For any *damage* caused they are to pay compensation; but in cases where they cause no damage they will have nothing to pay.

In the case of dwelling houses, the consent of the occupiers is certainly required to the erection of posts within a certain distance, but no consent is required to the placing of wires in or over any private property, even in cases like conservatories or glass-roofed sale rooms or shops, where suspended wires are a standing danger. In any case, the hanging of overhead wires would necessitate constant access even to private houses in the line of route, and the visits of telephone hangers, or of thieves who might represent themselves as coming from the company, at any time they pleased, would be by no means agreeable.

Secondly, coming to the powers which the company are to have for laying their wires in streets, they may place wires "over, along, or across any street," without any leave, in this respect extending the powers of the Telegraph Act of 1863; but they can only place wires under, or posts in, the streets with the consent of the local authorities, though Section 11 seems to deprive the authorities of the power of refusing their consent. There are certain "regulations" as to the height of wires carried along or across streets; in some cases they need not be more than fifteen feet from the surface, a height which it is obvious would effectually bar the passage of a fire-escape. Streets are to be broken up under the superintendence of the local authorities, and by Section 32 "any expenses incurred by any local authority in the exercise of any of the powers of this Act" are to be paid *out of the rates*, and not by the company, a provision which appears simply monstrous.

It seems highly unlikely that Parliament will grant such extended and tyrannical powers to a company, even if it were proved that a creation of a fresh monopoly were necessary in

Digitized by Google

the public interest; but the example of other towns, and of the Post Office in London, shows that *telephone wires can be perfectly well carried under the streets* without interfering with private property at all. It is true that the Act is not to apply to the whole country, but to the metropolis only. It is further true that the Bill is founded on the Telegraph Act of 1863, which contained a number of provisions for the government of the telegraph companies, whose undertakings are now vested in the Postmaster-General; but the proposed legislation is in many respects more favourable to the company, and framed with less regard for private and public rights. Besides this, at that time the rapid extension of overhead wires was not expected, any more than their further extension is now regarded. As a fact, that which commences with a single thin wire, in the course of a few months grows into perfect cobwebs of wires and cables, which threaten our lives and properties and deface the sky.

Lastly, it is provided by Section 26, that "the company shall be answerable for all accidents, damages, and injuries happening *through the act or default of the company, or of any person in their employment*, by reason or in consequence of any of the company's works." This section might be held to negative the company's responsibility for any injuries happening through any except the specific cause; so that if wires were blown down by a storm, or if a fire were communicated from house to house along the gutta-percha cables of the company (which may easily happen), or if lightning were conducted along them, no one whose person or property is injured could get any compensation from the company for the damage thus caused.

Some ten or fifteen years ago there was a serious snowstorm, when the flakes froze as they fell on overhead wires, thus adding immensely to their weight. The snowfall was followed by a high wind, which brought down a large portion of the comparatively few overhead wires then existing. A similar storm at this time, when overhead wires are so much more plentiful, would doubtless do more terrible injury to property, and possibly sacrifice much life. What compensation could be had from the telephone company under their Bill?

The chief concession that the telephone company offers in return for all its powers is, that power is given to the Board of Trade to order the removal of dangerous works, and to make rules for preventing them. It is, however, not provided that the company shall pay the cost necessitated by its own carelessness.

The solution of the whole of the difficulty arising out of the development of the new telephonic industry is the compulsory passing of the wires underground, and the avoiding of this course is simply with a view to economy.—Yours, &c.,

J. T. HUTCHINSON.

6, New-court, Lincoln's-inn.

## WATCHMEN'S DETECTORS.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: In reply to Mr. Walker Moseley's letter in your last issue, I may say that it was through seeing very great room for improvement in such watchmen's detectors as were supplied fourteen years ago that the idea suggested itself to me to simplify matters, and to render it impossible to make any record without leaving the room in which the clock is fixed, which can be done under Mr. Moseley's and similar systems.

With my scheme it is absolutely necessary that the man should not only visit each of the intermediate places, but also the terminal point on the circuit (where the battery is fixed) before any record can be made on the clock.

There is only one wire used, and for the short distance that two wires have to be led together special care is taken in fixing, and neither juvenile nor experienced electricians can get at them without detection.—Yours, &c.,

JNO. WM. FLETCHER,
Superintendent and Engineer.

London and North Western Railway,
Manchester, 27th February.

## THE INTRODUCTION OF THE ELECTRIC LIGHT INTO HOUSES.*

BY KILLINGWORTH HEDGES, ASSOC. M.I.C.E.

The author began with a reference to two papers on the electric light read before the institute by Mr. Slater in 1881 and 1882 respectively, and spoke of the great progress made since in the commercial application of the invention. To facilitate the lighting of streets and private houses the Electric Lighting Act of 1882 was passed, under which twenty-three applications for provisional orders were made in that year by local authorities, and 106 by companies formed for the extension of the system, which, however, the stringency of the regulations laid down by the Board of Trade had temporarily checked. Meanwhile a largely growing number of occupants of houses had set up the necessary plant for producing the light themselves. A description was then given of the plan for supplying electricity to private dwellings by means of batteries. The most effective system of the kind seemed to be that invented by Mr. Ross. The various modes of generating electricity were next rapidly reviewed. In town houses a gas motor was, as a rule, the best; in country houses all three sources of power—water, steam, gas—had been employed. Common coal gas could be dispensed with by using Dowson's gas, of which a description was given, and whose great advantages were set forth at length. The cost had been proved to be 50 per cent. less than that of the ordinary article at 3s. per 1,000 feet. The engine-house would contain the dynamos, which should be fixed on wood, to insulate them electrically from the ground. From the dynamos the current should be taken to a switch-board. If accumulators were used the current from these would join on to the same board. From this switch-board the mains went to the lamps, starting as a large cable, which branched away like the gas pipes until each incandescent lamp was reached. It was of the greatest importance in electric lighting that the current should always be uniform at all times in each individual part of the work, and independent of changes in other parts. The compound shunt machine for effecting this was then described, and it was shown that by means of it the regulation of the electric supply is more perfect than that of gas. The honours of this invention were claimed by several of our British electricians. A highly effective form of the machine was that designed by Messrs. Crompton and Kapp, who had greatly improved on the Bürgin dynamos, while Dr. Hopkinson had not only materially reduced the cost of Edison's, but had increased the commercial efficiency some 3 per cent. The actual efficiency of the improved Edison-Hopkinson dynamo was now 94 per cent., and its commercial efficiency 58 per cent. To enter, however, into a comparative description of the different systems possessing these advantages, and to discuss their relative merits, was beyond the author's scope, and he therefore proposed to describe some of the principal features of a supply of electricity, and to point out the precautions necessary to its safe introduction and the guarding against fire risks. In the first place, to understand what this electricity is, the author said, we must disabuse our minds of the notion of that "invisible subtle fluid" of which men still talked so nervously, but which we daily use with impunity for ringing bells and working telephones. The electricity used for lighting was doubtless far more dangerous if uncontrolled, but if properly installed it was made as harmless as the galvanic battery employed by the popular lecturer in his experiments. The light was nothing but electric energy in the form of white heat, and the only peril was that this heat might be developed where it was not wanted, and might so cause fire. The possible danger from this cause had already attracted much attention both in this country and abroad. A special fire risk committee appointed by the Society of Telegraph Engineers and of Electricians was formed in 1882, and a set of excellent rules were drawn up by it, which were adopted *mutatis mutandis* by some of the insurance companies, and also by the Board of Trade in its "model order." Neither these rules, however, nor the "Standard of Requirements" laid down by the New York Board of Underwriters could be said to embrace all the changing details of an electric light installation. Such details could only be arrived at after the electricity has been worked a sufficient length of time, and has been generally distributed like gas. With a view of eliciting further discussion on the subject, the author proposed to offer a few general remarks as a small addition to what had already been put forth by the fire risk committee. The first source of danger to property, he said, is in the mains and branch wires which conduct the electricity from the engine-house to the incandescent lamps, which were distributed over a house in much the same way as gas. If these conducting wires were of sufficient calibre, and made of a material uniform in its resistance, the current would not develop in its passage any dangerous heat. In arguing the question as to the proper sectional area of the conductor, the author remarked that the electromotive force had been compared to the difference of head of water necessary to cause a quantity of fluid to overcome the resistance of a pipe, whereas it was more like water soaking through sand, in that the whole of the cross-section of the wire interposes a resistance which in large conductors doubtless varies proportionally to the temperature of each section according to its distance from the outside radiating surface. As for the material of the wires, it was commercial copper, which was never absolutely pure, but could be got as high as 96 to 98. Now, since the wire's resistance depended on its purity, a short length of inferior wire might upset calculations based on the hypothesis that none but the purest wire is used. Thus not only might that inferior section become dangerously heated, but there would also be a waste of power. Copper was always used for electric lighting purposes, both because it can be got purer than any other available metal, and because next to silver it is the best conductor of electricity. Having examined the

* Abstract of a Paper read at the Institute of British Architects on Monday, February 18th, 1884.

Digitized by Google

proportion of the electric conductors to their work, the author went on to discuss the question as to the effect of a stream of electricity continually passing along them. He had found that if heating goes on largely, a change in the conductivity of impure metals may take place, but pure copper is apparently unchanged. A summary view of the evidence on which this conclusion rests was given. Passing thence to the subject of electrical connectors and joints, the author said special attention should be given to these, including not only all the joints where the branch wires lead off, but also the connections made with binding screws. Besides causing resistance in the circuit, bad contact between a wire and a terminal would engender heat; hence the area of the contact piece should be large enough. It was further shown how provision should be made in the case of a sliding connection for taking up the wear and firmly pressing the surfaces together. The joints used were most important factors in an electric light installation. For these joints solder alone should never be relied on. A joint must be made mechanically perfect, and considerable pressure used to unite the surfaces; the solder might be then applied to keep the whole air-tight. The next section of the paper showed how the danger arising from short circuits was to be met with. The term, it was remarked, meant that the current, instead of going a circuitous route, takes the shortest path, where, having no work to do, it causes fire. The three ways in which short cuts might be set up were pointed out as well as the measures to be adopted in such emergencies. The only preventive was a cut-out or safety fuse. The author referred to experiments of his own in order to ascertain the most suitable and reliable material. After trying numerous foils he obtained a special alloy of aluminium, whose resistance as compared with that of silver was about 45 per cent. Testing an installation was the next subject for consideration. To ensure this being properly carried out, a current capable of overcoming a high resistance should be sent through the whole of the wires; that from an ordinary battery was of little use. A portable hand apparatus was used for this purpose in America, which, on turning a handle, sends a current through every one of the wires, and shows any leakage by ringing a bell. The foregoing remarks, said the author, had been made with reference to incandescent lighting, but applied to arc lights also, which latter brought with them other fire risks of their own. The chief of these was the danger arising from pieces of incandescent carbon dropping, and more fires had occurred from this cause than from any other. Before quitting this subject he gave some interesting information as to how some of the fires caused by the electric light in America had happened. In one district, in which there were sixty-one mills, fifteen fires were due to some form of "short circuit," generally owing to the leakage of water or the washing of floors. All of them would have been prevented by proper insulation and reliable fusible safety plugs. Three fires were caused by cross arcs of one wire to another where uninsulated wires were fastened against conductors. In one instance the conductor was formed by dust settling upon uninsulated wires, and on a damp day it absorbed enough moisture to make a path for the formation of a cross arc, which started a fire. In a second case the wires were fastened to a damp beam, which was decayed and burnt nearly in two by a smouldering fire. In a third instance damp brick work in a tunnel became a sufficient conductor to set up an arc, which did no material damage, but injured the dynamo. These fires were not necessarily destructive, as they generally occurred during working hours, and so were soon discovered and dealt with. Electricity, though having no smell, like gas, to betray a leak, showed when it was escaping by the diminished brilliancy of the lights. In London Captain Shaw reported no fire as due to the electric light for 1882, and but one in 1883; this was due to the over-heating of the wires. In this country the installations had, as a rule, been in the hands of skilled persons. It was most necessary that in the eagerness and hurry to push forward the new light the work of wiring houses and fixing the lamps should not be left to bell-hangers and others destitute of the requisite knowledge of electricity. The best guarantee of safety in the use of the electric light was the employment of experienced men in the work of installation. In such hands it was far less dangerous than gas, which not only poisons the air we breathe, but ever lurks as a slumbering volcano ready at any moment to put forth a terrific power. When properly installed and managed electricity was by far the safest illuminant known. It was to be hoped the insurance offices would soon recognise the fact by reducing the premium on all buildings from which gas is excluded. The alleged comparative immunity of the electric light from accident was accordingly treated more in detail in a special section, which was followed by the author's closing remarks on the important subjects of wear and tear and working cost, all of them involving a good many technicalities in their discussion.—A discussion followed

## THE SOCIETY OF TELEGRAPH ENGINEERS.

The usual fortnightly meeting of this society was held on Thursday, the 28th ult., Professor Adams, president, in the chair. After the names of new candidates and fresh donations to the library had been announced, the president referred with regret to the death of Count du Moncel, an honoured and esteemed foreign member of the society. A balance-sheet for the past year was then submitted to the meeting in compliance with the law under which the society has recently been incorporated. As there had been no opportunity of examining this balance-sheet, however, no member rose to comment upon it; and it was only passed formally after the president had persuaded somebody to rise and second its adoption. It may be pointed out as evidence of the novelty of the whole proceeding that the balance-sheet in question, although well drawn up and printed, nowhere states to what it refers, and for all that can be seen to the contrary the accounts might be those of the Birmingham Caucus or the Society of Psychical Research.

Professor GEORGE FORBES, F.R.S.E., member, was then to have read a paper "On the Effects of Induction in Alternate Current Machines," but as he had forgotten to bring it with him, the meeting did not enjoy the privilege of listening to it.

Mr. B. W. M. MORDEY, associate, was accordingly requested to proceed with the reading of his paper, arranged to follow that of Professor Forbes. Mr. Mordey's paper was short, and was but imperfectly heard, chiefly owing to the speed at which he got through it. But it was recognised on all hands as a thoughtful paper, and one of extreme interest, relating to certain "Prejudicial Action in Dynamo Machines." Although Mr. Mordey's conclusions, some of them, were challenged by several members in the discussion which followed, he proved himself master of his subject, and it may be added master of debate as well; for, under a veil of modesty, real or assumed—it was impossible to say which—Mr. Mordey displayed a talent for irony greatly relished by the general body of members, who awarded the usual vote of thanks with unusual heartiness. Mr. Mordey's paper dealt with the several small causes of loss which are still unremedied in even the best of dynamos. If these losses could be reduced, though each was trifling in itself, and, some people might consider, unworthy of notice, the full powers of the machine might be very nearly realised. Foremost among the causes of loss were the so-called Foucault currents. In reality they were first noticed by Faraday, and all that Foucault had done was to observe their heating effects. Mr. Mordey therefore preferred to call them eddy currents. First, they caused the heating of the armature; secondly, they tended to demagnetise the ring. It was a matter of constant observation that their least effect was when the current was at its highest, the loss from the eddies being greatest when the dynamo was running slowly. To do away with the metallic armature had been suggested, but the gain would be more than counterbalanced by the loss by such an arrangement. Next there were the losses occasioned by a general rise of temperature in the conductors, copper wire in this relation suffering in conductivity, sometimes to the extent of 30 per cent.; hence it was desirable to work the dynamos in well ventilated places. After generally detailing the sources of loss known to be present in every dynamo yet invented, Mr. Mordey concluded a paper of which it is impossible to give more than the barest outline, by showing how serious these defects were in the aggregate, and how desirable it was, if possible, to remove them one by one, so as to get the ideal efficiency aimed at.

Mr. CROMPTON, while complimenting the author of the paper, regretted that it did not suggest remedies for the evils it had indicated. He was not himself sure that the eddy currents were the cause of the heating effects; they were, he conjectured, due to molecular movements; and if this were so, he thought our remedy might lie in using soft iron properly annealed, so that the molecular movements might be freed and cause as little friction as possible. He also deprecated the use of square drawn wire, which Mr. Mordey had mentioned as a possible mode of economising space, but which he, Mr. Crompton, thought objectionable on account of the difficulty of winding it free from kinks, and the danger of the insulator being cut by the sharp edges. Mr. Crompton warned intending purchasers against the mild steel which was now being sold as "charcoal iron." In reality true charcoal iron was now very difficult to get.

Mr. GORDON agreed with Mr. Crompton as to the cause of heating being molecular; and as to the employment of square wires he was under the impression that its self-induction was far greater than that of circular wire, and on that account was not to be preferred.

Professor FORBES called attention to the method of insulating wire by an electrolytic deposit invented by Wiedermann.

Mr. GISBERT KAPP, with reference to the size of armatures, mentioned that he had found that large armatures were slow to magnetise, and consequently were expensive working in the first instance, but were economical when the speed increased.

Professor AYRTON drew attention to the fluctuations in constant current machines. In the Brush machine these were no doubt caused by the projecting pieces of iron; and he described a method of testing that machine by means of a secondary circuit, which proved that the fluctuations were considerable. He also remarked upon the sparking observable when dynamos were employed for charging accumulators. Enlarging the field magnet would, he thought, lessen these effects, and produce greater uniformity. With regard to the employment of special kinds of iron, he had found that charcoal iron was not obtainable, foreign makers having taken to using coke.

Mr. MORDEY, in reply, dwelt chiefly on what had been objected to in his explanation of the heating effects. He pointed out that whereas there was no proof that molecular movement produced heat, there was ample evidence that eddy currents produced it. The essence of the dynamo machine was in the production of currents which we know actually do raise the temperature, which shorten the life of the machine, and which, indeed, might be made to melt it. If we revolve a penny before the poles of a magnet we know that heat is produced; we do not know that molecular movement under similar circumstances produces it. He therefore thought that present experience pointed to our counteracting the heat effects of the eddy currents rather than those of internal molecular friction. As regards Professor Ayrton's test in alleged proof of the fluctuations in the Brush current, he (Mr. Mordey) had made similar tests, only he had used an iron core with his secondary coil. Perhaps Professor Ayrton had not. The result was that he could discover no sign of those phenomena which Professor Ayrton had noticed; moreover, he had placed his tongue to the wires, a test which he deemed sufficiently trustworthy, and with the same negative result. The reference to sparking, he thought, supported his view, for the same dynamo that would run for a whole day and keep cool would become heated after a short spell of accumulator charging.

A hearty vote of thanks having been awarded to Mr. Mordey, Professor FORBES read some laboratory notes relating to telephones in lieu of his missing paper, and the proceedings closed.

## PILSEN, JOEL, AND GENERAL ELECTRIC LIGHT COMPANY (LIMITED).

An extraordinary general meeting of this Company was held at the Cannon-street Hotel on the 6th instant, to consider the subjoined resolutions :—

"1. That, notwithstanding anything contained in the Articles of Association, the directors be authorised, and are hereby directed, to carry out the following compromise and modification of the agreement with the vendors, the Union Electric Light and Power Company (Limited):—that is to say, that the directors shall take a surrender of the 11,530 fully paid-up £5 vendors' shares, which were allotted to the Union Electric Light and Power Company (Limited), in consideration of the purchase, and of such of the 470 like shares allotted to their nominees as can be obtained, and that the directors do pay in lieu and consideration thereof a sum not exceeding the amount of £1 3s. 4d. for each of such shares, and that, as hereby modified, the said agreement with the vendors be confirmed.

"That, if an order of the Court be obtained for confirming this resolution, the capital of the Company be reduced as follows :—(1) By cancelling the 12,000 fully paid-up vendors' shares as and when the same shall be surrendered pursuant to the foregoing resolution, or such of the said shares as shall be so surrendered. (2) By cancelling the sum of £1 per share on the 28,000 shares in the Company with £2 10s. called up thereon, and also on any fully paid-up vendors' shares which may not be so surrendered as aforesaid, as being capital which has been lost, or is unrepresented by available assets. (3) By reducing the amount liable to be called up on the 28,000 shares with £2 10s. called up thereon from the sum of £2 10s. per share to £1 10s. And that the Memorandum of Association of the Company be modified so as to carry into effect this resolution.

"3. That the directors be authorised to pay the costs and expenses, amounting to £55, incurred by the committee of shareholders up to the 5th February, 1884, when their scheme was submitted to the directors, as well as such further costs and expenses as have been, or if the scheme of the committee be adopted by the Company, may hereafter be incurred in reference to such scheme."

Sir Rawson W. Rawson, C.B., presided.

The SECRETARY (Mr. E. T. Gregory) having read the notice calling the meeting,

The CHAIRMAN said he assumed that the shareholders had received the two circulars addressed to them, one by the Board, and the other by the committee of shareholders who initiated the negotiations with the Union Company upon which the recommendations of the Board were founded. Therefore it did not seem probable that many remarks would be required from him to explain the objects of the Board, acting in conjunction with the committee. The object they had in view for some time past was to reduce the charges against the Company through the amount paid to the vendors ; and, secondly, to reduce the liabilities of the partly-paid shareholders to the fully-paid shareholders'. The Board believed that this had been very successfully attained by the scheme now proposed. The original bargain with the Union Company was to pay them £15,000 in money and £60,000 in shares, those shares being considered as fully paid up, so that the £60,000 had to be added to whatever amount the partly-paid shares contributed to the operations of the Company. At present they had contributed £2 10s. a share, which amounted to £70,000 ; therefore the combined charge to be met now was £130,000 of capital. By this scheme the Union Company had surrendered its £60,000 worth of shares for the sum of £14,000. Instead of their shares yielding to them, as anticipated, £5, they would yield only £1 3s. 4d., which he thought was an excellent arrangement for the shareholders in the General Company. He must point out that the Union Company had met them in a very fair and liberal spirit. The effect of that would be that the sum for which they had to provide dividends out of profits would be reduced from £130,000 to £84,000. They could imagine that in a business of this kind that was an important element in the future expectations of profit. He might here anticipate his remarks a little and point out that that £84,000 would be further reduced to £56,000 by cancelling £1 of the capital, as was proposed under the second resolution. Therefore, in future, all that the directors would have to do would be to provide for the expenses of the Company, and for the payment of a dividend upon this £56,000. That was one advantage gained by the resolution. Another one was of equal importance. There had been hanging over them—the partly-paid shareholders—the certainty that if the Company was not able to carry on its operations profitably and should be wound up, they would have to pay up in liquidation the whole of the balance on their £5 shares —that was £2 10s. a share—and that the fully paid shareholders would be entitled to their proportion of that amount before anything was returned to those who contributed it. The position was simply this—that every partly-paid shareholder would have to provide 50s. to the liquidator. The amount of that would be £70,000. Out of that three-sevenths would go at once to the Union Company, the holders of the fully-paid shares—or £30,000. The holders of fully-paid shares would be entitled to their share of the liquid assets of the Company whatever they might be, and to their share of the value of the patents, whatever they might prove to be. Now, instead of that £30,000 the Union Company, looking with fair and liberal eyes at the relative positions of the two classes, had consented to accept at the present moment £14,000, instead of that £30,000 and their expectations out of the assets of the Company. Therefore they, the partly-paid shareholders, found themselves in the position of having to provide a much smaller sum of profit in order to give a dividend to the shareholders, and they were relieved from this heavy liability of providing £30,000 to the Union shareholders. The committee had further proposed, and the Board had considered in the interests of the shareholders, in order to give a marketable value to their shares, that it would be desirable to cancel £1 on each share of the £28,000 at present paid up, and also to surrender another £1 of the liability under which they now laboured. As he had said, they were liable to be called on for £2 10s. on each of their shares. It was proposed that that liability should be reduced to £1 10s., and of that 10s. was to be applied to the payment of the Union Company to carry out this arrangement, They considered that the remaining £1 would be or might be necessary to ensure success and profitable results to the Company. If they had not a hope of those profitable results the money would not be spent, and therefore in abandoning the second £1 they simply said that there was no use in holding that liability over the heads of the shareholders, when they trusted either to succeed with a smaller sum, or, as honest men, to come before the shareholders and say, "We cannot succeed, and therefore let us close our business." Those were briefly the results of the proposed resolutions now submitted. The circular of the committee stated how the matter was initiated. The committee had been in friendly communication with both companies for a considerable time. Of course there were difficulties to be overcome, and although he thought they ought to be very grateful to the committee for what it had done in the interests of the Company, he for one had to thank the members of it for their exertions. Having a very large stake in the Company, and, consequently, being largely interested in its success, he had great pleasure in expressing his sentiments in that room, and he trusted that the resolutions, which had been before the shareholders now for a sufficient time to be understood, would meet with their assent. He concluded by formally moving the first resolution.

Mr. WHATELY seconded the resolution, and Mr. BLADON supported it, both gentlemen concurring in the view expressed by the chairman that it was the best possible arrangement that could be made in the interests of the Company.

Mr. JOHN TAYLOR said that as the holder of 250 shares, for which he had paid £5 each, he protested against the scheme before the meeting, as it was not an equitable one, and he would vote against the proposed resolutions. If they were carried he would oppose the order of the Court being obtained, and if need were he would carry the case to the House of Lords, so that before the scheme could be carried into effect much time would be lost, and a great deal of money spent in litigation. Having described the effect the scheme would have on the different classes of shareholders, he concluded by moving an amendment, adjourning the meeting, in order that the committee and vendors might meet the holders of the 470 fully-paid shares, and arrange a more equitable readjustment of the scheme in the interests of all concerned.

Mr. HUTTON seconded the amendment.

Mr. HOPKINS said that they must look upon the scheme from two points of view—that was to say, whether they were to go on with the business or to wind it up. And the proposed arrangement seemed to be much more favourable in the event of carrying on the business than in that of winding it up. It was very desirable to avoid litigation, and he would support the resolution, because it would be more in their interests to carry on the business, as he hoped would be the case, than to wind it up.

Mr. C. P. WHITELY thought the resolution should be passed unanimously. He did not see why those who had been ready enough to pay up their shares fully without being asked should object and try to influence the rest of the shareholders. If a gentleman chose to pay up money without being requested he must bear the burden of his action on his own shoulders.

The CHAIRMAN then put the amendment to the meeting, and it was lost, the mover and seconder being its only supporters.

The first resolution was then put and carried.

The CHAIRMAN next formally moved the second resolution, which was seconded by Mr. WHATELY and carried.

In answer to a shareholder, the CHAIRMAN said that they were never in a better position for making profits than now, and they had opened up a fair field of operations in Yorkshire and the north. With the present desire for electric lighting, especially amongst large manufacturers, in preference to gas, he could never more honestly say that he could look forward with confidence to making a profit than he could now, and the Board were prepared to exercise the strictest economy, and exert themselves as much as they could to obtain orders and promote the success of the Company. He concluded by moving the third resolution, which was seconded by Mr. BLADON, and agreed to.

Votes of thanks were subsequently passed to the chairman and directors, and also to the committee, for the zeal and energy they had exercised in the interests of the shareholders, and the proceedings terminated.

## THE EASTERN ELECTRIC LIGHT AND POWER COMPANY (LIMITED).

An extraordinary general meeting of the shareholders of this Company was held at the City Terminus Hotel, Cannon-street, on Wednesday last, under the presidency of Mr. L. Clark.

The SECRETARY (Mr. H. Cleland Heywood) having read the notice calling the meeting,

The CHAIRMAN said that a telegram had just been received from the chairman of the Company (Mr. Noel), saying that that gentleman was, through a severe illness, confined to his bed, so that the shareholders would not have the advantage of his presence on that occasion. At the same time this was, perhaps, of less importance than it would have been if matters had not taken the turn which they had within the last hour, and

Digitized by Google

as the result of which it might be thought advisable that the meeting should stand adjourned till a future occasion. They had received a telegram from India, from a gentleman whom they would all remember, Mr. Bull. He understood that Mr. Bull addressed the shareholders at the last meeting on the business of the Company, and stated that he was about to proceed to India on private business of his own, and that he would look into matters, and on his return report to them what his impressions were as to the position of the Company. Well, they had received a telegram within the last hour from that gentleman, through Mr. Ashburnham, the Company's representative there, advising the shareholders to suspend liquidation until his return, and asking for a remittance of £1,500, with which it was thought Mr. Ashburnham could pull through for two months, and complete the mortgage. Having this statement of Mr. Bull's, that so small a sum as that would enable them to live on for two months, and seeing that Mr. Noel was unable to be present, he thought, and the whole Board was of opinion, that it was desirable that the meeting should be adjourned for a month in order to give time to Mr. Bull to return to report what views he had formed, and possibly in the meantime to enable the directors to make some advantageous arrangement in the interests of the Company. He would therefore presently ask one of the members of the Board to move a motion to that effect. With respect to the £1,500 which had to be found, he should state that the Board had been very actively engaged during the last fortnight or three weeks in endeavouring to meet Mr. Ashburnham's wishes, and efforts had been made, with some degree of success, to obtain money in this country for the purpose of transmitting to him. But they could not succeed in raising the actual amount which Mr. Ashburnham thought he required—some £4,000 or £5,000. But the sum now demanded was so considerably reduced that he had every reason to believe that the Board would be able to accomplish the task of finding the necessary amount, and if this meeting were adjourned for a month they would be able to transmit the money to him to prevent their property from being sold by auction in India, and thus give them a chance possibly of turning the corner—at any rate of living a little longer. As regarded their position in India, he ought to state that this £1,500 would be entirely required for the purpose of getting rid of judgment debts which existed upon their property there, and therefore it seemed very important that this money should be sent out, and the Board would make every endeavour to obtain and transmit it. He would be happy to give any further explanation to shareholders who wished to ask questions. He ought to state that one portion of their property—the central portion—out there was paying its expenses, and he would further call to mind that their balance in hand when they last met was £370, so that the shareholders would see that to live so long they must have been managing very economically, and the delay of another month would not add materially to the embarrassments of the Company.

Mr. M'ARTHUR (director) said he had much pleasure in moving "That this meeting stand adjourned till Tuesday, the 8th of April next, at twelve o'clock, at Cannon-street Hotel." It was unnecessary for him to add anything to what the chairman had said. They had property in Bombay that would far more than cover their expenses, but certain parties were pressing them, and, as they had just heard, had obtained judgments, and were likely to take action against the Company. In that case, if the Company's property were sold by auction, it would be at a very great sacrifice. If time were allowed to realise on it, of course it would be much more valuable, and there might be more than sufficient to liquidate all expenses. Their great misfortune was that they had not a little more capital. If they had had a few thousand pounds more capital this difficulty would not have arisen, and they could have gone on with a fair prospect of success. But the fact was, that all electric lighting ventures had been so unsuccessful that the shareholders did not seem disposed to make further advances. Under these circumstances he thought the best thing they could do was to adjourn for a month, during which time the directors would use their very best efforts to succeed in sending out this small amount, which they hoped would bring about a better state of things, and perhaps enable them to avoid winding up altogether. At all events, as the chairman had said, if they were compelled to wind up at the end of the month, they would not be in any worse a position than they were in now.

Mr. JAMES PENDER seconded the motion, which was agreed to, and the shareholders separated.

## LEGAL.

### THE CENTRAL NEWS COMPANY (LIMITED)

*versus*

### THE EASTERN TELEGRAPH COMPANY, THE EXCHANGE TELEGRAPH COMPANY, SIR JAMES ANDERSON, AND ANOTHER.

This case came before Lord Coleridge and Mr. Justice Watkin Williams in the Queen's Bench Division of the High Court of Justice a few days since. We take the following report of the proceedings from *The Times*:—

This was a novel and a remarkable case, probably the first of the kind that has occurred, for it was an action by a news company against two telegraph companies and others for divulging news telegraphed to the plaintiff company (especially as to the victory of Tel-el-Kebir in Egypt) to other news companies, and so depriving the plaintiff company of the advantage of exclusive or prior intelligence. The action was commenced on the 5th of December, 1882, and the statement of claim, dated on the 23rd of that month, sets forth that the plaintiff company covenanted to carry on business as purveyors of news and news agents, and to supply telegrams containing intelligence or news to newspaper proprietors and others; that the Eastern Telegraph Company carry on business as carriers of telegrams, or messages for hire, by telegraph and otherwise, and that the Exchange Telegraph Company carry on the business of purveyors of news, agents, and newspaper correspondents, and suppliers of telegrams containing intelligence, or news, to newspaper proprietors, and that Sir J. Anderson was manager of the Eastern Telegraph Company (which, however, was denied, and he was said to be managing director), and the other defendant (a Mr. B. Smith) was chief officer at Alexandria of the Eastern Telegraph Company. Then it was stated that during the recent war in Egypt the plaintiff company had several correspondents or agents specially appointed, and in some cases sent out from England for the express purpose of obtaining for the plaintiff company the earliest and most reliable intelligence as to the incidents and course of the war, and any events occurring in Egypt, and of transmitting such intelligence in the most prompt and expeditious manner to the plaintiff company in England with a view to the circulation of the same among their customers. That at various times during the war the plaintiff company employed the Eastern Telegraph Company to carry by telegraph for the plaintiffs for inward telegrams or messages containing intelligence and news obtained for the plaintiffs by their agents or correspondents, upon the terms, among others, that the Eastern Telegraph Company would carefully carry the same, and would not publish or divulge the contents thereof, or allow any person in their employ to do so, and further that they would not allow any person carrying on any business similar to that of the plaintiffs to obtain any access to the messages or their contents. Then it was charged that the Eastern Telegraph Company did not carefully carry the messages so received by them, but published, or divulged, or allowed the contents thereof to be published and divulged to the Exchange Telegraph Company, or to their officers and servants, and negligently allowed them to obtain access to the contents, and that by reason of this the latter company, who then had no correspondents to collect news for transmission, improperly obtained the benefit of the plaintiffs' telegrams and messages, and among others a message containing the news of the victory at Tel-el-Kebir, which it was alleged the Eastern Telegraph Company had divulged to the Exchange Telegraph Company, so that the latter were able to, and did, supply it to their customers earlier than the plaintiffs could do to their own customers, thus forestalling the plaintiffs. And so the plaintiffs charged that the defendant companies wrongfully published the contents of telegrams of news sent during the war by the plaintiffs' agents and correspondents before the plaintiffs had made the contents public, and so the plaintiffs complained that they had been injured in their business, and to a great extent had lost the use and value of the telegrams and the labours of their correspondents, and they claimed £10,000 damages. The defendants—the Eastern Telegraph Company—in their statement of defence, denied these statements of the plaintiffs (except that the Eastern Telegraph Company were employed to convey telegrams for the plaintiff company), and they denied all the charges of divulging the contents or allowing them to be divulged. And the other company, the Exchange Telegraph Company, also on their part denied all the statements which concerned them; further, they alleged that if (as they denied) the contents of any of the plaintiffs' telegrams were divulged, they were so under these circumstances, that at the time referred to the English Government were engaged in military occupation in Egypt, and all telegrams sent from the seat of war were required by the English military authorities to be submitted to censors appointed for that purpose, and only telegrams passed by them were permitted to be sent, and they had power to alter or modify telegrams sent, and to send telegrams in such manner and to such persons as they thought fit, and so the defendants suggested that if the contents of any of the plaintiffs' telegrams were divulged to them, or were published by them, they were so divulged and published solely in consequence of the censors divulging them to the defendants, and dealing with them as they were authorised to do, and the defendants were not aware that any of the telegrams belonged to the plaintiffs, all which was denied by the plaintiffs. This was in March last year, and now an application was made on the part of the defendant companies for an order on the Electric News Telegraph Company to produce for inspection certain tapes, as they are called, or telegrams exhibited in clubs or reading rooms, in order that the dates of the messages or telegrams thus exhibited might be ascertained, so as to see if they would assist the defendant companies in the proof of their defence. The application was made upon an affidavit that the Electric News Telegraph Company (who, it will be observed, are not parties to the action) supply news to clubs and other subscribers by means of private telegraph wires, working printing instruments on the subscribers' premises, so that the news supplied by them is printed on continuous tapes by the subscribers' instruments, and that at the date of the telegrams mentioned the news supplied by the Electric News Telegraph Company relating to affairs in Egypt was to a large extent derived from the plaintiff company, and that the news contained in the telegrams was communicated by the plaintiffs (as they alleged) to the Electric News Company, and by them published to their subscribers very shortly after the receipt of the same by the plaintiffs, and that it is very material to the defence to show the exact times at which the contents of such telegrams were received by the Electric News Company, and by them transmitted to their subscribers, and that the latter will appear from the tapes of that date, copies of which it was believed are preserved by the Electric News Company, and the former would, it was said, appear from the books of the company, in which the time of receipt of such telegrams from the plaintiffs would be recorded, and that it was of great importance that the defendants should be able to inspect the tapes and books prior to the trial of the action for the purpose of obtaining the necessary evidence to be adduced at the trial, and it was also stated that it was probable that

Digitized by Google

by so doing the evidence that was necessary to be called would be greatly simplified and expense be saved; and, further, it was said that the inspection asked for could not be injurious to the Electric News Company, as there would be nothing of a private nature in the contents of the said telegrams or tapes. The application had been made at Judges' Chambers before Mr. Justice Mathew, who, however, was of opinion that he had no power to grant such inspection as against persons not parties to the action, and against that decision the defendants now appealed.

Mr. C. Russell, Q.C., and Mr. Moulton upon these materials now made the application to the Court on behalf of the defendants for an order to be allowed the inspection asked for. The order they asked for, they said, was to compel the Electric News Company to produce the tapes in their possession. The Electric News Company, they said, were certainly not parties to the action, but the new rules of 1883 were, they submitted, large enough to allow of such an order. Prior to those rules, under the Act of I William IV., witnesses might be examined before action (in cases of illness, extreme age, probable absence, &c.), and under the Common Law Procedure Act, 1854, Sections 46 and 47, on the hearing of any motion witnesses might be examined. Then the late rules—Order XXXVII., rules 5, 6, and 7, provided "that the Court may, in any cause where it appears necessary to justice, make an order for the examination of any person," and "the Court may in any cause, at any stage of the proceedings, order the attendance of any person for the purpose of producing any documents which the Court may think fit to be produced." Thus, therefore, it was clear that the Court had power to make such an order. Then it was clearly necessary for justice; the Electric News Company did not themselves receive telegrams from abroad, but the plaintiffs, the Central News Company, had correspondents all over the world, and received intelligence from them which they diffused, partly by means of the Electric News Company, which received news, and diffused it by means of telegrams to the various clubs, where they are exhibited on "tapes" pasted up as containing the latest news. The action was by the Central News against the Eastern Telegraph Company for alleged diverting of telegrams, by which, it was complained, the Central News had lost the advantage of priority in the news. One of the most important points in the case turned upon the hours at which the Central News themselves had published the telegrams, which, of course, would be dated. It would be most important to show at what times they had diffused the news by sending it to their various customers, and hence the application that the Electric News Company might be directed to produce for inspection their "tapes" of those days, these "tapes" containing, not only the news received, but also the hours at which they had been received. These "tapes" were, therefore, of the greatest importance, and there could be no doubt that at the trial witnesses from the Electric News would be subpœnaed to produce them. This is only an application that they shall be called upon before the trial to produce documents which they can be compelled to produce at the trial, and the production of which now can be no injury or inconvenience to them, while it would be a great convenience and advantage to the defendants. [Lord Coleridge: Is it not like calling upon a third party to produce his books and letters?] No, for these "tapes" have already been published, having been pasted up publicly in clubs or reading rooms, so that it is more like an order for inspection of the file of *The Times* at *The Times* office, on the ground that it is impossible to get at a file elsewhere. These "tapes" after being pasted up are destroyed. [Lord Coleridge: Is that so?] It is believed that it is so. [Lord Coleridge said he doubted it, and in a recent case which went to the Court of Appeal copies were produced in evidence.] The applicants were not aware of that, and at all events if they are documents already published, and perhaps obtainable otherwise, where is the objection to an order on the Electric News Company to produce these copies? The new rules are not now limited to the hearing of any motion; the power given is quite general. The Electric News Company's clerks and servants could be subpœnaed at the trial. [Lord Coleridge: They are not yet witnesses in the cause.] They may be. [Mr. Justice Watkin Williams: Your object is to ascertain beforehand whether it will be worth your while to call them as witnesses.] Be it so; that is not an improper object. [Mr. Justice Watkin Williams: Is it necessary to justice?] It is so, for it will save expense, and conduce to the speedy discovery of the truth. [Lord Coleridge: It may, no doubt, be very convenient to your clients, but does that justify an order on parties who are strangers to the cause to produce their books and papers?] It is conceived that it does; it is not doubted that it would be an advantage to the defendants; it is within the rules, and where is the objection to it? [Lord Coleridge: It will introduce a new principle—a principle inquisitorial in its character.] The documents are in no sense private; they have already been publicly exhibited. They are not at all like private books or letters. It is merely an application to be allowed to see before trial what can be called for at the trial.

Mr. Pyke appeared for other defendants; Mr. C. Dodd for the plaintiffs.

Lord Coleridge said the present rules combined the previous ones, which did not admit of such an application as this, and certainly did not contain the limitation or restriction which attached to the former enactments; and he did not quite see on what ground his brother Mathew had held that there was no power to make such an order, though he was not prepared to say that he was wrong. But, without deciding whether or not the Court had such a power, he was clearly of opinion that no case was made for its exercise. It was obvious that if the rule was as had been asserted it was a rule capable of being applied in furtherance of the most oppressive and inquisitorial proceedings; and if it were, indeed, matter of right to call for such an order, it was not in human nature that it would not be abused. Therefore, it was a power of which, if it existed, the exercise should be guarded with the most watchful jealousy. Without saying that the Court would not, under proper circumstances, make such an order, and that there might not be cases in which the power might be justly exercised, it would be, in his judgment, extremely oppressive to hold that whenever it might tend to the convenience of one of the parties to an action, or might conduce to the saving of expense, a person not a party to the cause, nor yet a witness, having nothing to do with the cause, should be called upon to produce his most private and secret papers. It was only said in this case that the inspection of these papers might show something material; but it was possible that it might show nothing at all material. It was possible that any private letter received by a stranger to the cause might contain something material to the cause; but what reason would that be for its production? There ought to be a very strong case to induce the Court to make such an order, and no such case was made here. There were, perhaps, twenty cases in London to which recourse might be had for such papers without the intervention of the Court. The power invoked was one which ought to be exercised most carefully; and he was of opinion that no sufficient case had been made for the production of these documents, and that, therefore, the application must be refused.

Mr. Justice Watkin Williams concurred. The application was for an order on a stranger to the action to produce documents which were his property, and in which the applicants had no interest. No doubt, the rule was extremely wide in its terms; he could not say that grammatically they were not sufficient to confer such a power (though, perhaps, it might be doubted whether, if so, it would not be ultra vires, and beyond the power of the judges to make); but this it was not necessary to determine, and it was enough to say that, assuming such a power to exist, it was one which ought to be exercised with extreme caution, or otherwise it would be oppressive; and in this case he thought no case was made for its exercise, and that, therefore, the application must be refused, and the appeal dismissed.

## NOTES.

CABLE INTERRUPTED.—The cable between St. Vincent and Pernambuco is interrupted.

TELEGRAMS FOR THE CANARY ISLANDS.—The cable between Cadiz and the Canary Islands is interrupted.

THE MAXIM-WESTON ELECTRIC COMPANY.—This company has removed its works from Bankside to Holywell-lane, Great Eastern-street, E.C.

HARROGATE ELECTRO HYDROPATHIC COMPANY.—On the 17th inst. Mr. Justice Chitty will, at the Royal Courts of Justice, appoint an official liquidator of this company.

CABLES REPAIRED.—The cable between Lima and Mollendo, and that between Grenada and Trinidad is repaired. That between Antigua and Guadeloupe, however, is still interrupted, as is that between Guadeloupe and Dominica.

APPOINTMENT.—We learn that Mr. F. W. Ford, who has for more than five years acted as assistant to the Secretary to the Society of Telegraph Engineers and Electricians, is now on the staff of the Institution of Mechanical Engineers.

CANADIAN TELEGRAPHS.—A Canadian Blue Book just issued says that Canadian tariffs are probably the cheapest in the world, and will still compare favourably with the reduced rate of sixpence shortly (?) to take effect in England.

UNDERGROUND WIRES IN MELBOURNE.—The first underground telegraph cable laid in Victoria has been put down at Spencer-street Station by Mr. K. L. Murray, electrical engineer of the railway department. There are two cables, each containing a number of wires.

THE INDO-PERSIAN TELEGRAPH.—News from India says that the settlement of pending questions connected with the protection of the Indo-Persian telegraph has been arranged. The Khan of Khelat has accepted the responsibility of protecting the line and the *employés*.

METROPOLITAN BRUSH ELECTRIC LIGHT COMPANY.—Mr. Justice Kay has made an order, on the petition of Mr. A. Peebles, that the voluntary winding up of this company shall be continued under the supervision of the Court. The company, it may be added, made no objection to the order.

THE SOUDAN.—A telegram from Cairo, dated March 11, stated that the telegraph wire was broken to the south of Dongola. Later news says that telegraphic communication has been restored with Khartoum. The line had been cut by rebels, who, however, offered no opposition to its being mended.

BRAZILIAN SUBMARINE TELEGRAPH COMPANY.—The directors of this company have declared an interim dividend of 3s. per share, or 6 per cent. per annum, for the quarter ended 31st December last, and payable on the 25th inst. The transfer books will be closed from the 18th to the 24th inst., both inclusive.

EARTHQUAKE IN NEW ZEALAND.—The *Colonies and India* says that a very smart shock of earthquake has been felt at Wanganui. It lasted 15 seconds, the direction being apparently from east to west. No damage is reported. This would probably be about two months ago, though our contemporary does not give the date.

TELEGRAPHIC COMMUNICATION WITH HOLLAND. — Mr. Fawcett having received a petition from commercial gentlemen in the City, praying for an improvement in the telegraphic communication with Holland the Postmaster-General has replied that immediate steps are now being taken to restore the communication in a permanent and satisfactory manner.

THE GRAMME PATENT.—The 2nd of April, at 10:30 a.m., has been fixed by the Judicial Committee of Her Majesty's Privy Council for hearing the petition of the British Electric Light Company for a prolongation of the term of the letters patent granted to Zenobe Théophile Gramme and Eardley Louis Charles D'Ivernois, of Paris, dated the 9th of June, 1870, No. 1668.

THE EDISON-SWAN COMPANY.—Mr. Albright, who has been connected with the Swan Company almost since its beginning, and who on the amalgamation of the Edison and Swan Companies took a position as head of the ship lighting, has now been appointed resident engineer of the Edison-Swan United Company, in charge of all the work. We congratulate Mr. Albright on his appointment.

ACCIDENTS BY LIGHTNING.—Following on the suggestion of the International Conference of Electricians held in Paris, in 1882, the French Minister of Posts and Telegraphs organised a system of observations throughout that country relating to thunderstorms and accidents by lightning. The series began in January 1883, and the results of the first half year's observations have just been communicated to the Academy of Sciences.

INDIAN AND ORIENTAL ELECTRICAL STORAGE COMPANY.—Notice is given in the *Gazette* that a petition for confirming a resolution reducing the capital of the above company from £400,000 to £280,000, was, on the 26th of February, presented to Her Majesty's High Court of Justice, and is now pending before the Vice-Chancellor Bacon, and that the list of creditors of the company is to be made out as for the 12th of April, 1884.

OVERHEAD WIRES.—A meeting of representatives of the Post Office, the Local Government Board, and the Board of Trade, and of certain telephone companies, took place on Wednesday at the Post Office. It is understood that an announcement was made that the Government would oppose all private legislation on the subject of overhead telegraph and telephone wires, and would not themselves introduce into Parliament any general measure until the termination of the litigation now pending.

ELECTRIC LIGHTING ON A MAN-OF-WAR.—The lighting of H.M.S. "Colossus" has been entrusted by the Admiralty to the Anglo-American Brush Electric Light Corporation, whose engineers and electricians are to have entire control of the whole work. Brush incandescent lamps will be used, and the current will be supplied by three "Victoria" dynamos, as specially constructed by the corporation for incandescent lighting. We wish the Anglo-American Corporation every success with the contract.

DOMESTIC LIGHTING.—Mr. A. S. Grove, of Lower Sydenham, writes as follows:—"I have used 20 candle-power 42 volt Swan and Woodhouse and Rawson lamps, in conjunction with bichromate batteries, with Trouvé's solution, for eighteen months, lighting up on an average twice a week, sometimes much oftener. Trouvé's solution is much more convenient, cleanly, and just as powerful as Bunsen's (I used Bunsen's at first, and gave it up), and although the solution only lasts 5½ hours, yet one seldom wants the light for more than that at once."

THE TELEPHONE IN HOLLAND.—The Netherlands Bell Telephone Company, formed in December, 1880, now has a total number of subscribers amounting to 2,053. In Amster-

Digitized by Google

dam there are 1,070 subscribers to the company's system, in Arnheim 121, in The Hague 156, in Rotterdam 494, in Groningen 64, in Utrecht 76, in Haarlem 58, and in Zaandam 19. Several of these exchanges have only been established during the last fifteen months. The number of calls per month in Amsterdam, where an exchange was established in July, 1881, now amounts to 101,500.

ELECTRIC LIGHT IN THE WAREHOUSE.—Messrs. J. Simonsen and Company, of 8, Milk-street, are having their new premises at 5, Dowgate-hill, Cannon-street, fitted with the electric light. The work is being carried out by Messrs. Crompton and Company. The lower rooms are being fitted first with 36 Swan lamps, but ultimately more lamps will be used, as the upper rooms are ready. The dynamo will be capable of supplying current for 86 lamps. It is a compound wound Crompton-Bürgin machine, and will be driven by a Crossley-Otto gas engine of 6 horse-power.

ELECTRIC LIGHTING AT LEEDS.—The *Leeds Mercury* says that at a recent meeting of the Electric Lighting Committee of the Town Council, the tender of Messrs. Paterson and Cooper, electricians, London, for the lighting of part of the new municipal offices by electricity was finally accepted. The tender is for lighting the Free Library section of the buildings with 284 incandescent Swan lamps of 20 candle-power each. There will be 74 Swan lamps in the general reading room, 70 in the lending library, and 140 in the reference library. We leave the responsibility of this statement with our contemporary.

THE CONDUCTIVITY OF SALINE SOLUTIONS.—M. Jamin has presented a further note to the French Academy of Sciences relating to M. Bouty's observations on the conductivity of saline solutions, mention of which was recently made in these columns. The result of experiments made by M. Jamin between 2° and 44° centigrade is that (1) the electrical conductivity of a neutral salt in very extended solution increases proportionally to the increase in temperature, according to the formula $c_t = c_0(1 + kt)$. (2) The coefficient $k$ is the same for all neutral salts. The mean value of this coefficient is—$k = \cdot 033543$.

EXTENDING THE TELEGRAPH IN SCOTLAND.—In the House of Commons on Monday last, Mr. Fawcett said, in answer to Mr. Cameron, that some correspondence had taken place between the Post Office and the Fishery Board in Scotland with reference to the extension of the telegraph to Barra and other remote districts of Scotland, but the extension could not be carried out unless those interested were prepared to guarantee the department against loss. The terms of the guarantee had been sent to those interested, but no reply had yet been received, and he was consequently not prepared to say whether any such extension would be carried out.

THE EASTERN TELEGRAPH COMPANY AND THE SOUDAN.—Speaking of the generous act of the Eastern Telegraph Company in allowing wounded officers and men to telegraph home free of cost, which we noticed in our last issue, the *Standard* Cairo correspondent says:—"This graceful act affords me an opportunity for noticing the unvarying efforts made by the representatives of the company to meet the private and public requirements, although these are so greatly in excess of the ordinary telegraphic traffic. Their work has been arduous and heavy, and their services have been so great and so ungrudgingly rendered as to deserve general recognition and gratitude."

ELECTRIC LIGHTING IN OUR HOMES.—Mr. Preece has told us that progress is being made, and we, on our part, try to obtain information about installations and put upon record work done. It is with pleasure, then, that we find Mr. R. W. Webster, Q.C., having the electric light installed in his house—Hornton Lodge, Kensington. The wiring was partially done by the Edison Company, and has been completed by Messrs. Crompton and Company. A Crossley gas engine of 3½ horse-power will be used to drive a shunt-wound Crompton-Bürgin dynamo to give current for 35 Swan lamps. Dr. Frankland's accumulators, made by Messrs. Crompton and Company, according to the specification of Dr. Frankland, are to be used in this installation.

FAIRY LIGHTS.—At a recital of "Iolanthe," given at the Park Hall, Sydenham, a few days since by children, under the direction of Mr. C. H. Cellier, the fairies and their queen wore incandescent "star" lamps. The current was supplied by a small accumulator, weighing 1½lb., concealed under the trimmings at the back of the dresses, and secured by an elastic band, fastened round the waist. Flexible wires with a switch of the same colour as the dresses were led up to the head. The lamps were fixed on a comb in front of a small reflector, and had a very pretty effect. The batteries and lamps were made by Messrs. Woodhouse and Rawson, and were lent for the occasion by Mr. A. S. Grove, of Lower Sydenham, who arranged the details. The batteries gave a current which lasted for 45 minutes.

ELECTRIC LIGHTING FOR DANCING.—On the evenings of February 20th and 22nd two dances were given by Mr. C. H. Devey, at Lucan Lodge, Clapham Park. The whole of the reception and dancing rooms were lighted up by 40 10 candle-power incandescent lamps, supplied with current by 30 Faure-Sellon-Volckmar accumulators, the same cells being used for both nights. Miss Devey wore a small fairy lamp with star fixed on a comb in her hair. Arrangements were made by using two batteries for replenishing as often as necessary the battery, which was made by Messrs. Woodhouse and Rawson. In this manner she was enabled to have it alight all through the evening on both nights. All the wiring and fitting up was done by Mr. A. C. Devey, late of the School of Electrical Engineering, Hanover-square, and the batteries, lamps, &c., were supplied by Messrs. Woodhouse and Rawson, 7, Queen Victoria street. As usual when electric lighting is employed, although the rooms were very crowded on both nights, there was no oppressive heat.

SEARCH LIGHTS FOR THE NAVY.—In the House of Commons on Monday last, Sir H. Wolff again brought up the question of the electric light for gunboats and other vessels of the navy, with particular reference to the present operations in the Soudan and on the Red Sea coast, and compared the French Navy and our own in this respect, to the disadvantage of the latter. Whereupon Mr. Campbell-Bannerman stated that it was not usual, and he did not think it ever would be the custom, to fit the electric light to the smaller class of gunboats, and in order to remove any idea that the lack of the electric light was a loss to our forces on the Red Sea, there was, at all events, an opinion entertained by a great many competent authorities that the electric light for purposes of war was not of great value. We would point out that as "doctors disagree," so "competent authorities" often prove to be but mortal, and the word competent, as applied to their authority, frequently turns out to be but a relative term. The search lights used on the occasion of the bombardment of Alexandria, and subsequently at Ramleh, at all events, proved to be of great utility.

THE JABLOCHKOFF COMPANY.—The following notice has appeared in the *Gazette*:—"By an order made by Mr.

Digitized by Google

Justice Pearson, dated the 23rd day of February, 1884, on the petition of David Hulett, it was ordered that the voluntary winding up of the Jablochkoff Electric Light and Power Company (Limited), be continued, but subject to the supervision of the Court; and any of the proceedings under the said voluntary winding up might be adopted as the judge should think fit; and it was ordered that William Augustine Spain, the provisional official liquidator of the said company, appointed by an order dated 1st February, 1884, be discharged; and it was further ordered that the said William Augustine Spain should retain any moneys which he had received as such provisional official liquidator, and account for the same as liquidator of the said company; and it was further ordered that the costs of the petitioner, and of the said company, and of Rivers Everett, a contributory, should be taxed by the taxing master, and paid out of the assets of the said company; and the creditors, contributories, and liquidator of the said company, and all other parties interested, are to be at liberty to apply to the judge at chambers as there may be occasion."

Ship Lighting.—The ss. "Cahors," built by Messrs. Key and Sons, of Kirkcaldy, for the Australian Steam Navigation Company, has been lighted throughout by the electric light, the contract having been entrusted to Messrs. Woodhouse and Rawson, of 11, Queen Victoria-street, E.C. The saloon in this ship is particularly adapted for the electric light, no expense having been spared in fitting it up. The vessel is considered to be one of the finest and handsomest boats ever launched on the east coast of Scotland. The ceiling of the saloon is handsomely painted with figures of hunting scenes by a first-rate artist, and the fittings are all in satin wood, with parquet flooring throughout. The installation consists of 133 Woodhouse and Rawson incandescent lamps of 10, 20, and 50 candle-power, the current being supplied from a Bürgin compound shunt dynamo. The deck, fore and aft, is illuminated at night time by two groups, each consisting of three 50 candle-power lamps, enclosed in clear glass globes, with a large reflector above, with special arrangement for entrance of cable. These can be raised and lowered as required, and will be used for dropping into the hold of the vessel when loading or unloading. We may mention that the installation has given great satisfaction to the builders and owners, and that this is the second ship that Messrs. Woodhouse and Rawson have lighted for the same firm. Messrs. Woodhouse and Rawson's safety junctions and ship's branch lead switches are used throughout, so that all the lights are controlled from the engine room and from the various quarters. Each pair of berths is lighted by one lamp in the ceiling between the two, the switch being in the passage outside.

A Telegraph Clerk's Responsibility.—Damages have just been obtained by a merchant in Frankfort against a telegraph *employé*, for negligence in sending a message. The facts are as follow:—The merchant despatched a telegram to his printers, telling them to stop printing certain circulars, and that verbal explanations would follow, signing the message with his name. The message was correctly sent, with the exception that the signature was omitted by the operator. In consequence of this the printer was in doubt as to who had sent the telegram, and having a number of circulars in hand for different persons, had to make a guess, which turned out to be wrong. The merchant's circulars were gone on with, and some one else's stopped. In due time this was found out, and the merchant applied to the telegraph office for the name of the operator in fault, which information was afforded him. After vainly endeavouring to get the operator to pay a portion of the expenses incurred, owing to his error, the merchant sued him in court. The operator based his defence on the fact that the administration had a clause in their regulations stating that they declined all responsibility for alterations or delays to telegrams, and this, he argued, applied to their operators as well. He contended further, that had the merchant paid an extra charge, he would, under these regulations, have been entitled to damages, but not having done so, he was not. The Court, however, held that this defence was invalid, and that the fact that the administration was not responsible did not take the responsibility off the shoulders of its *employés*, and that the latter were liable for any errors committed by them. The operator in question was therefore condemned to pay the merchant's expenses.

The Daniell Battery.—M. Emile Regnier, of Paris, has been carrying out a series of experiments with the Daniell battery. He tried the following solutions:—1. In the copper compartment, a saturated solution of sulphate of copper; 2. A solution of sulphate of copper, acidulated by the addition of $\frac{1}{20}$ (by volume) of monohydrated sulphuric acid. In the zinc compartment he used—1. A solution of sulphate of zinc, 500 parts of the salt (by weight) to 1,000 of water; 2. A solution of sulphate of zinc, acidulated by $\frac{1}{20}$ of sulphuric acid; 3. A solution of sea salt, 200 parts of salt (by weight) to 1,000 of water; 4. A solution of sea salt acidulated by $\frac{1}{20}$ of sulphuric acid; and 5. Water acidulated by $\frac{1}{20}$ (by volume) of sulphuric acid. With these solutions he obtained the following results:—

| Liquids. | | Electromotive Force. Amalgam. Zinc. | Ordin. Zinc. |
|---|---|---|---|
| Copper compartment. | Zinc compartment. | Volt. | Volt. |
| Solution of sulphate of copper, saturated... | Solution of sulphate of zinc ..... | ... 1·079 | ... 1·068 |
| Ditto..... | Ditto, acidulated ... | ... 1.105 | ... 1·06 |
| Ditto, acidulated..... | Ditto ..... | ... 1·03 | ... 1·25 |
| Ditto, acidulated..... | Ditto, acidulated ... | ... 1·066 | ... 1·03 |
| Ditto, saturated ..... | Sea salt ..... | ... 1·145 | ... 1·14 |
| Ditto, acidulated..... | Ditto ..... | ... 1·115 | ... 1·09 |
| Ditto, acidulated..... | Ditto, acidulated ... | ... 1·125 | ... 1·09 |
| Ditto, saturated ..... | Water, acidulated with sulphuric acid | ... 1·134 | ... 1·05 |
| Ditto, acidulated..... | Ditto ..... | ... 1·119 | ... 1·027 |

The measurements were made soon after mounting the cells. Several of M. Regnier's figures do not agree with those of Poggendorf, Joule, Regnault, and Wiedemann. This disagreement he thinks arises partly from errors in the choice of coefficients adopted for the reduction to volts of the results obtained by these physicists. M. Regnier's experiments are given in our contemporary, *L'Electricien*.

American Scientists on the Red Sunsets.—At a meeting of the New York Academy of Sciences on the evening of Feb. 11, Professor John K. Rees, of Columbia College, read a paper entitled "Theories in Regard to the Causes of the Recent Red Skies." Professor Rees pointed out several of the recorded phenomena before proceeding to discuss the theories as to their cause. There were three theories, he remarked, which were worthy of consideration: That ascribing the glow to the presence of aqueous vapor, that attributing it to cosmic dust, and that finally which traced it to volcanic dust. He considered these briefly in that order, dismissing the aqueous vapor theory as accounting only for the different coloured suns. The spectroscopic investigation, which gave weak rain lines and a well defined dry air band, also prevented the acceptance of this theory. The cosmic dust theory was next reviewed, but also met with little favour, as the analysis of the particles which had been collected from snow and rain water proved them to resemble volcanic rather than meteoric matter. Professor Rees was inclined to believe that the theory which attributed the usual sunsets to the presence of volcanic dust thrown out

Digitized by Google

during the Java earthquake presented less difficulties than either of the others. He stated that this was probably the greatest volcanic eruption on record. Thousands of tons of volcanic dust must have been thrown into the air. In rebutting the objection that the speedy settling of such dust would prevent the persistence of the phenomena, he brought forward Professor Crook's theory that the minute particles were negatively electrified, and were therefore not only repelled by the earth but also repelled each other, and thus might be kept in the air for an indefinite length of time. Finally, Professor Rees referred to one or two other theories, electrical and scriptural, which had been promulgated, and also to that which held that the earth is surrounded by a meteoric ring above the equator. This last he considered untenable, as the glows were as perceptible south of the equator as north of it. Professor Trowbridge then made a few remarks, in the course of which he cordially endorsed Professor Rees's views, and suggested that the upward currents of the air might have much to do with keeping the particles suspended in the atmosphere, and thus account for the persistence of the phenomena. Professor Newberry added the results of his observations, which were strongly confirmatory of the volcanic dust theory.—*Scientific American.*

An Electrical Fly-catcher.—A correspondent in the service of a cable company abroad sends us the following account of a somewhat original experiment, which may amuse those whom it does not interest:—"One day recently, having a little spare time whilst on duty in a cable-hut, which is generally infested with flies, an idea suddenly struck me that perhaps an electrical fly-catcher would be of some service in abating the nuisance, and, moreover, would be in harmony with the surroundings. Accordingly I constructed the following: A strip of sheet-lead about 4in. long by 1in. wide was connected to one pole of a 36-cell Leclanché battery, a bright copper-wire was then bent so as to surround the lead-plate at a distance of about 1-10th of an inch and connected to the other pole of the battery; to make the experiment more complete a key with which to make and break contact and a small galvanometer were introduced into the circuit. A small quantity of honey was placed on the lead-plate to attract the flies, and both plate and wire were wetted with mineral water in order that the flies should make good contact. The electrical fly destroyer being complete, I watched for results. However, like Mr. Stroh, in a microphonic experiment which he described before the Society of Telegraph Engineers last year, I was disappointed. Mr. Stroh did not *see* his watch tick; I did not see my flies killed. What I expected to see was that, directly, in their eagerness to approach the honey, they touched the lead plate with their fore feet, their hind ones being still on the copper wire, they would fall down dead 'in their tracks,' and without a struggle, and that all I should have to do would be to sweep away the dead bodies to make room for fresh victims. However, what they actually did was very different. Some just sniffed at the wire, and evidently suspecting something wrong, flew off, not giving the apparatus a fair trial; others fell into the trap, and clambered over the wire, but directly they touched the lead plate, instead of dropping down dead, they merely gave a kick and a jump and also flew off, the deflection of the galvanometer needle being barely perceptible. All my dreams of a 'Patent Electrical Fly Destroyer,' with a speedy and colossal fortune to follow, were thus rudely dispelled. However, before disconnecting the apparatus, I resolved to try a few experiments, and so caught a few flies by stunning them (it requires some art to stun a fly and not to kill it), and then placed them carefully on the instrument; the only effect was to make them kick and buzz. I tried making and breaking the circuit rapidly, which (with several flies in circuit) produced more kicking and spluttering, and somewhat increased the galvanometer deflection. And after all it seemed to do them good, as after being removed from the apparatus for a short time they recovered, crawled about, and finally flew off, sadder if not wiser flies. Regarded as a fly-catcher the apparatus was a failure, but if it should induce any electrician to measure the electrical resistance of a fly it may yet result in some slight contribution to our scientific knowledge."

Rating Telegraph Wires.—The case of the Compagnie Francaise du Télégraphe de Paris à New York *v.* Penzance Union came before the Lord Chief Justice and Mr. Justice Cave, in the Queen's Bench Division of the Supreme Court, on the 9th inst. It was a special case stated for the opinion of the Court, and raised a question as to the liability of the appellants, the telegraph company, to be rated for the relief of the poor. The appellants owned certain submarine telegraph cables between France and America, and also worked certain submarine cables between France and a point on the Cornish coast, near Land's End, and carried on the business of a telegraph company in connection therewith. In order to carry on their business the appellants, on the 14th April, 1880, entered into an agreement with certain submarine telegraph companies who were possessed of concessions for the laying of submarine telegraph cables between the point at Land's End and a point on the French coast, and also with her Majesty's Postmaster-General. Under an agreement with the Postmaster-General, dated Jan. 25, 1881, appellants were to have the use of two telegraph wires which are the property of the Postmaster-General, these wires being supported on poles in the ordinary way, and extending from Penzance to the landing place of the telegraph cable at Land's End. The wires passed through the parish of St. Burgan, in the Penzance Union, and the Assessment Committee of that union included in their valuation the appellants as persons liable to be rated for the relief of the poor in respect of the alleged occupation of such wires. The appellants appealed from that assessment to the Quarter Sessions of Cornwall, but it was agreed between the parties that the appeal should be respited until the opinion of the Queen's Bench Division had been obtained. Under the agreement in question the Postmaster-General agreed to keep and maintain for the exclusive use of the appellants two special wires from Land's End to Penzance, from Penzance to the city of London, and from Penzance to Liverpool, and from the city of London to Liverpool. But the Postmaster-General reserved to himself, as regarded Land's End and Penzance, the right of saying from day to day which of the two wires appellants should use. The question now raised before the Court was whether this exclusive use of these two wires was a beneficial occupation of the land through which they passed in the parish of St. Burgan so as to be subject to the rate. The case was argued some time ago by Mr. Meadows White, Q.C., and Mr. Moulton on behalf of the appellants, and Mr. Charles, Q.C., and Mr. Bullen on behalf of the respondents.—Mr. Justice Cave now gave judgment in favour of the appellants. He was of opinion that there was no such beneficial occupation as rendered the appellants liable to be rated for the relief of the poor.—The Lord Chief Justice, whilst entertaining some doubts on the subject, did not dissent from the conclusion arrived at by his learned brother.—Judgment was therefore given for the appellants, but leave was given to the respondents to appeal.

THE ELECTROLYTIC ESTIMATION OF LEAD AS LEAD DIOXIDE.—Mr. Frank Tenney, of the Massachusetts Institute of Technology, Boston, U.S.A., has undertaken a number of experiments to investigate anew the practicability of the determination of lead as lead dioxide in acid solution. The results are given as follow in the American *Chemical Journal*. The substance used for analysis in the present experiments was lead nitrate, whose purity was proved by estimating the lead. This was done by igniting the lead nitrate and weighing the residual oxide, PbO. Two determinations gave :—

| | I. | II. | Theory requires. |
|---|---|---|---|
| Weight $PbN_2O_6$ taken.. | 0·8005 ..... | 0·9713 | |
| Weight PbO found..... | 0·5395 ..... | 0·6542 | |
| Per cent. of Pb ..... | 62·5400 ..... | 62·5400 ..... | 62·54 |

A solution was made of this lead nitrate containing 1·4690 grams to the litre, and 25cc. of this solution were taken each time for analysis. Of this solution 25cc. should yield 0·0266 gram dioxide. In a neutral solution the lead was deposited partly as metallic lead on the negative, and partly as lead dioxide on the positive electrode. Three portions of the solution were then taken, and to No. I. 1½ per cent. of free nitric acid (calculated as anhydrous $HNO_3$), to No. II. 5 per cent., and to No. III. 10 per cent. were added. After sixteen hours' action of the current the amount of lead dioxide thrown down was found to be :—

| I. | II. | III. | Calculated. |
|---|---|---|---|
| 0·0216 ..... | 0·0253 ..... | 0·0265 ..... | 0·0266 |

The coating on No. 1 was not strongly adherent. In the next trial No I. received 10 per cent., No II. 13⅓ per cent., No. III. 16⅔ per cent. of free nitric acid. The results were:—

| I. | II. | III. | Calculated. |
|---|---|---|---|
| 0·0266 ..... | 0·0274 ..... | 0·0272 ..... | 0·0262 |

In the next trial 50 cc. solution of lead nitrate were taken and 10 per cent. of free acid added. The results were :—

| I. | II. | III. | Calculated. |
|---|---|---|---|
| 0·0533 ..... | 0·0533 ..... | 0·0452 ..... | 0·0532 |

In No. III., owing to irregularity of the current, the dioxide came down unequally and scaled off badly. A solution of copper containing 0·2920 gram copper in 25 cc. was made up, and three portions, each containing 25 cc. of this solution and 25 cc. of the lead solution, were subjected to the action of the current after adding to No I. 1½ per cent., No. II. 5 per cent., and to No. III. 10 per cent. of free nitric acid. The results were :—

| I. | | II. | | III. | | Calculated. | |
|---|---|---|---|---|---|---|---|
| $PbO_2$. | Cu. | $PbO_2$. | Cu. | $PbO_2$. | Cu. | $PbO_2$. | Cu. |
| 0·0278 | 0·2967 ... | 0·0281 | 0·2924 ... | 0·0275 | 0·2930 ... | 0·0266 | 0·2920 |

The copper was in all cases slightly black. In presence of iron with 1½ per cent., 5 per cent., and 10 per cent. of free acid, the results were :—

| | I. | II. | III. | Calculated |
|---|---|---|---|---|
| $PbO_2$..... | 0·0261 ... | 0·0259 ... | 0·0200 ... | 0·0266 |

The last one scaled off badly, thus accounting for the low result. The electrodes used had areas of 73·13, 75·19, and 66·49 square centimetres respectively. To sum up, one may say this method is reliable where the amount of lead is not too large and where there is a sufficient amount of free nitric acid present. Where the lead does not exceed 0·02 gram, it may be thrown down as lead dioxide and weighed on ordinary flat electrodes. Where larger amounts are present, aliquot parts of a solution must be taken, or a platinum dish may be made the positive pole and the dioxide washed by decantation. Since these experiments were made, this method has been largely used in the laboratory of the Massachusetts Institute, for the estimation of lead in galena, and in slags and mattes. From 10 per cent. to 20 per cent. of free nitric acid should be present; if there is too much, the lead dioxide, as fast as it is thrown down, re-dissolves in the nitrous acid resulting from the decomposition of the strong nitric acid. In slags and mattes, the most satisfactory method is found to be as follows: —After decomposition in the usual way, the lead and copper are precipitated as sulphides with sulphuretted hydrogen; these sulphides are dissolved in nitric acid, and the solution put in the circuit. A perfect and complete separation of the lead and copper is obtained. The small amount of sulphuric acid formed by the solution of the sulphides in nitric acid does not affect the accuracy of the determination.

AN ELECTRIC LIGHTING CASE.—STOCKMAN V. MUIR.—This case, the details of which are interesting to electric light engineers, and amusing into the bargain, was finally decided in Edinburgh on March 6th. In 1882 Mr. Stockman, a civil engineer in London, accepted a contract to light Mr. Muir's house on the island of Inistrynich, Loch Awe, with one arc and from 35 to 40 incandescent lamps, and completed his undertaking in September of that year, the price agreed upon being £320, Mr. Muir finding engine, boiler, and driving gear. A Siemens shunt dynamo was employed, but the gearing provided did not meet with Mr. Stockman's approval, as with it the engine had to be driven so slowly that the governor did not come into play; but the defender did not think fit to alter it, preferring to trust to the skill and watchfulness of his engineer. After working well for some weeks, the lamps in the billiard room suddenly went out, and refused to relight. Mr. Muir, instead of obtaining the services of an electrician, employed a plumber to discover and remedy the defect. After divers attempts at finding the fault, during which most of the billiard room fittings, pendants, &c., were taken down, it was found that when the switch which controlled the billiard room lights was cut out the lamps would burn. The plumber thereupon connected the billiard room system direct to the main wires. But very shortly the billiard room lamps failed again, and this time every lamp in the house followed suit, suffering simultaneous extinction, and leaving the place in darkness. Now the plumber was at fault, and after industriously taking down and altering the wires for some days, gave it up as a bad job. Thereupon Mr. Muir refused to pay Mr. Stockman's account on the plea of bad workmanship. Legal proceedings were taken, and Mr. Alfred R. Bennett was commissioned to examine and report upon the installation. This gentleman found that the original failure of the billiard room lamps had been caused by the fusing of the safety wire in the switch which controlled them, owing to the engine having been over driven; and that the second and final failure had been occasioned by a short circuit in the billiard room between two wires which had been unskilfully manipulated by the plumber. The second failure—the switch having been cut out—was of course followed by the extinction of every lamp in the house. The billiard room wires, which had been short circuited, bore signs of great overheating, the insulation being melted and charred. With these facts before him Lord McLaren gave judgment in November last in favour of Mr. Stockman, with expenses. Mr. Muir appealed, with the result that the judgment has been unanimously confirmed by the four judges of the Inner Court, with additional expenses. The *élite* of the Scotch Bar have been employed in the case, the Lord Advocate (Mr. Balfour, M.P.) representing Mr. Stockman, and the Dean of the Faculty (Mr. Macdonald) Mr. Muir. The defender has consequently been heavily mulcted. It was stated in court that the cost of a new pulley of the size desired by Mr. Stockman, which would have rendered overdriving impossible, was £2.

## AN IMPROVED THERMO-ELECTRIC PILE FOR MEASURING SMALL ELECTROMOTIVE FORCES.*

BY G. GORE, F.R.S., LL.D.

In the sketches (Figs. 1 and 2) A A′ and B B′ are four similar bars of oak, 20in. long, 1½in. deep, and ¾ths of an inch wide. A and A′ have each a sloping projecting ledge C, 16½in. long, and ¼in. wide. B and B′ have also a corresponding but flat projecting edge of the same width and length. The four bars are made of a bent shape, A A′ being concave on their upper edges and convex on their lower ones, and B B′ being the reverse, so that on squeezing the four bars powerfully together at their ends, they press against each other strongly at their middle parts as well as at their ends and become straight.

Between the bars, which are about 2¾in. asunder, and fixed to the lower ones, are two cross pieces of board D D, one at each end, each being 4½in. long, 1½in. wide, and ⅜in. thick; they hold B and B′ together. The lower bars are also united at their middle parts by a cross-bar of wood. A longitudinal strip of oak, E, 17in. long, ⅝ths of an inch wide, ¾in. deep, and rounded on its upper surface, is fixed at its ends to the middle parts of the pieces D D. The ends of the four bars A A′ and B B′, are securely held together by means of four bolts and nuts, as shown in the sketch. The wooden frame is also provided with four short legs.

The frame being made, and varnished upon all parts except the opposed edges, the upper bars are removed, and the upper edges of the two lower ones coated with glue, and allowed to dry. Two parallel wires of sufficient length, the total weight of each being four or five ounces, one being of iron ·55mm. diameter, and covered with cotton, the other, of the best quality of "nickel silver," ·70mm. diameter, and not covered, are then very tightly wound, with great care, side by side, and very closely together, transversely round the lower bars throughout 16½in. of length of the projecting edge, and the ends of the wires secured. The number of turns of double wire is about 300.

The lower edges of the upper bars and the corresponding opposed surfaces of the wire coil being now perfectly coated with hot glue, the upper bars are at once replaced in position, and the whole clasped tightly together by means of the bolts, so as to retain all the coils securely.

When the glue has dried, all the coils of wire on each side of the frame are cut off in a perfectly straight line at a distance of about 1¼in. below the projecting ledge C. The twelve hundred ends of wire are then soldered together as thermo-electric couples in proper order, so as to form one continuous conductor, and the series of ends on each side of the frame formed into two rows by bending each alternate couple, so as to prevent the ends of the couples touching each other.

The apparatus is movable; when in use it is supported by the lower edges of the bars B B′ resting upon the edges of two rectangular tin troughs, into which the ends of the couples dip. In using it, one set of the junctions is heated to between 120° and 130° C. in melted paraffin, contained in one of the troughs, and the other set is kept at atmospheric temperature by immersion in non-volatile petroleum, known as "thin machinery oil," in the other trough. Water-baths are quite unsuitable. P and N are the positive and negative terminal screws; the screw at the distant end is also a negative one,

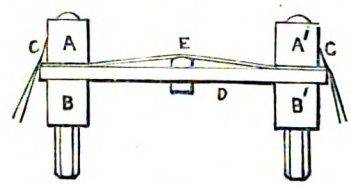

Fig. 2.—Section of Thermo-Electric Pile.

and is only used when the pile is joined in series with a second one. The glue with which the wires are secured to the frame serves to prevent the oil ascending by capillary action, and the openness of the wooden frame beneath the wires helps to keep the latter cool.

Contact is made with a greater or less number of pairs by attaching a thin copper wire, with a thin strip of brass on its end, to one of the terminal binding-screws P, and sliding its free end *across* the wires in a longitudinal direction above the central strip of wood E. The number of pairs in circuit is ascertained by means of a divided scale which is above the wires and fixed to the frame.

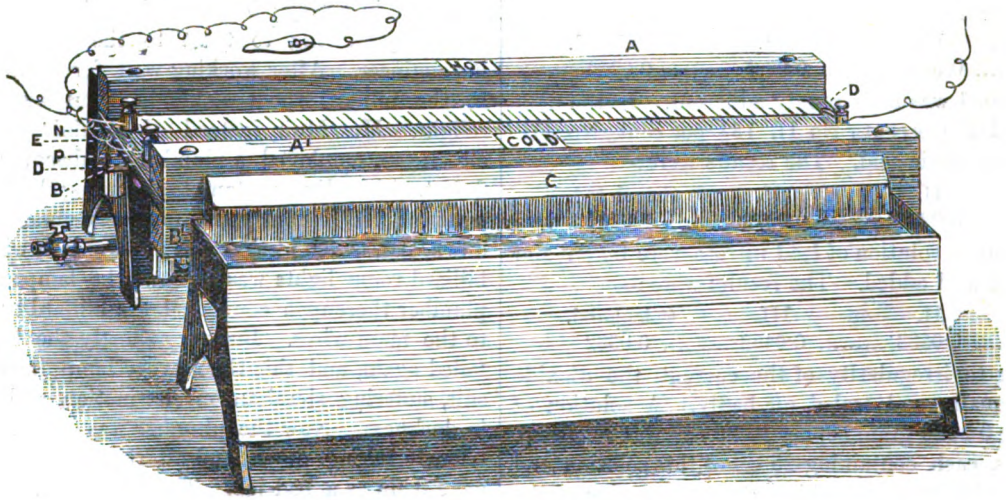

Fig. 1.—New Thermo-Electric Pile.

An apparatus constructed thus, and consisting of 295 pairs, had a resistance of 95·6 ohms at 16° C., and by a difference of 100 C. degrees of temperature of the two baths yielded a current having an electromotive force of ·7729 volt; or, with a difference of 130 C. degrees, 1·005 volt; each element therefore equalled ·0000262 volt for each C. degree difference of temperature.

As iron and German silver, unlike bismuth and antimony, do not alter much in electromotive power by long-continued use within the above limits of temperature, it is probable that, after having been properly verified with a standard voltaic cell, such an apparatus, or any fraction of it, may itself be employed as a standard. It is capable of producing and measuring, within the above range, differences of 26 millionths, or $\frac{1}{38461}$ of a volt.

Having constructed several of such apparatuses, and used them in making a large number of measurements, I can testify to their practical utility. Measurements of currents from moderately steady sources have repeatedly been made at a rate of fifteen per hour by means of them. For greater electro-

* Read before the Birmingham Philosophical Society, February 14, 1884.

motive forces sometimes two piles and a single hot bath were employed.

An apparatus on the same principle was constructed by M. Jules Regnault (*Comptes Rendus*, Vol. XXXVIII., 1854, pp. 38-42; *Annales de Chimie*, Vol. XLIV., 1855, pp. 453-494; Deschanel's "Natural Philosophy," by Everett, 1872, p. 678), but it has not come into general use in England. It consisted of sixty bismuth and copper elements, 176 of which were equal to one Daniell cell.

S. Holden, War-lane, Harborne, Birmingham, undertakes the construction of the present instrument.

## ELECTRIC LIGHTING IN FINLAND.

One of the most important installations of lighting by electricity outside the United Kingdom is that of which we give illustrations this week by the Manchester Edison Company at the works of Messrs Finlayson, in Finland, the engineers being Messrs. Mather and Platt, of Manchester.

The dynamos are those of the ordinary Edison type, consisting of two 250 lights, two 60 lights, and two 15 lights each, driven by countershaft gearing mounted upon wall boxes and brackets about 8ft. 6in. from the level of the ground. Our illustrations (Figs. 1 and 2) represent in the first instance the arrangements of the entire machinery, including perspective view (Fig. 3) of a powerful and compactly designed compound condensing engine, which transmits power through a 12in. "link" belt, the further transmission of power to the electrical machinery being shown in our plan drawing (Fig. 1).

The cylinders are in one casting, the low piers being 19in. bore, and the high piers 12in., with a stroke of 1ft. 7in. The joint between the two cylinders is composed of a loose stuffing box fitted with elastic metallic packing and gland. The pistons are Mather and Platt's patent, also having metallic packing and steel coils. Each cylinder is provided with main and cut-off valves worked by separate excentrics, and expansion valves regulated by a "Porter" governor, the general arrangement of which is the same as that given in our notice of the 12th January last of the Mount-street installation in Manchester by the same firm. A cast-iron crank disc is shrunk on the fly-wheel shaft. The fly-wheel pulley is very massive, 13in. broad on the face, with recesses in the sides of the rim, for convenience of "turning gear," and an injection condenser mounted behind the engine completes the motive power.

Referring to the gearing, it will be seen in our illustrations that in each case the dynamos are provided with one pulley

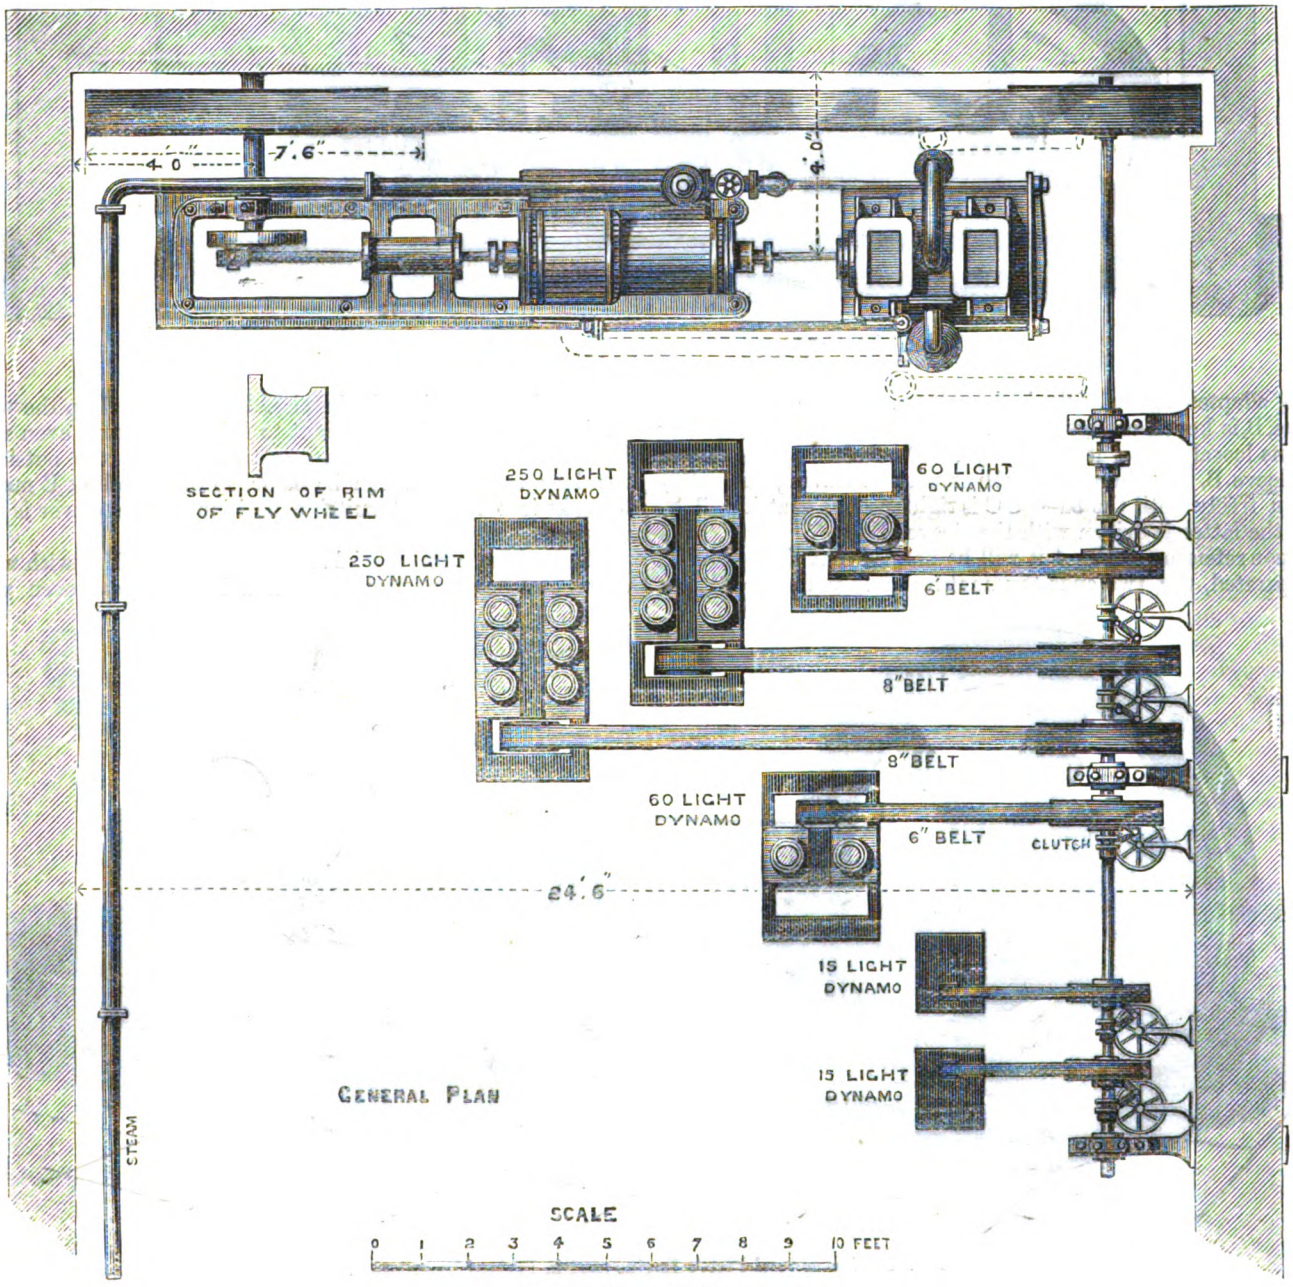

FIG. 1.—Machine Room, Finland Installation.

Digitized by Google

only on the countershaft, each of which is fitted with Messrs. Mather and Platt's patent friction clutch similar to those in the engravings on p. 417, Messrs. Mather and Platt claiming that this installation shows very advantageously the successful adoption of this gear in place of the ordinary method of fast and loose pulleys.

Fig. 4 shows a complete exterior, and Fig. 5 a section of the same, adapted to use with single pulleys. In the first place a sleeve, B, is keyed on to the main shaft, and the wheel at pulley A runs loosely upon it. The band C C is bolted to the disc of the sleeve B, and therefore revolves with it, leaving the pulley to run freely until the band C C is tightened, so that it will be seen the latter is driven with the sleeve B.

Upon referring to Fig. 4 it will be noticed that the band C C is separated, the two ends terminating in lugs, distance being allowed between them for the interposition of a screw, which is fitted with right and left-handed threads, so that it will be readily understood by a slight movement of the screw S that the distance between the lugs must increase or decrease as may be required; hence, it will be seen, a rigid connection must be formed between the sleeve and the wheel, the clearance at any time, when slack, being only about $\frac{1}{32}$nd of an inch.

To effect the movement of the screw threads S, the slide F can be slid to and fro along the shaft by means of levers or screw and hand wheels commonly in use. When pushed towards the pulley in the direction of the arrow, the consequent alteration in the angle of the link E lifts the lever D, which is rigid with the body of the screw threads; these then, taking the position of the dotted line G, immediately close the two lugs, causing the band C C to firmly clasp the wheel A, developing friction sufficient to drive the latter, even when heavily loaded. By moving the two nuts on the outside of the lugs adjustment can be made, so that the link E may be brought into its most suitable position, where power is most required.

The makers direct special attention to the facility with which these clutches can be thrown in and out of gear, even when running at high speeds, and having compactness in view, they state that one of these clutches, occupying not more space than 36in. diameter by 30in. broad, gives greater driving power than an ordinary cone clutch 6ft. diameter. Dealing, however, with their use in connection with dynamo driving, as in the present instance, it is stated to be an accomplished fact that by their application all irregularities, shocks, and jars—and also the racing of machines, and consequent wear and tear—resulting

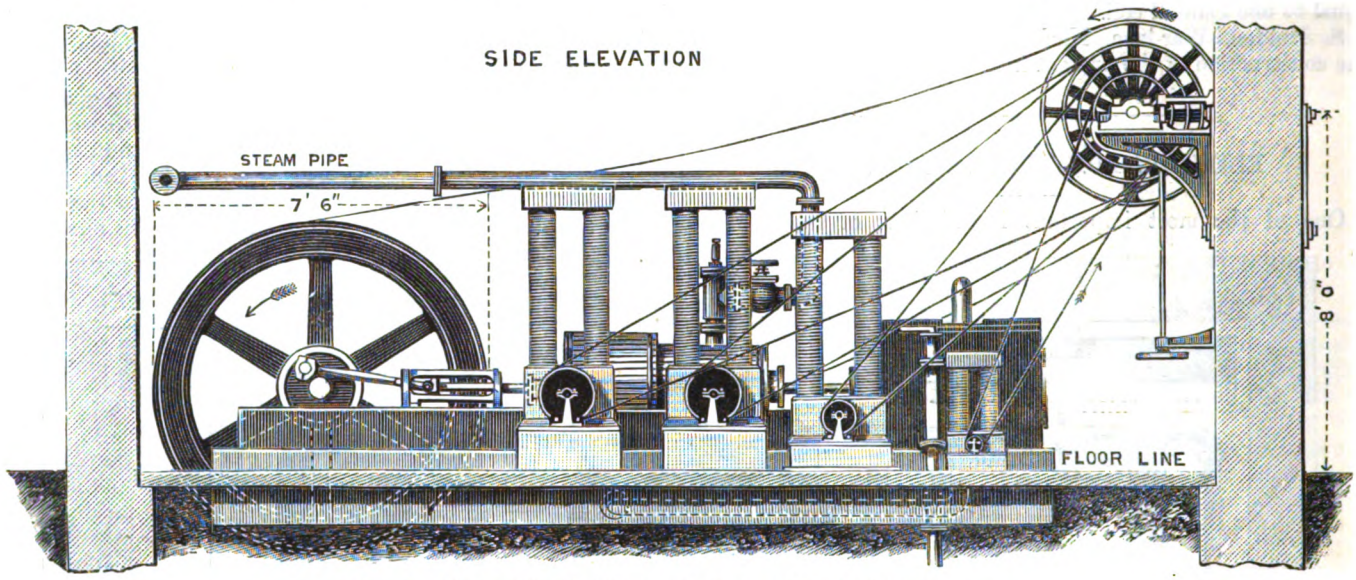

Fig. 2.—View of Machine Room, showing method of driving dynamos.

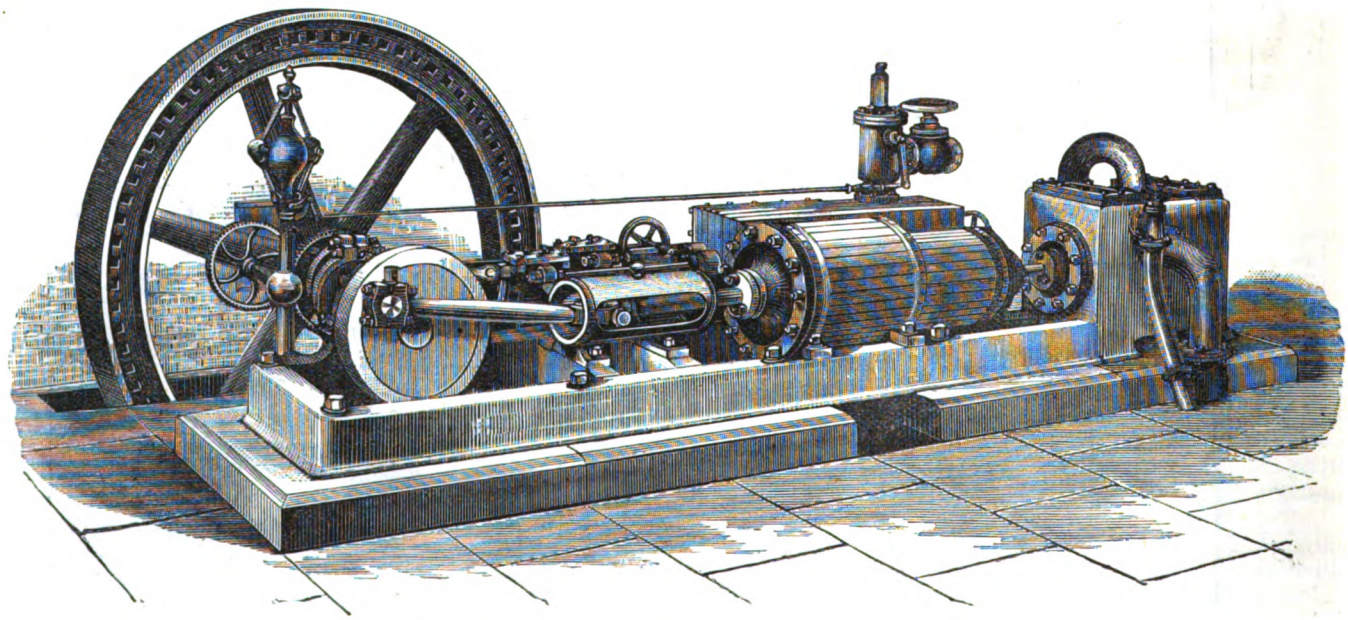

Fig. 3.—Mather and Platt's Engine used in Finland Installation.

from the old methods of fast and loose pulley driving, are to a very large extent avoided.

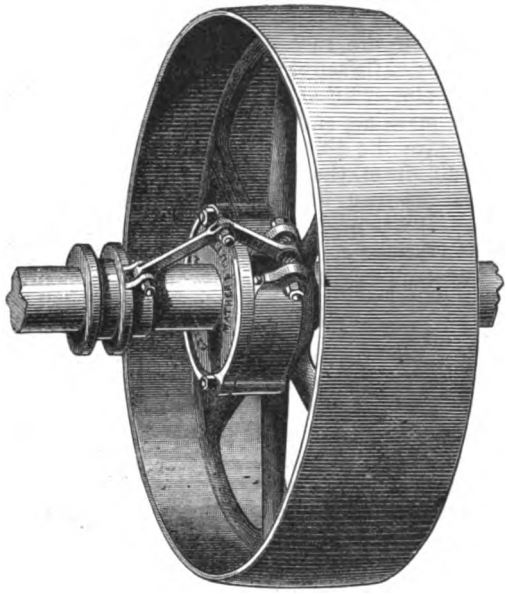

FIG. 4.—Mather and Platt's Friction Clutch.

We have not seen the installation, but we are told that its working after six months' trial is most satisfactory. We are, however, able to speak of the very excellent and powerful ap-

pearance of the engine, which we inspected previous to its departure from Messrs. Mather and Platt's works.

## RECENT PROGRESS IN DYNAMO-ELECTRIC MACHINES.*

By Professor SILVANUS P. THOMPSON, B.A., D.Sc., M.S.T.E.
University College, Bristol.

Fifteen months ago, I had the honour of delivering in this place a course of three Cantor Lectures on "Dynamo-electric Machinery." In the first of those lectures, the endeavour was made to trace out a physical theory of the action of dynamos, and to follow the theory into its bearings upon the construction of such machines. In the second lecture, a large number of actual machines were considered and compared with one another and with the theory; and in the third lecture, the dynamo was considered in its functions as a mechanical motor.

As the present paper may be considered supplementary to the Cantor Lectures, it will be convenient to treat of the features of progress which come to-night under review in a similar order of topics. I therefore take up first the theory of the dynamo.

There are, in fact, three distinct theories of the dynamo: (1) a physical theory, dealing with the lines of magnetic force and lines of current in which these quantities are made, without further inquiry into their why or how, the basis of the arguments; (2) an algebraical theory, founded upon the mathematical laws of electric induction and of theoretical mechanics; and (3) a graphical theory, based upon the possibility of representing the action of a dynamo by a so-called "characteristic" curve, in the manner originally devised by Dr. Hopkinson,

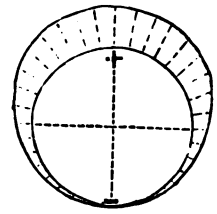

FIG. 1.—Diagram of Potential round Collector of Dynamo.

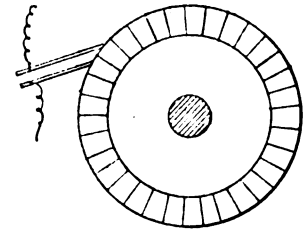

FIG. 3.—Method of Experimenting at Collector of Dynamo.

and subsequently developed by Frölich, Deprez, and others. The last of these three methods, though it has not received any great or striking development during the past year, has proved itself to be the most invaluable aid in the practical construction of dynamo machines. One has only to refer to the use made of characteristics by Mr. Kapp in his articles on the winding of "compound" dynamos, and, still more recently, by Dr. Hopkinson, in solving certain problems in the electric transmission of energy, to see how invaluable the method is.

In the algebraic theory much progress has been made during the past year; and there certainly was room for it. Monsieur Joubert has published, in the *Journal de Physique* for July, 1883, a long mathematical article, the object of which is to deduce the equations of the dynamo, taking into account not only the action of self-induction in the circuit, but also some of the terms of the second order usually neglected in first approximations. It is a question whether he has not still omitted some terms of quite as great an importance as those retained in the complicated formula deduced by him. But the matter can hardly be discussed in the present paper. Still more recently, Professor Clausius has published in Wiedemann's *Annalen*, for November last, a paper expounding a mathematical theory of dynamo-electric machines far more comprehensive, and, I venture to say, far more true, than any other yet

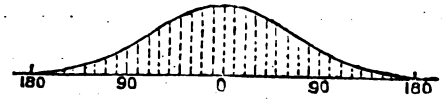

FIG. 2.—Horizontal Diagram of Potentials at Collector of Gramme Dynamo.

put forward. Without shirking any of the mathematical difficulties presented by the complications of mutual induction between, and self-induction in, the various organs of the machine, and by the admitted incompleteness of all our formula for connecting the magnetism of an electro-magnet with the strength of its exciting current, Professor Clausius has succeeded in putting the equations into a shape, not only far more satisfactorily from the point of view of completeness, but in framing those equations in a manner that must commend itself to every engineer. The relative simplicity attained by Clausius is, in fact, due to his lavish introduction of a set of arbitrary constants, each one of which having values that must be determined by experiment for each machine or type of machines. The number of new symbols thus introduced is considerable; and it would be very desirable to find names for the separate constants to be determined. An excellent translation has appeared in the *Philosophical Magazine* of this year, and another is in process of publication in *The Electrician*, in which journal the

* Paper read before the Society of Arts, Feb. 28, 1884

Digitized by Google

series of articles on the theory of dynamo-electric machines from the pen of Professor O. J. Lodge is still continued. It cannot be said even yet that the mathematical theory of the dynamo is near completion. A further paper by Professor Clausius is promised; and it remains to be seen whether this article will deal with some of those points in which the graphic method has been so useful in practice, for example, in determining the proper quantities of wire for the coils in "self-regulating" or "compound" machines, and in finding the best shape to give to magnets and pole-pieces.

Turning to the physical theory of the dynamo, there is much to record. Our knowledge of the inductive actions which go on between the field-magnets and armatures of dynamos has received considerable additions during the past year from the researches of Isenbeck, Cunnynghame, Pfaundler, and others. There is a good deal to be said on this head, and I have several new results to announce as the result of my own observations. Let me take as my starting point a matter mentioned in my Cantor Lectures, namely, the distribution of potential round the collector or commutator of a dynamo. Mr. W. M. Mordey, who first drew my attention to the fact that this distribution was irregular in badly designed machines, had devised the following method of observing it. One terminal of a voltmeter was connected to one of the brushes of the dynamo, and the other terminal was joined by a wire to a small metallic brush or spring, which could be pressed against the rotating collector at any desired part of its circumference. I then made the suggestion that these indications might with advantage be plotted out round a circle corresponding to the circumference of the collector. Figs. 1 and 2, which are reproduced from my Cantor Lectures, serve to show how the potential in a good Gramme machine rises gradually from its lowest to its highest value. The same values as are plotted round the circle in Fig. 1 are plotted out as vertical ordinates upon the level line in Fig. 2. I made the remark at the time that if the magnetic field in which the armature rotated were uniform, this curve would be a true "sinusoid," or curve of sines; and that the steepness of the slope of the curve at different points would enable us to judge of the relative idleness or activity of coils in different parts of the field. About the same time, I developed this method of observation a little further, and used two small metal brushes, at a distance apart equal to the width between the middle of two consecutive bars of the collector of my little Siemens dynamo, for the same purpose.* As the collector rotated, these two little brushes (see Fig. 3) gave on the voltmeter an indication which measured exactly the activity of the induction, in that section of the armature which was passing through the particular position in the field corresponding to the position of the contacts. I found, in the case of my Siemens dynamo, that the result was fairly satisfactory, for the difference of potential indicated was almost *nil* at the sections close to the proper brushes of the machine, and was a maximum about half way between. In fact, the difference of potentials was rising most markedly at 90° from the usual brushes, or precisely in the region where (as seen in Fig. 2) the slope of the curve of total potential was greatest. One immediate result of Mr. Mordey's observations on the distribution of potential, and of my method of mapping it, may be recorded. I pointed out to Mr. Mordey that in a dynamo where the distribution was faulty, and where the curves of total potential showed irregularities, the fault was due to irregularities in the induction at different parts of the field; and that the remedy must be sought in changing the distribution of the lines of force in the field by altering the shape of the pole pieces. I am able now, after the lapse of fifteen months, to congratulate Mr. Mordey on the entire and complete success with which he has followed out these suggestions. He has entirely cured the Schuckert machine of its vice of sparking. The typical bad diagram given in my Cantor Lectures was taken from a Schuckert machine before it received from his hands the modifications which are so signally successful to-day.

Fig. 5.

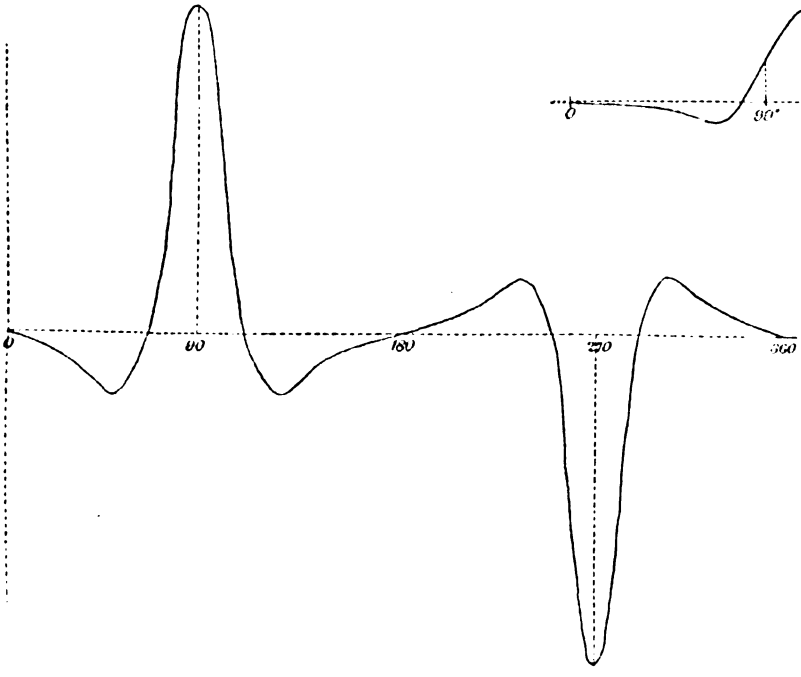

Fig. 6.

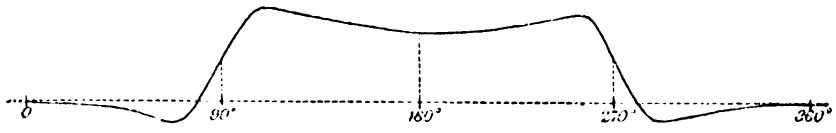

Fig. 4.—Isenbeck's Apparatus.

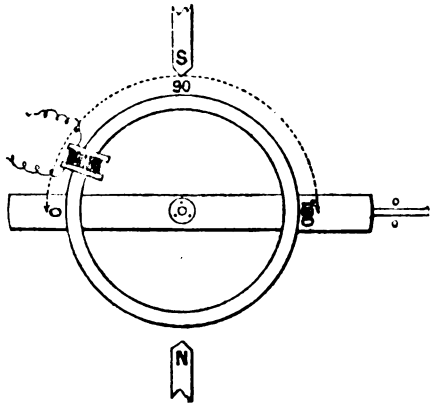

Since the experiments above detailed, I have experimented on my Siemens dynamo in another way. The machine was dismounted, and its field magnets separately excited. Two consecutive bars of the collector were then connected with a reflecting galvanometer having a moderately heavy and slow moving needle. A small lever clamped to the collector allowed the armature to be rotated by hand through successive angles equal to 10°, there being thirty-six bars to the collector. The deflections obtained of course measured the intensity of the inductive effect at each position. The result confirmed those obtained by the method of the two wire brushes.

I mention these methods, which have been used in my laboratory at Bristol, and have not been published before, because they relate strictly to the physical theory of the dynamo as developed in my Cantor Lectures, and also because of their practical application to all dynamos in which any such defect appears. They are also very closely related to the researches of Dr. Isenbeck, which next claim attention.

Dr. Isenbeck described, in the *Electrotechnische Zeitschrift* for last August, a beautiful little apparatus for investigating the

* Dr. Isenbeck has also independently used a similar arrangement to investigate the induction going on in a Gramme dynamo.

Digitized by Google

induction in the coils of a Gramme ring, and for investigating the influence exerted by pole pieces of different form upon these actions.

Isenbeck's apparatus (Fig. 4) consists of a circular frame of wood placed between the poles of two small bar-magnets of steel, each 25 centimetres long, lying 25 centimetres apart. On the frame, which is pivotted at the centre, is carried a ring of wood or iron, upon which is placed at one point a small coil of fine wire. This corresponds to a single section of the coils of a Pacinotti or of a Gramme ring, of which the ring of wood or iron constitutes the core. The coil can be adjusted to any desired position on the ring, and the ends communicate with a galvanometer. On vibrating it isochronously with the swing of the needle of the galvanometer, the latter is set in motion by the induced currents, and the deflection which results shows the relative amount of induction going on in the particular part of the field where the coil is situated. The vibrations of the frame are limited by stops to an angle of 7° 5′. Pole pieces of soft iron, bent into arcs of about 160°, so as to embrace the ring on both sides, but not quite meeting, were constructed to fit upon the poles of the magnets. In some of the experiments a disc of iron was placed internally within the ring; and in some other experiments a magnet was placed inside the ring, with its poles set, so as either to reinforce, or to oppose, the action of the two external poles. In Dr. Isenbeck's hands this apparatus yielded some remarkable results. Using a wooden ring, and poles destitute of polar expansions, he observed a very remarkable inversion in the inductive action to take place at about 25° from the position nearest the poles.

Fig. 4 is a sketch of the main parts of Isenbeck's instrument, and shows the small coil mounted on the wooden ring, and capable of being vibrated to and fro between stops. When vibrated at 0°, or in a position on the diametral line at right angles to the polar diameter, there is no induction in the coil; but as the coil is moved into successive positions round the ring towards the poles, and vibrated there, the induction is observed first to increase, then die away, then begin again in a very powerful way, as it nears the pole, where the rate of cutting the lines of force is a maximum. This powerful induction near the poles is, however, confined to the narrow region within about 12° on each side of the pole. It is beyond these points that the false inductions occur, giving rise in the coil, as it passes through the regions beyond the 12°, to electromotive forces opposing those which are generated in the regions which are close to the poles.

These inverse inductions were found by Isenbeck to be even worse when an iron disc, or an internal opposing magnet, was placed within the ring; but a reinforcing magnet slightly improved matters. Of course such an action in a Gramme armature going on in all the coils, except in those within 12° of the central line of the poles, would be most disastrous to the working of the machine; and the rise of potential round the collector would be anything but regular. In Fig. 5 I have copied out Isenbeck's curve of induction for the consecutive four quadrants. From 0° to 90° the exploring coil is supposed to be vibrated in successive positions from the place where, in the actual dynamo, the negative brush would be, round to a point opposite the S pole of the pointed field magnet. From 90° to 180° it is passing round to the positive brush; from 180° to 270° it passes to a point opposite the N pole; and from 270° to 360° returns to the negative brush. Now, since the height of this curve, at any point, measures the induction going on in a typical section as it moves through the corresponding region of the field, and since in the actual Pacinotti or Gramme ring the sections are connected all the way round the ring, it follows that the actual potential at any point in the series of sections will be got by adding up the total induced electromotive force up to that point. In other words, we must integrate the curve to obtain the corresponding curve of potential corresponding with the actual state of things round the collector of the machine. Fig. 6 gives the curve as integrated expressly for me from Fig. 5 by the aid of the very ingenious curve integrator of Mr. C. Vernon Boys.

(TO BE CONTINUED.)

## TRANSMISSION OF THE NEW OPERA "LAURIANA" BY THE TELEPHONE.

On Saturday last the Edison-Gower-Bell Telephone Company in Lisbon had the honour of transmitting the above opera by telephone to the Ajuda Palace of the King of Portugal.

As it was the first performance in Portugal of this opera, the composer of which is a Portuguese, the King and Court were much distressed at being unable to attend, owing to the recent decease of the Princess of Saxony. However, the difficulty was overcome by the opera being transmitted by telephone. The arrangements at the Opera House were as follow:—A, B, C, D, E, F (Fig. 1) represent six microphone transmitters connected in multiple arc, A and F being Blake transmitters and the remainder Gower-Bell. A, B, E, F were placed on the bases of the columns in front of the curtain, about six feet above the stage.

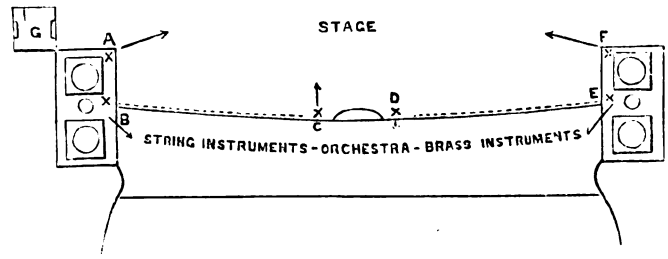

Fig. 1.

C and D were one foot above the stage, on either side of and behind the footlights. All the instruments were placed on lead supported by soft india rubber pedestals, in order to lessen as much as possible the effects of extraneous vibrations. The arrows indicate the direction in which the transmitters faced. A metallic circuit of ten miles of wire was employed, one of the lines entering the box, as shown in Fig. 2, from which plan all the connections of the lines will be readily understood. Thus any transmitter could be cut out without disturbing the remainder. Each transmitter had three sets of two Leclanché batteries, which were switched on in succession every twenty minutes, on account of the rapid polarisation of these batteries when on short circuit. Whenever the bass and more metallic instruments of the orchestra were brought into full play, the transmitters D, E, and occasionally C, were cut out, to avoid the jarring effect which would otherwise have been produced. In Fig. 2, L, M,

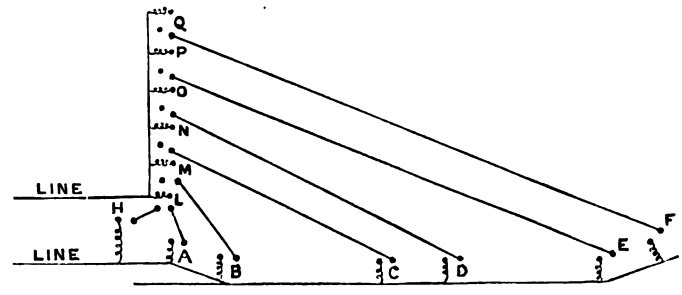

Fig. 2.

N, O, P, Q represent six two-way switches. After each act, by switching L to the left, a Gower-Bell transmitter and receiver, H, were put in circuit, and by a similar arrangement at the Palace conversation was carried on. At the receiving end, in the Palace, ten Gower-Bell receivers were placed along a table covered by a handsome plush velvet table-cloth, with gold embroidery. Behind the receivers were grouped a beautiful collection of hot-house plants, ferns, and silver vases full of choice flowers and fruits, and a couple of exquisite lamps which lit up the whole. The telephones themselves were hidden from view by flowers, from which emerged the two ear tubes of each receiver. Along the front of the table was a velvet cushion on which to rest the arms. The whole of the Royal family and a distinguished party heard the opera by these means. The King expressed his complete satisfaction. The arrangements were under the direction of Mr. Alan Danvers, the company's representative and engineer in Lisbon.

## THE PROGRESS OF ELECTRIC LIGHTING.

Any words of reassurance with regard to the progress and prospects of electric lighting are exceedingly welcome just now, and the paper bearing the title which heads this article, delivered at the Society of Arts last Wednesday week, was not only well intentioned but well timed. Mr. Preece has never been amongst those over sanguine leaders of public opinion who, to a larger extent than he seems to admit, share the responsibility of failure, if not of electric lighting, of electric lighting projects. When, therefore, he steps forward as a champion of the light, confidently pronouncing it a success, his words deserve to be listened to. Papers read at the Society of Arts have generally a practical object in view, and Mr. Preece's paper was pre-eminently practical, in that it showed the true causes of apparent failure, and the sure road to future success. It may be feared that his encouragement as well as his warning have come a little late; but, on the other hand, if all had gone smoothly, neither the one nor the other would have been needed, and we may be thankful that the task has been undertaken by a trusted and popular lecturer.

Mr. Preece led off with a quotation which furnished the text for the whole paper. Somebody prominently connected with an electric lighting company had publicly stated that the electric light was at present a failure, and that the sooner the public were made aware of it the better for their pockets, a statement which the public are at the present moment very much inclined to endorse, but which Mr. Preece combated with much vigour and truth. Electric lighting is, he said, a success, and he proved it beyond question in the course of the evening. It is true that the electrical success of the light is one thing, while its success as a commercial commodity is quite another, and it was certainly to this latter aspect that the speaker at the bankrupt company's meeting was referring; but his denunciation was far too sweeping. It is highly important that the two things which the public have been persuaded to confound as one should be clearly distinguished; and this was what Mr. Preece set himself to do most strenuously. What has proved a failure—a disastrous failure—is electrical company-mongering, and electric lighting finance. It was these that had failed, and it was the failure of these alone that makes people button up their pockets directly the electric light is named. Nothing, perhaps, that the lecturer added was calculated to induce them to relax their purse strings, at all events not incautiously, just yet awhile; but what he insisted on their doing was to reopen their ears and listen to facts relating to the electric light itself, to rehabilitate it as a scientific achievement, and to re-establish it in public estimation as a beautiful, a wholesome, desirable, and a practical means of illumination. Even in the matter of cost he showed that progress was being made in economising the production, although wisely dwelling more upon the merits of the light as a luxury which may soon be considered indispensable than upon its cheapness, which is at present problematical. When a luxury is wanted people will pay for it if the price is not prohibitive; and they will have the electric light, not because it is cheap, but because it is safe, healthy, pure, soft, and convenient. This much can, at all events, be said of the incandescent, or, as Mr. Preece prefers to call it, the "glow" lamp; and we quite agree with him that if the light were supplied on a rational principle, by competent hands, the demand for it would be prompt and general. With regard to the arc light, the case is somewhat different, coming as it does in direct conflict with gas for street lighting, its superiority being by no means universally admitted, and its cost being a serious consideration for the taxpayers. But even for this purpose arc lighting has a hopeful future before it, seeing that improvements in the means of producing it are progressing very rapidly. What, however, it must be content with at present is to find scope for its utilisation, and this it may do in the great squares, public halls, railway stations, factories, and wherever outdoor work is going on at night time.

All this, however, was known from the very first. How comes it, then, that the electric light has, so far, proved a complete failure? Two causes mainly have contributed to this result. One we have mentioned already, and Mr. Preece applied language to it which, strong as it is, is fully justified. The business of electric lighting "has been disgraced by the commission of every crime that commercial immorality could invent." This of itself would account for the discredit into which the business has fallen. There is no need to add reproaches against the speculative mania of the public; we fear, indeed, that others besides "ravenous promoters" were far from blameless in this respect. There was a mental speculative mania, amounting in some

Digitized by Google

quarters to moral aberration, as well as a financial mania, and without which the ravenous promoter could not have prospered. The lecturer himself approached the question with clean hands; that he did not speak what was probably in his mind was natural enough; but we think he might have spoken words of pity rather than of blame about the misguided public who put their trust not in the unsupported words of the promoter but rather in the tacit and sometimes open patronage of the scientist. The financier has no character to lose; he stands in public estimation now pretty much as he stood before the speculative mania set in. But with regard to the scientific world the case is different, and we repeat what we have said on many occasions previously—that it will take a long time to restore confidence to the public mind in the judgment of those on whose declarations and predictions it has vainly relied.

The other cause of failure is the Electric Lighting Act. We deprecated this measure while it was being framed; we protested against it when it was completed, and we have never lost an opportunity of condemning it ever since. It is with much satisfaction, therefore, that we find Mr. Preece following in our footsteps. The failure of the Act, like the failure of many legislative interferences of a similar kind, is a matter of small moment; but the failure of electric lighting businesses is a grievous matter, and it can be directly traced in a great degree to the precipitous and superfluous action of Mr. Chamberlain. The fanatical dread of monopoly has resulted in there being no business either to monopolise or compete for. In its professed solicitude for the consumers the Act has deprived them of what they were anxious to obtain, and willing to buy on their own terms. Never was there such a perfect example of improving off the face of the earth. Of the hundred or more provisional orders applied for last year not one has been carried out or attempted; of the ten applications for licenses but one has been persevered with, the only other signs of action in this line of business being in the City of London where the Act is deliberately ignored. It is said that some of its restrictions are to be relaxed; in estimating the future prospect of electric lighting as a business much will depend on what concessions can be extorted from the office of the Board of Trade. But apart from this the electric light, as a light, is a proved success, and its future is sufficiently well assured.

## RESISTANCE EXPRESSED AS A VELOCITY.

We think it but just to Mr. Dobson that special attention should be directed to the experiment devised by him, as described on p. 376 of the present volume. So far as we know this is the first time that such an experiment has been successfully attempted, and should imagine that the Dobson experiment will, in future, find a place in every course of lectures on electricity. Mr. Dobson is a student at the School of Electrical Engineering, and the lecture to which he refers was one given by the Editor, who took as his text certain paragraphs on this subject given in Atkinson's translation of "Mascart and Joubert," Vol. I., a work that should be in the hands of every student, and which has been awaiting the issue of Vol. II. for notice in these columns. We think it would be interesting if Mr. Dobson and others who may attempt the experiment would formulate a table for various resistances. Concrete illustrations of some of the abstract views put forward by theorists are of incalculable value to the student, hence the praise due to Mr. Dobson for the illustration he has devised.

# CORRESPONDENCE.

## THE PHYSICAL THEORY OF THE GRAMME MACHINE.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: In reference to the letter of Mr. E. L. Voice, under this heading, I have in the first place to observe that the theory I have put forward is by no means limited to machines of the Pacinotti type. The law of Lenz is in fact applicable to every case of electro-dynamic induction. Nor is there any contradiction between the "lines of force" theory and that which I have put forward; for the former has been devised with the express intention that it should harmonise in every point with the law of Lenz and the theory of Ampère. The question has been: Which theory gives the most direct and the most complete explanation of the phenomena observable in the Gramme machine?

I cannot admit the cogency of Mr. Voice's criticism when he says that I have "hopelessly mixed up" the amperian and the "lines of force" theories—"sometimes applying one theory when the other should be called in, and *vice versâ*." I am curious to know when and where I have applied the "lines of force" theory when the other should have been called in!

It appears to me that Mr. Voice is inclined to place himself in antagonism not only to the above-mentioned theories, but also to the principle of the Conservation of Energy. An admission or disclaimer in this connection on the part of your correspondent might very much simplify any discussion of the points at issue.

Mr. Voice is a skilled experimenter, and I am disposed to give respectful consideration to his experimental facts. But these of course must be taken in conjunction with other experimental facts before their theoretical bearings can be duly appreciated. This applies whatever may be the *primâ facie* difficulty in reconciling the results of two different experiments or sets of experiments. And it may be observed that very valuable knowledge may possibly be obtained in the endeavour to overcome such difficulty.

For instance, Mr. Voice gives a diagram of Faraday's disc machine indicating that radial currents in the same direction tend to pass not only in that portion of the rotating disc which is facing the pole, but also in those portions which are approaching and receding from the pole. According to this diagram the law of Lenz would seem to be at fault; and, consequently, since no (electrical or magnetic) resistance is opposed to the rotation of the disc, whilst electrical energy is undoubtedly generated, the law of the Conservation of Energy would also be at fault. But it was experimentally shown by Arago that the disc in its rotation tends to carry the magnetic pole with it; whilst Babbage and Herschel exhibited the converse phenomenon of the rotation of a disc by the effect of a magnet rotating beneath it. These facts constitute a sufficient vindication of the law of Lenz in the present case; and the theory advanced by Faraday in explanation of the observed effects is based upon the recognition of this law. According to this theory, circular currents, or their equivalent, resulting in magnetic polarities which oppose the motion of the disc (or magnet) are produced by the rotation. Referring to the figure, if the disc be rotating, in the direction indicated by the large arrow, in front of the south pole represented by the dotted S, the movement of electricity in those portions of the disc which are approaching the pole will be in a direction from the periphery towards the centre, or in the direction opposite to that of the amperian current approached. The general direction of this current is indicated on the radius *b*. The direction of the currents in those portions of the disc actually in front of the pole will be, as indicated upon *a*, the same as that of the amperian current from which those portions are receding, and opposite to that of the amperian current which is approached. Lastly, the direction of the flow in those portions of the disc which are receding from the pole will be as shown at *c*. By the first law of electro-dynamics there will be repulsion between *b* and the pole, and

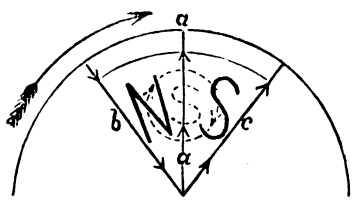
Digitized by Google

attraction between *c* and the pole. Again, if we take the currents *a* in conjunction with those indicated by *b*, we have *north* polarity on that face of the disc which is nearest to the observer, or *south* polarity—repelling the south pole—on that face which is the nearer to the magnet. Similarly, taking the currents *a* in conjunction with those represented by *c*, we have *north* polarity—attracting and attracted by the pole—on that face of the disc which faces the magnet.

Is, then, Mr. Voice entirely wrong in his diagram showing radial currents all in the same direction? Certainly not, in one sense at least; for experiment shows that the current indicated by the galvanometer is in the same direction whatever may be the position of the wire in contact with the periphery of the disc. Even if this wire be shifted to a point below the axis of suspension the direction of the current remains unaltered. But how can this experimental result be reconciled with the accepted theory? This is an interesting question, but one to which I cannot—this week at least—attempt to give a solution. To parody the dictum of Sir Lucius O'Trigger—'tis a very pretty *paradox* as it stands!

In his diagram and statements explanatory of the induction effects in the Ferranti armature, Mr. Voice is in accord both with the "lines of force" theory and the explanations which I prefer to adopt, excepting so far as he is in contumacy to the law of the Conservation of Energy.

In regard to the explanation offered as to the action of the Gramme machine, is Mr. Voice prepared to maintain that the varying polarities at given points at the ring have nothing to do with the observed inductive effect, and that this is almost entirely confined to the immediate vicinity of the field-magnet poles—supposing these to be of the relative dimensions shown in his diagram? Does he think it would be a good plan to



short-circuit all the (? idle) coils which are at a distance from the poles?

In conclusion, I do not quite see why Mr. Voice should conclude that I confound one thing with another in making the statement that the introduction of the neutral point of an electro-magnet within a coil is attended with a greater inductive effect than that resulting from the insertion of one of its poles.—Yours, &c., DESMOND G. FITZGERALD.

---

TO THE EDITOR OF THE ELECTRICIAN.

SIR: I read Mr. Voice's letter in your paper last week with great satisfaction, having followed most of the correspondence on the subject of "The Theory of the Gramme Ring," and having been very much confused thereby.

Some time ago I had occasion to make myself acquainted with a few of the simpler facts connected with dynamos, and not being at all enlightened by the explanation of the above theory given in such books as I was able to refer to, I tried two or three experiments (which I shall presently describe), and convinced myself at any rate that there must be two classes of dynamos—viz., those in which the current is generated by the reversal of the polarity of the revolving cores, and those which generate the current by the simple passage of the conductor across the face of a magnet (or, taking the revolving core into consideration, between the faces of two magnets of opposite polarity).

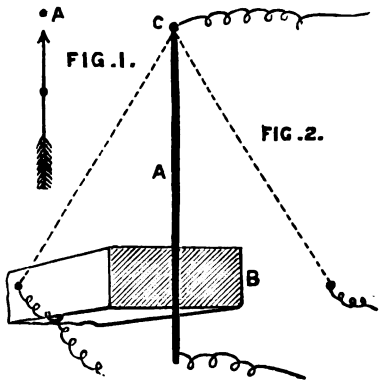
This latter explanation appears to apply to all the continuous current machines now in general use.

The facts to which I shall now refer cannot apparently be explained by either the approach to and recession from the magnet of a coil of wire, or by the increase or diminution of the number of "lines of force."

1st. If a current be passed through a wire, A, placed vertically (as in Fig. 1) in front of the needle of a compass, the needle is deflected to the right or left according to the direction of the current through the vertical wire.

2nd. Conversely, if a magnet, B (Fig. 2), be fixed, and a wire carrying the current be suspended freely in front of it from a point C, the wire will be deflected to the right or left according to the direction of the current or the polarity of the magnet.

The wire is not merely attracted or repelled, but it moves across the face of the magnet; in fact, if the point of suspension of the wire C be to the right or left of the magnet, and not vertically over it as shown, the wire is first attracted, and then repelled as it crosses the face.



3rd. Fig. 3 shows a fixed magnet, the face of which forms an endless path for the wire to travel over, the wire A being balanced immediately over the annular magnet B. The current is taken through the point on which the wire is pivoted, and out through a mercury trough into which its two ends dip.

The wire rotates rapidly one way or other according to the direction of the current through it.

These experiments may be as old as the hills, but they were new to me, and I mention them as appearing to constitute a complete chain of evidence in support of the theory that a conductor can be moved across the face of a magnet simply by the passage of a current through it, and that, conversely, a current may be generated by passing a conductor in front of a

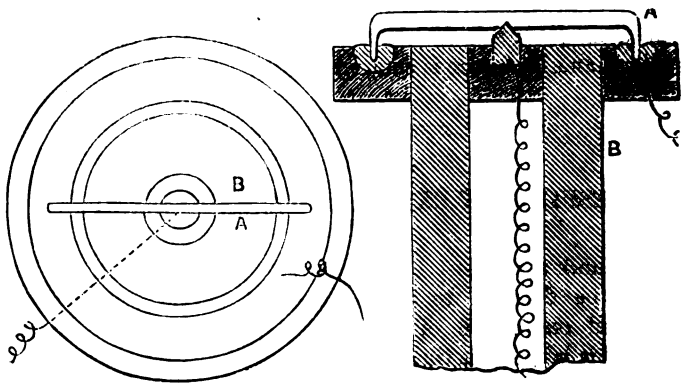


FIG. 3.

magnet without the necessity for any change in the magnetic field.

The lines of force *may* increase or diminish, but I should feel greatly obliged if some of your correspondents who appear to be on such intimate terms with them would explain how they do so, say, in Fig. 3.

I do not quite see why Mr. Voice finds it necessary to bring in the side wires of the Gramme ring to help to generate the current. It appears to me that if the armature and field magnet are sufficiently close together, the only effective, or, at any rate, by far the most effective part of the wire will be that which lies between the core and the field-magnet. Nor do I quite see how the action of all dynamos can be explained in this manner.

In the case of a dynamo with a pole armature, for instance,

Digitized by Google

the reversal of the polarity of the core would appear to account for the generation of the current.—Yours, &c.,

P. W. WILLANS.

Thames Ditton, March 10, 1884.

## WASTEFUL CURRENTS IN THE GRAMME RING.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: In reply to your correspondents who inquire how the production of wasteful currents in the Gramme ring can be explained in accordance with Faraday's "lines of force theory," allow me to refer to my letter in your issue of February 16. I there described an experiment in which a reversal of current occurred in a moving coil without any apparent cause; but so soon as the direction of Faraday's lines of force had been ascertained, by the process of actually moving a magnetic needle to and fro in the field, a diagram of this magnetic field and of the coil moving across it cleared up the whole mystery.

The action of a dynamo, with its main currents and its parasitic currents, its masses of iron more or less saturated with magnetism, and its numerous other complications, has not yet been thoroughly expounded. The difficulties of explanation do not, however, arise from errors made by Faraday or Maxwell, but from our imperfect knowledge of the facts. So soon as we can plot out on paper the direction a magnetic needle would take if placed in any part of the space in which the armature revolves, then and not till then are we in a position to apply the "lines of force theory" to the facts. Is there any instance known in which the "theory" thus tested has been proved erroneous? That it explains the action of the Gramme ring so far as wasteful currents and points of maximum effect are concerned was satisfactorily shown to those who heard Professor S. P. Thompson's lecture before the Society of Arts on February 28.

Your correspondents, "S. Thornton and W. R.," ask why on the "lines of force theory" the maximum effect is obtained at the points $\begin{matrix} N & N \\ S & S \end{matrix}$ on their diagram. But, as a matter of fact, those points are not the points of maximum effect; if the brushes were placed at those points the machine would be indeed wasteful. In practice the brushes are displaced by an angle, the magnitude of which depends upon the comparative saturation of the field magnets and of the armature ring. In fact the position of maximum total effect coincides, when the coils form one continuous wire, with the position of least action for each individual coil.

There are only two ways in which the "lines of force theory" can be upset. One is to demolish the reasoning by which the equation $V = i N$ has been established; the other is to discover some fact which is absolutely inconsistent with that equation.

Meantime the great practical experience which has been gained of late years has served to justify Faraday's suggestions, and to confirm Maxwell's exposition and expansion of them.—Yours, &c.,

W. M. MOORSOM.

Clevedon, March 11.

## SPIRAL TELEPHONE WIRE.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: As an extensive but totally unauthorised use has been made of the National Telephone Company's name by the Spiral Wire Syndicate, founded on the facts that the company had agreed to give the wire (as they like to give all new things) a trial, and that their manager at Dundee had been induced to certify that so far as he had observed the speaking by the spiral wire was clearer than by the older ones, I would ask space to detail the results of tests applied by me at Dundee on March 11 to one spiral wire and three ordinary ones, each four miles 197 yards long, extending from the company's Dundee Central Exchange to their Broughty Ferry Exchange.

These tests proved conclusively that in no sense whatever does the spiral wire possess any superiority over the ordinary ones.

The overhearing to and from the spiral wire was as pronounced as that between any of the others.

The speaking was good on all the wires, and the ticking of a watch was audible on all; but one of the older wires showed a decided advantage in respect to loudness of transmission over the spiral, while the other two were at least equal to it.

The conductivity and insulation of the wires were as follow:—

| | | ohms. | | ohms per mile. |
|---|---|---|---|---|

| No. 4. | ,, ,, | 251; | ,, | 92,000 |

Nos. 1, 2, and 3 were each composed partly of No. 18 silicium bronze, No. 20 phosphor bronze, and No. 14 galvanised iron. No. 4 was the spiral No. 13 steel wire, the only one the company have erected. The low and varied insulation is accounted for by the fact that the wires run along a densely-wooded road, and touch the trees (which are not allowed to be trimmed) here and there. But one of the old wires (No. 2) suffered more in this way than the spiral, and yet spoke just as well.

The speaking tests were conducted by three expert observers, listening at Dundee, who were kept ignorant of the wire upon which they were pronouncing judgment. The speaker, who was stationed at Broughty Ferry, was the same throughout, and the same instruments were used. The wires were tested in pairs. The mode of procedure was for the speaker to count from one to twenty without varying his voice or distance from the transmitter, and without knowing the wire he was speaking on. At the word "ten" a switch at Dundee suddenly changed the wires, without the knowledge of the observers. So the numerals 1 to 10 were heard on one wire, and 11 to 20 on another, an arrangement which enabled very slight variations in loudness between the first and second portions to be noticed. The results were as follow:—

All three observers agreed that No. 1 spoke better that No. 4.

All agreed that Nos. 2 and 4 were practically alike. Two thought No. 3 was slightly better than No. 4, while the third thought the reverse was the case. The difference, if any, was, however, of no practical importance.

One of the observers was Mr. Lumley, who satisfied himself that his original tests must have been erroneous. He appears to have tried the spiral against only one of the older lines, and the last results clearly indicate that there must have been a serious fault on this wire, or in some of its connections, at the time.

In justice to Mr. Lumley it should be known that he gave the certificate on the assurance that it was required for the private information of the syndicate, and was not intended for publication. It was granted without the knowledge of any of the company's other officials.—Yours, &c.,

A. R. BENNETT, Engineer, National Telephone Company (Limited).

Glasgow, March 12.

## WATCHMEN'S DETECTORS.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: Instead of thanking me for pointing out the palpable weak point in his new system, Mr. Fletcher thinks proper to reply in a manner very uncalled for.

His reply shows that he has recognised the oversight in the previous description, and patches up the weakness by saying "special care is taken in fixing the wires, and neither juvenile nor experienced electricians can get at them without detection." I do not wish to take advantage of the opportunity offered to me in the rather taunting language of Mr. Fletcher's letter.

The case I referred to where my apparatus was fitted "fourteen years ago" (but more correctly fifteen years) I repeat was the extensive varnish works of Messrs. Nobbs and Hoare, Cornwall-road, Blackfriars, which covers five acres, and contains property worth £500,000, the fire risk being almost the highest known. It is a gross misrepresentation for Mr. Fletcher to say he has *simplified* matters by his new system; but my letter was not written to criticise his new invention so much as to point out that other *very recent* manufactures exactly like mine were referred to by *The Electrician* as original.—Yours, &c.,

WALKER MOSELEY.

12, Queen's-road, St. John's Wood.

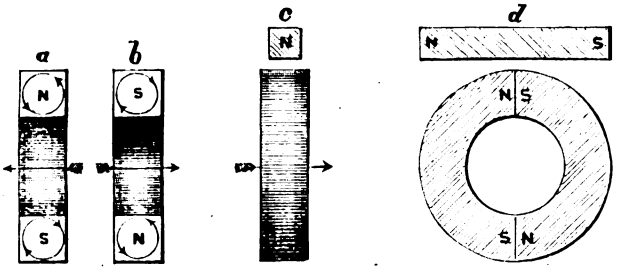
## ELEMENTARY NOTES ON ELECTRO-DYNAMIC INDUCTION.

BY DESMOND G. FITZ-GERALD.

The correspondence columns of *The Electrician* have recently brought into prominence the fact that some of the readers of this journal have the means, the time, the ability, and also the inclination, to perform careful experiments in connection with electro-dynamic induction. To them the following notes, which I have jotted down in somewhat crude form, and which are subject to correction from others or from myself, may possibly be suggestive. I also venture to think that they may be useful to a large class of students who are imperfectly acquainted with the most important fundamental facts relating to the above subject, and also to some, not belonging to that class, who have not yet obtained any very definite notions as to the magnetic polarity of a conductor conveying a current.

I have of course found no exception to the fundamental law that currents in the same direction attract, and currents in opposite directions repel; and cases such as (*g*) and (*j*) constitute, at most, only apparent exceptions to the law of Lenz, embodied in the statement that:—In all cases of electro-dynamic induction the induced currents oppose the motion which produces them.

(*a*) When an electromotive force acts initially to produce a current, a molecular action (stress) occurs in the conductor, tending to arrest the current without diminishing the expenditure of electrical energy which would accompany its passage, and at the same time producing a certain magnetic polarity in the conductor. (See figure below.) In this case work is done upon the conductor, and electrical energy is converted into magnetic potential energy or magnetic work.



(*b*) In the converse case, when the current ceases, the conductor recovers from its condition of stress, and loses its magnetic polarity, at the same time becoming traversed by a current in the same direction as that which originally produced this polarity. In this case work is done by the conductor, and magnetic energy becomes converted into electrical work.

(*c*) When a conductor ($w$) through which a current is passing is brought in proximity to another conductor ($w_1$) initially in its normal condition, a molecular action occurs in $w_1$, of a similar character to that which took place in $w$ whilst the conditions for conveying the current were being established. The latter conductor thus becomes traversed by a momentary current in the direction opposite to that of the current conveyed by $w$.

Two questions of great importance in molecular physics occur in relation to this case, in which work is done mechanically upon the system of conductors, since the inducing and induced currents are in opposite directions. First, is the current in $w$ momentarily augmented or diminished? Or, what is probably the same question in another form, is the magnetic energy stored in $w$ diminished or augmented? Secondly, does the conductor $w$ obtain any magnetic polarity that is permanent so long as the current passes in $w$? If this question be answered in the negative it would appear that the actual passage of a current, in addition to a certain molecular stress, is requisite for the production of a magnet. I will defer any answer I might venture to these two questions, since I have not been able to satisfy myself experimentally in regard to the points involved.

(*d*) In the case converse to the latter, when the conductor $w_1$ is removed from proximity to the conductor $w$, the former becomes traversed by a current in the same direction as that permanently flowing in the latter. Here, again, mechanical work is done upon the system of conductors, since the currents are in the same direction, and therefore exert a mutual attraction. And another question of great interest occurs. Is the electrical energy developed in the current traversing $w_1$ due wholly to this mechanical work, or partly to this and partly to magnetic energy stored in the conductor in the form of molecular stress? It is also of interest to observe that the conditions for conduction in the direction above specified have already been established in the conductor $w_1$, since this fact may account for the *suddenness* with which the electrical effect in this case (known under certain conditions as the *extra current*) occurs.

(*e*) When an electromotive force commences to act in a conductor (such as the coils of an electro-magnet) placed in proximity to a magnetic body, or when a current is caused to approach the latter, a molecular action which tends to prevent the passage of the current (during a period of time which is very considerable in comparison with that involved in case *c*) takes place both in the conductor and in the magnetic body. Although current disappears (as may be exhibited by the galvanometer) there is no diminution in the expenditure of electrical energy (represented, for instance, by zinc dissolved in a battery) which would normally occur during a period equal to that above mentioned. The extent to which this molecular action takes place determines what is called the "electro-magnetic inertia" of the system, or what is in reality the magnetic work done upon it. When, at the conclusion of the variable period, the current becomes constant, the magnetic body has obtained the maximum polarity of which it is susceptible under the given conditions, and has become a magnet, equivalent in its effects to a system of continuous circular currents in the same direction as the current traversing the conducting wire. In this case, energy—electrical, mechanical, or both—disappears and is converted into magnetic work.

(*f*) The case converse to the latter, when a current ceases, for instance, to flow through the coils of an electro-magnet, or when the coil traversed by the current is withdrawn from the magnetic core, is analogous to cases *b* and *d*. The induction effect is extraordinarily rapid and violent, the magnetic work suddenly taking the form of electrical energy, and the molecular condition of the conductor favouring the instantaneous passage of electricity in the given direction, viz., that of the original magnetising current.

(*g*) When two currents (voltaic or amperian) in the same direction are rapidly caused to approach each other, a molecular action occurs in both, the effect of which is momentarily to impede or arrest the passage of the currents, and to diminish or prevent the attraction between them. In this case there is no expenditure of mechanical energy; but electrical energy would appear to be converted into magnetic work. Thus the magnetic energy stored in the two conductors when in proximity would be greater than the sum of the magnetic energies when the conductors are at a distance.

(*h*) In the case converse to the latter, the two currents are momentarily augmented, without any additional expenditure of energy at the source of the electrical supply. In this case work must be done mechanically against current attraction, and the overcoming of this attraction results in a conversion of magnetic energy into electrical energy.

(*i*) When two currents (voltaic or amperian) in opposite directions are caused to approach each other, the currents are momentarily augmented. Here mechanical energy is expended in overcoming the repulsion between the currents, and this action results in a conversion of magnetic into electrical energy. Thus the magnetic energy stored in the two conductors when in close proximity is sensibly *nil* if the currents be equal, this fact being usually expressed by the statement that the electro-magnetic inertia of the system is *nil*.

(*j*). When two currents (voltaic or amperian) flowing in opposite directions are caused to recede from each other, they undergo a momentary diminution. Here there is no expenditure of mechanical energy in producing the recession; but it can be shown that a conversion of electrical energy into magnetic energy takes place.

Digitized by Google

It will be observed that, before a magnet can be generated, a current opposite in direction to that which virtually constitutes the magnet occurs in the magnetic system, and in conductors within its influence. In the interpretation of this fact, within the domain of molecular physics, is probably to be found the clue which will lead to an explanation of much that is obscure in regard to the intimate nature of magnetism, and to the relation between it and electricity.

The preceding diagram exhibits the magnetic polarity of a conducting wire conveying a current. A transverse slice of the conductor is supposed to be taken, and the central portion to be removed, so as to form a ring. The polarity of the two halves of this ring, which are exactly analogous to two horse-shoe magnets, is shown at *a* and *b*. The direction of the current traversing the conductor is indicated by the arrows. Fig. *c* shows the ring as reconstituted by reversing the position of *a* and applying it to *b*, the position taken up by a magnet suspended over the conductor being indicated at N. Fig. *d* is a front view of *c*, the current in the conductor being in the direction towards the observer.

It may here be noted—for the possible benefit of some students—that the direction of the amperian current in an electro-magnet is normally the same as that of the current in the coils; that (outside of ferro-magnetism at least) similar poles do not necessarily repel nor opposite poles attract; and that the current induced by the action of a magnet on a coil is never capable of reversing the polarity of the magnet.

## ON THE MEASUREMENT OF ELECTRIC CURRENTS.*

BY LORD RAYLEIGH, M.A., F.R.S.

Perhaps the simplest way of measuring a current of moderate intensity when once the electro-chemical equivalent of silver is known is to determine the quantity of metal thrown down by the current in a given time in a silver voltameter. According to Kohlrausch, the electro-chemical equivalent of

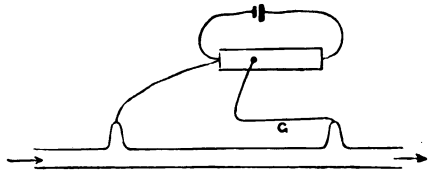


Fig. 1.

silver is in C.G.S. measure $1{\cdot}136 \times 10^{-2}$, and according to Mascart $1{\cdot}124 \times 10^{-2}$. Experiments conducted in the Cavendish Laboratory during the past year by a method of current weighing described in the British Association Report for 1882 have led to a lower number, viz., $1{\cdot}119 \times 10^{-2}$. At this rate the silver deposited per ampere per *hour* is 4·028 grams, and the method of measurement founded upon this number may be used with good effect when the strength of the current ranges from $\frac{1}{20}$ ampere to perhaps 4 amperes. It requires, however, a pretty good balance and some experience in chemical manipulation.

Another method which gives good results and requires only apparatus familiar to the electrician depends upon the use of a standard galvanic cell. The current from this cell is passed through a high resistance, such as 10,000 ohms, and a known fraction of the electromotive force is taken by touching this circuit at definite points. The current to be measured is caused to flow along a strip of sheet German silver, from which two tongues project. The difference of potential at these tongues is the product of the resistance included between them and of the current to be measured, and it is balanced by a fraction of the known electromotive force of the standard cell (Fig. 1). With a sensitive galvanometer the balance may be adjusted to about $\frac{1}{4000}$. The German silver strip must be large enough to avoid heating. The resistance between the tongues may be $\frac{1}{200}$ ohm, and may be determined by a method similar to that of Matthiessen and Hockin (Maxwell's "Electricity" § 352). The proportions above mentioned are suitable for the measurement of such currents as 10 amperes.

Another method, available with the strong currents which are now common, depends upon Faraday's discovery of the rotation of the plane of polarisation by magnetic force. Gordon found 15°* as the rotation due to the reversal of a current of four amperes circulating about 1,000 times round a column of bisulphide of carbon. With heavy glass, which is more convenient in ordinary use, the rotation is somewhat greater. With a coil of 100 windings we should obtain 15° with a current of 40 amperes; and this rotation may easily be tripled by causing the light to traverse the column three times, or, what is desirable with so strong a current, the thickness of the wire may be increased and the number of windings reduced. With the best optical arrangements the rotation can be determined to one or two minutes, but in an instrument intended for practical use such a degree of delicacy is not available. One difficulty arises from the depolarising properties of most specimens of heavy glass. Arrangements are in progress for a re-determination of the rotation in bisulphide of carbon.

## AURORÆ, MAGNETIC STORMS, AND SUN SPOTS.

BY G. W. VON TUNZELMANN, B.SC.

On the evening of Friday, the 7th November, 1882, I witnessed the finest aurora that I have ever seen in this country. Looking northwards from the upper deck of H.M.S. "Britannia," the whole surface of the heavens appeared to glow with a brilliant and continually changing rose-coloured light, streaked with green, which was reflected in the waters of the Dart, and brilliantly illuminated the hills among which the river winds. On the same day exceptionally fine auroræ were seen in different parts of England and Scotland, on the Continent of Europe, and in America, while in many places they were seen on several days preceding and following the 17th, on which day this wide-spread auroral display seems everywhere to have attained its height.

This remarkable display of the aurora at so many places at the same time was accompanied by two other phenomena, which though less generally noticeable, were of even greater interest to the scientific observer. Throughout the whole area in which the aurora was seen, it was found that the instruments at the telegraph stations were subjected to sudden and violent disturbances, owing to the passage of electric currents through the earth, and so great were these disturbances that in many cases telegraphic work was seriously hindered, or even completely stopped, and at some stations the currents attained sufficient strength to fuse parts of the apparatus. At the magnetic observatories similar disturbances were observed, indicating great and sudden changes in the earth's magnetism, and this magnetic storm culminated on the 17th, the same day on which the greatest auroral display took place. The other phenomenon to which we alluded was an exceptionally large spot upon the surface of the sun, and the sun-spot area attained its maximum about the same time that the magnetic storm was at its height.

The simultaneous occurrence of these three phenomena, each of remarkable magnitude, might in itself suggest the inquiry whether it were not something more than a mere coincidence. This inquiry had, however, been made long before, and we now have a mass of evidence to show that there is a close connection between them, so that the simultaneous occurrence in November, 1882, merely gives additional confirmation to a theory already advanced beyond the stage of hypothesis.

The first step which was made in the connection between

* [January, 1844. In a note recently communicated to the Royal Society (*Proceedings*, Nov. 15, 1883) Mr. Gordon points out that owing to an error in reduction, the number given by him for the value of Verdet's constant is twice as great as it should be. The rotations above mentioned must therefore be halved, a correction which diminishes materially the prospect of constructing a useful instrument upon this principle.]

Digitized by Google

these three phenomena was the establishment of a relation between auroral displays and magnetic disturbances, so that our attention must first be directed to the subject of the earth's magnetism.

It is well known that if a magnetised needle be suspended by its centre of gravity so that it can move freely about the point of suspension, it will assume a certain definite direction, depending upon its position on the earth's surface. This property of the magnetic needle is utilised in the mariner's compass, and Humboldt tells us that more than a thousand years before the Christian era, at the obscurely known epoch of the return of the Heraclidæ to the Peloponnesus, the Chinese already employed the figure of a man whose outstretched arm, containing a magnet, always pointing to the south, guided them across the trackless plains of Tartary.

If a magnetised needle be freely suspended by its centre of gravity it will not in general assume a horizontal position. In these latitudes, for instance, the north-seeking end of the needle, generally called its north pole, will point downwards to the earth, and the angle which it makes with the horizontal is called the magnetic dip. It is found that the north pole of the needle will point downwards with varying dip at all places which lie to the north of a curve, nearly coinciding with the equator, and which is called the magnetic equator. At all points upon this curve the needle assumes a horizontal position, and at places which lie to the south of it the south pole points downwards.

As we travel in either direction away from the magnetic equator the dip increases, until at two points, one about 29° from the north pole and the other about 14½° from the south pole, the needle would assume a vertical position. These two points are known as the magnetic poles. In the mariner's compass the needle is poised upon a vertical pivot, and in order that it may swing freely, it is necessary that its position should always be horizontal. This is effected by means of small weights which slide stiffly upon the needle, and can be adjusted to whatever position be required in order to make the needle assume a horizontal position. A magnetised needle, even when adjusted so as to be horizontal, does not in general point due north and south, and the angle which a needle so suspended makes with the geographical meridian is called the magnetic declination. The direction assumed by the needle is called the magnetic meridian. The direction of the magnetic force at any point is known when we know the dip, and the declination, and therefore the force, is completely determined if we also know its magnitude, which is called the magnetic intensity. These three quantities, the intensity, the dip, and the declination, are generally known as the magnetic elements, and not only do they vary from place to place on the earth's surface, but even at any one place they are subject to continual changes.

The first accurate observations on record of the changes in the earth's magnetism are the determinations of the declination in Paris. In the year 1541 the declination was easterly, and its amount was about 8°. This value gradually increased until the year 1580, when it had reached the value of 11° 30′, and then began to diminish until in 1660 the declination was zero, so that in that year the magnetic needle in Paris would point due north. In 1840 the westerly declination reached its maximum of about 23°, and then again began to diminish. Its value in Paris is now rather less than 17° to the west, and it is decreasing at an annual rate of about 9′ 5″.

The first reliable observations of dip were made in London in 1720, when its amount was 74° 42′. Since then it has continually diminished by about 2′ 5″ a year, its present value being about 32°.

These changes in the direction of the magnetic force are usually accompanied by changes in the intensity, but the latter have not been carefully observed until comparatively recently. It is found that these slow or secular changes are just what would be produced by a slow rotation of the magnetic poles round the earth's poles, and the period of rotation has been estimated at about 560 years; but it is clear that this must be very uncertain, as the observations have not as yet extended over the period of a single rotation. This secular variation in the earth's magnetism is of very great practical importance, as, although we know nothing of its cause, we are able, from the large number of observations continually made at different places, to predict some years in advance, and within fairly close limits, by how much the direction of the compass needle will deviate in any given year from true north and south throughout those parts of the globe most frequently traversed by shipping.

Besides this secular change in the earth's magnetic elements, there are other regular changes of shorter periods which are of the very greatest interest, for they show conclusively that the earth's magnetism is affected by its motion relative to the sun and moon. These smaller variations were first investigated by General Sabine, who discovered a daily and a yearly oscillation in the value of the declination. A number of other changes of different periods have since been discovered, nearly all of which have been shown to depend on the motions of the sun and moon relative to the earth. As the changes in the declination have been more thoroughly investigated than the changes in the other elements, and as the former are amply sufficient for our purpose, we shall confine our attention to them.

The first of the solar variations which we have to consider is the daily inequality discovered by Sabine, which is now known as the solar diurnal variation. Its period is one solar day, and the time at which the needle reaches the extremities of its swing is found to depend on the time of day at the place of observation, though this time is not the same throughout the year. We next come to a change with a period of about twenty-six days, discovered by J. Allan Broun at the magnetic observatory, erected in 1836, at Trevandrum, by the Rajah of Travancore, and re-discovered by Professor Hornstein by an investigation of the observations made at the magnetic observatories of Vienna and Prague. This period closely corresponds with the time of rotation of the sun relatively to the earth, Hornstein's value of twenty-six days eight hours for the magnetic period giving twenty-five days thirteen hours for the true time of the sun's rotation on its own axis, while from a long series of observations upon sun spots Schwabe gives twenty-five days five hours as the true time of rotation, which is a very close agreement when we consider the difficulty of determining the sun's time of rotation by the observations of the position of spots, owing to the motions of the spots themselves upon the surface of the sun. Another inequality of great interest was discovered by Dr. Lamont, who found that the daily variations attained a maximum at intervals of about eleven years. The great interest of this inequality consists in the fact, first remarked by General Sabine and afterwards independently discovered by Dr. Rudolph Wolf, of Zurich, that the greatest and least average of the daily variations happen at the same time as the maximum and minimum frequency of solar spots.

Other observers have fully confirmed the result that the maximum frequency of sun spots occurs at intervals whose average value is about eleven years, although they are somewhat irregular. They have also confirmed the correspondence between the magnetic and sun-spot periods. The times of maximum frequency of sun spots are also found to be the times at which magnetic storms, always accompanied by earth currents, are most frequent and most violent, and also the times at which the most remarkable auroral displays are seen.

The years 1860 and 1870 were both periods of maximum sun-spot frequency, and therefore the year 1882 had long been predicted as the time of the next maximum, and the year in which we were, therefore, to expect noteworthy magnetic storms and auroral displays. On September 1st, 1859, that is, very near to a period of maximum sun spot frequency, that indefatigable observer, Mr. Carrington, was observing a remarkably large group of spots, when he suddenly saw two intensely bright patches of white light break out within the spot area. In about five minutes the two patches had travelled over a space of about 35,000 miles, and then they disappeared from sight as two rapidly fading dots of white light. At the same time that this remarkable phenomenon was observed a great magnetic storm broke out, and telegraphic work was stopped in many places by the earth currents; at Philadelphia and at Washington the telegraph clerks received

Digitized by Google

severe electric shocks, while at a Norwegian station the telegraph apparatus was set on fire. At the same time extensive auroral displays were seen in both hemispheres. At the end of 1870 and the beginning of 1871, at the time of the next sun spot maximum, specially fine auroræ were again seen, and for the year 1882 the phenomena of November have verified the theoretical predictions in a most striking manner.

We must finally notice a daily variation which has been shown to be connected with the moon's motion with regard to the earth, and is therefore called the lunar diurnal variation. Observations made at various observatories, among others Greenwich, Lisbon, and Trevandrum, show that this daily variation has two maxima and two minima values in each lunar month of about 29½ days. Mr. Broun's observations at Trevandrum show that the maxima of the lunar, like those of the solar diurnal variation, occur at the times of maximum sun spot frequency, and the observations at Greenwich give the same result, and show that the changes in the moon's effect upon the needle are closely connected with the changes in the sun's effect. The examination of the Greenwich observations led Sir George Airy to suppose that the moon's magnetic action is itself due to that of the sun, and that therefore any alteration in the sun's magnetic power will make itself felt, not only directly on the earth's magnetism, but also indirectly through the change which it would cause in the magnetic action of the moon. The connection between the solar and lunar daily variations obviously affords good grounds for this hypothesis, and the fact that the daily lunar variation attains its maximum twice in the month of 29½ days gives additional evidence in support of this view, for this period of 29½ days, or the synodic lunar month, is the interval between two consecutive full moons. Now, full moon occurs when the moon is on the side of the earth opposite to the sun, so that supposing, for simplicity, the orbits of the earth and of the moon to lie exactly, instead of nearly, in the same place, the sun, earth, and moon will always be in the same relative positions at intervals of about 29½ days. Now, owing to the onward motion of the earth in its orbit round the sun, this interval is longer than the time taken by the moon to make a complete revolution round the earth, which it does in about 27⅓ days. It is evident, therefore, that if the moons' magnetic action were independent of the sun, its period would be related to the interval of 27⅓ days, and not to that of 29½ days.

(TO BE CONTINUED.)

## ON AN EXPLANATION OF HALL'S PHENOMENON.*

BY SHELFORD BIDWELL, M.A., LL.B.

Mr. E. H. Hall's papers giving a full account of his well-known discovery are printed in the *Philosophical Magazine* for March, 1880, November 1880, September 1881, and May 1883. His original experiment was as follows:—A strip of gold leaf was cemented to a plate of glass and placed between the poles of an electro-magnet, the plane of the glass being perpendicular to the magnetic lines of force. The current derived from a Bunsen cell was passed longitudinally through the gold, and, before the electro-magnet was excited, two equipotential points were found by trial near opposite edges of the gold-leaf, and about midway between the ends; when these points were connected with a galvanometer there was of course no deflection. A current from a powerful battery being passed through the coils of the magnet, it was found that a galvanometer deflection occurred, indicating a difference of potential between the two points, the direction of the current across the gold leaf being opposite to that in which the gold leaf itself would have moved across the lines of force had it been free to do so. On reversing the polarity of the magnet the direction of the transverse electromotive force was reversed; and when the magnet was demagnetised the two points reverted to their original equipotential condition.

Subsequent experiments showed that the direction of the effect differed according to the metal used. Thus with silver, tin, copper, brass, platinum, nickel, aluminium and magnesium, the direction of the transverse electromotive force was found to be the same as in the case of gold; with iron, cobalt and zinc the direction was reversed, and with lead there was no sensible effect in either direction.

Hall's results may be expressed by saying that the equipotential lines across the strip are rotated in a definite direction with respect to the lines of force. This effect was attributed by him to the direct action of the magnet on the current; and very great importance has been attached to the phenomenon in consequence of the opinion expressed by Professor Rowland and others that it is connected with the magnetic rotation of the plane of polarisation of light, and thus furnishes additional evidence of an intimate relation between light and electricity.

A number of experiments made by the author convinced him, however, that no direct action of the kind supposed was even produced, and he ultimately found that Hall's phenomenon might be completely explained by the joint action of mechanical strain and certain thermo-electric effects.

The strain is produced by electro-magnetic action. It will be convenient to refer to the metallic plate or strip (which for the purposes of this explanation may be assumed to be rectangular) as if it were an ordinary map, the two shorter sides being called respectively west and east, and the two longer north and south. Let the south pole of an electro-magnet be supposed to be beneath the strip, and let the strip be traversed by a current passing through it in a direction from west to east. Then the strip will tend to move across the lines of force in the direction from south to north. Since, however, it is not free to move bodily from its position, it will be strained, and the nature of the strain will be somewhat similar to that undergone by a horizontal beam of wood which is rigidly fixed at its two ends and supports a weight at the middle. Imagine the strip to be divided into two equal parts by a straight line joining the middle points of the west and east sides. Then in the upper or northern division the middle district will be stretched and the eastern and western districts will be compressed, while in the lower division the middle part will be compressed and the two ends will be stretched. If now a current is passing through the plate from west to east, the portion of the current which traverses the northern division will cross first from a district which is compressed to one which is stretched, and then from a district which is stretched to one which is compressed; while in the southern division the converse will be the case. And here the thermo-electric effects above referred to come into play.

Sir William Thomson, in 1856, announced the fact that a stretched copper wire is thermo-electrically positive to an unstretched wire of the same metal, while a stretched iron wire is negative to an unstretched iron wire. From this it might be inferred, as Sir William Thomson remarks, that a free copper wire is positive to a longitudinally compressed copper wire, and that a free iron wire is negative to a longitudinally compressed iron wire; and experiment shows this to be the case. *A fortiori*, therefore, a stretched copper wire is thermo-electrically positive to a compressed copper wire, and a stretched iron wire is negative to a compressed iron wire. If, therefore, a current is passed from a stretched portion of a wire to a compressed portion, heat will (according to the laws of the Peltier effect) be absorbed at the junction if the metal is copper, and will be developed at the junction if the metal is iron. In passing from compressed to stretched portions the converse effects will occur.

It follows from the above considerations that if the metal plate (which is subjected to a stress from south to north, and is traversed by a current from west to east) be of copper, heat will be developed in the western half of the northern division and absorbed in the eastern half; while heat will be absorbed in the western half of the southern division and developed in the eastern half. But the resistance of a metal increases with its temperature. The resistance of the north-western and south-eastern districts of the plate will therefore be greater, and that of the north-eastern and south-western districts smaller than before it was subjected to the stress; and an equipotential line through the centre of the plate, which would originally have been parallel to the west and east sides, will

now be inclined to them, being apparently rotated in a counter-clock-wise direction.

If the plate were of iron instead of copper the Peltier effects would clearly be reversed, and the equipotential line would be rotated in the opposite direction.

The peculiar thermo-electric effects of copper and iron discovered by Thomson are thus seen to be sufficient to account for Hall's phenomenon in the case of those metals. It became exceedingly interesting to ascertain whether the above explanation admitted of general application, and the author therefore proceeded to repeat Thomson's experiments upon all the metals mentioned by Hall. The results are given in the following table where those metals which in Hall's experiments behave like gold are distinguished as negative, and those which behave like iron as positive.

TABLE.

S means stretched. U means unstretched.

| Metals. | Forms used. | Direction of Current. | Hall's effect. |
|---|---|---|---|
| Copper | Wire and foil ; pure. | S. to U. | Negative. |
| Iron | Wire and sheet ; annealed. | U. to S. | Positive. |
| Brass | Wire, commercial. | S. to U. | Negative. |
| Zinc | Wire and foil. | U. to S. | Positive. |
| Nickel | Wire. | S. to U. | Negative. |
| Platinum | Wire and foil. | S. to U. | Negative. |
| Gold | Foil, purity 99·9 per cent. | S. to U. | Negative. |
| | *Wire, commercially pure.* | *U. to S.* | |
| | Jeweller's 18 ct. wire and sheet. | S. to U. | |
| | Jeweller's 15 ct. sheet. | S. to U. | |
| Silver | Wire and foil. | S. to U. | Negative. |
| *Aluminium* | *Wire and foil, pure.* | *U. to S.* | *Negative ?* |
| Cobalt | Rod : 8 mm. diameter. | U. to S. | Positive. |
| Magnesium | Ribbon. | S. to U. | Negative. |
| Tin | Foil. | S. to U. | Negative. |
| Lead | Foil (assay). | No current. | Nil. |

It will be seen that in every case excepting that of aluminium and one out of five specimens of gold there is perfect correspondence between the direction of the thermo-electric current and the sign of Hall's effect. With regard to the aluminium, a piece of the foil was mounted on glass and Hall's experiment performed with it. As was anticipated the sign of the "rotational coefficient" was found to be positive like that of iron, zinc, and cobalt. Either, therefore, Mr. Hall fell into some error or the aluminium with which he worked differed in some respect from that used by the author. The anomalous specimen of gold, being in the form of wire, could not be submitted to the same test. It probably contained some disturbing impurity.

It is submitted that the considerations and experiments above detailed render it abundantly evident that the phenomenon described by Mr. Hall involves no new law of nature, but is merely a consequence of certain thermo-electric effects which had been observed nearly thirty years ago.

## MAGNETIC POLARITY AND NEUTRALITY.*

BY PROFESSOR D. E. HUGHES, F.R.S.

In recent papers upon the Theory of Magnetism,† I gave the opinion, drawn from a long series of personal researches, that magnetism in iron and steel is entirely due to the inherent polarity of its molecules, the force of which could neither be destroyed nor augmented, and that, when we have evident magnetism the molecules rotate so as to have all their similar polarities in one direction. This opinion has long been held and demonstrated by the researches of Page, Marianini, Wertheim, Matteucci, De la Rive, Weber, Du Moncel, Wiedemann, Beetz, and Maxwell. The united demonstrations and reasonings of these *savants* leave but little doubt upon the minds of those acquainted with these researches that this view of the cause of evident magnetism is demonstrable, and no longer in the domain of assumption.

They, however, having no experimental data, adopted a theory of neutrality resting entirely upon hypothesis, and drawn from the ancient theory of magnetic fluids, where neutrality in iron was supposed to be the result of an intimate mixing of the two magnetic fluids. Coulomb, while accepting the molecular nature of magnetism, holds that the magnetic fluids are mixed in the molecule itself when neutral. Ampère assumes that the polarity is due to a circulating electric current ; he assumes also that after these currents have become symmetrical when polarity is evident, they become heterogeneous when the iron returns to an external neutral state. De La Rive, Weber, Wiedemann, &c., have all adopted this assumption of heterogeneous neutrality ; but it fails to explain why a neutral piece of iron is easily disturbed by external polarising forces, showing at first an apparent desire for external polarity, at the same time resisting this force, returning as with a spring towards neutrality, which it previously was ready to leave. There were in addition so many anomalies that I felt it necessary to make a series of researches upon the true nature of neutrality, the results of which I formulated in my theory of magnetism, viz., "that neutrality was a symmetrical arrangement or a balancing of polar forces, as in a closed circuit of mutual attractions." The series of researches which I now present bear unmistakable testimony to the truth of these views, showing the waves of opposite polarities which occur in iron, and that a symmetrical balancing of polar forces produces neutrality after each cessation of external polarity.

The instrument used for measurements* consists of a delicate silk fibre-suspended magnetic needle, always brought to its zero-mark by the influence of a large magnet at a distance, the angle of which gives the degree of force required to balance any magnetised body placed on the opposite side of the needle. It can also employ electro-magnetic effects by the use of two opposing coils on each side of the needle, balanced so that an electric current passing through the coils has no influence on the needle, except when a piece of iron or steel is placed inside one of the coils ; this again being balanced and measured by the large revolving magnet.

Before commencing my researches upon neutrality, I felt that it was necessary to observe the curves of magnetic penetration, whilst under the influence of its inducing cause. It is well known, however, from the researches of Gaugain, Du Moncel, and Jamin, that the magnetism does not penetrate to a very great depth with its full force, decreasing rapidly from the exterior to the interior. Most observations have been made by means of tubes of various thickness, introduced into each other. These, however, introduce an element of error, as, in separating them, they are necessarily drawn over each other. Jamin's method of dissolving the exterior of a steel magnet in diluted sulphuric acid gave results free from experimental error, but this could only be employed after the cessation of the inducing cause, the observations being really upon the permanent remaining magnetism.

The methods employed by myself consisted, first, in superposing twenty flat-iron strips, ½ millim. thick, 20 centims. long, and 3 centims. in width. These could be built up into a solid rod 1 centim. total thickness. Each piece was carefully selected and measured for its magnetic capacity, so that they should all be equal in value whilst under the influence of an inducing force, as well as their remaining magnetism when the influence ceased, the remaining magnetism being about a quarter of its capacity in the size and kind of iron employed.

These strips forming a compound bar were placed in contact with the poles of a strong permanent magnet, or they could be laid on one pole, the object being to polarise the lower bar only by contact, and observe the degree of penetration. The upper strip was carefully separated whilst the remainder was left under the polarising influence. We could thus separate each bar while under the influence without fear of reactions taking place between the separated bar and its companions. We had thus a bar or strip, separated while under the inducing influence, and, knowing its coefficient of remaining magnetism, we could estimate its full power when under the polarising influence. By this means the values were plotted graphically, giving curves of varying degrees, as the inducing force was changed, or the material of the strip from soft iron to hard steel. These curves were verified by a somewhat similar method, using a separate strip whose coefficient of remaining magnetism was known, and drawing this over the poles of a magnet, but separated from it by different degrees of thickness of iron.

These again were verified by an electro-magnetic method, in which a series of concentric tubes divided lengthwise was employed, so as to allow separation without friction, confirming the numerous curves obtained by the previous methods, showing that with a limited magnetising power acting upon homogeneous iron or steel, the penetration is inversely as the square of the distance from the inducing power, but with high powers the exterior soon arrives at its saturation, the distant layers rise in value, and also if the bar is not homogeneous there is a consequent deformation, owing to the comparative rigidity of its molecules.

In all cases, whatever the force employed, or nature of the iron or steel, there are no reversals of polarity in the interior, but a constant diminishing curve of penetration from the outside to the centre. This changes, however, the instant the exterior polarising force ceases, the different degrees of force between the external and internal react upon each other, producing the following results :—

*Internal Waves of Opposite Polarity.*

All varieties of iron and steel have a high magnetic capacity whilst under the influence of its inducing force, such as the electro-magnetic coils, or strong permanent magnets, but this power in a great measure disappears on the cessation of the inducing influence, a return more or less perfect towards neutrality being the result ; remaining magnetism is therefore a partial neutrality, more perfect in soft iron, where the molecules are in a greater state of freedom, than in comparatively rigid

cast steel. Our so-called permanent magnets are simply the remains of a far higher magnetic state, and it is already in most cases half-way down on its road to neutrality.

It is absolutely necessary in a theory of magnetism that we should know the cause of neutrality, for it is really the starting point to appreciate how polarity becomes evident. In my previous researches upon neutrality I used the induction balance, but in these I have employed more simple methods, which allow of repetition by the most simple means.

The first consists in forming compound bars of ordinary hoop iron, ½ millim. thick, and 30 or more centims. long, twenty or more of which could be superposed, bound together by a fine copper wire, and forming a rod of any desired thickness. They were magnetised by drawing over magnets of various powers, and the degree of approach to neutrality observed by the amount of its remaining magnetism. Now, on carefully separating them, there were invariably found violent curves of opposing magnetism, previously held bound by the closed circuit of mutual attractions.

The second method consists in superposing the divided concentric tubes, already mentioned, bound together by a fine copper wire, and magnetising them in the electro-magnetic coils of the measuring balance. By this means we could observe the charge or full magnetic capacity under the influence of an electric current, the remaining magnetism upon its cessation, and after taking out the tubular core, separate it, and observe the polarity of its successive internal layers. This method is objectionable, as the slightest rubbing of one tubular surface against another may alter the true value. The electro-magnetic method is, however, infinitely superior when observations are made on solid bars, or tubes of different degrees of thickness, to observe the influence of depth or thickness, in producing a perfect return to neutrality after cessation of the inducing effect of the coils.

The third method was a chemical one, somewhat similar to that employed by Jamin, except that as the object was to study the curves of neutrality, the bars were of annealed steel, highly magnetised in the coils, and afterwards reduced almost to a zero, by vibrating them, or beating them gently with a wooden mallet. We had by this means aided the molecules to follow their inclination, as they do in soft iron, for when a soft steel rod is in a state of vibration its molecules are comparatively free; but they rigidly retain the true curve of neutrality when not vibrated. We are thus enabled, by dissolving the exterior in various dilute acids, and by taking repeated observations, to draw graphically the waves of opposing polarities, which have produced external neutrality.

The curves obtained by the different methods are identical in form. The simplest and most accurate method is the first, as we can choose a hard variety of iron, such as ordinary hoop iron, and by slight vibrations or blows with a mallet, allow the molecules sufficient freedom to form their curve before separating, and as the material is sufficiently rigid not to be influenced by mere contact, or even frictional drawings, we have on each strip a perfect record of its state, and can thus analyse the internal state of a neutral compound bar.

If we take a compound bar of the hoop-iron, and draw the lower side over the south pole of a magnet, it will be found nearly neutral, or if not sufficiently so, we can reduce it by slight blows with a mallet. Suppose the united bar gives still a remaining magnetism of 18° on the magnetic balance, on separating the components and observing the same ends we find the lowest (or the bar which had touched the magnet) 150° north polarity; the next may be slightly north or zero; the rest will have varying degrees of south polarity, from 60° to 10°, the total of which exactly balances the north polarity of 150, less 18°, which we already observed as the remaining magnetism.

If we do not wish to approach a perfect neutrality, we should not vibrate the rods. In this case we may have 75° of remaining magnetism, and find on separating the strips that we have on lower strip 150° north, and the total opposing south polarity of the interior but 75° south, leaving the remaining 75° of north polarity first observed on the compound bar unbalanced.

The mutual reactions between the magnetic molecules in a solid bar are precisely similar to those between two or more separate bars, the reactions in the solid bar being more pronounced and complete than those obtained through a separation of air; the greater the separation the less the reaction, but in no case will the law of neutrality be changed.

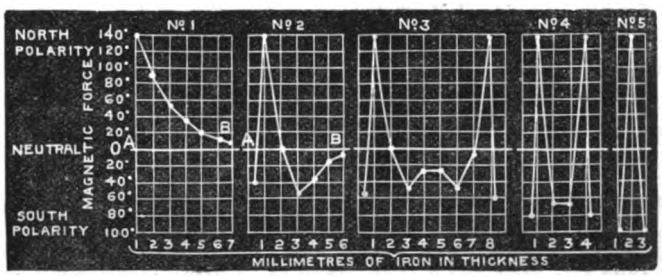
In homogeneous iron or steel, we have a well-defined curve, the distance of which can be calculated from observation upon the remaining magnetism, but if the interior is harder than the exterior, the inner portion will from its rigidity preserve its previous magnetism, reversing entirely the outer portions. This occurs also in small electro-magnets.

I have been enabled to prove this by the chemical method, employing either dilute sulphuric acid, acidulated bichromate of potass, or dilute nitric acid (1 pint acid to 5 water), the latter being far more rapid and equal in its action. The following experiment will show rapidly the influence of the outside reversal polarity. Let us take a soft steel wire 1 millim. diameter, 10 centims. long. Magnetise it in a coil, or by drawing over a strong permanent magnet, so that it has perhaps a remaining magnetism of 200°. If we vibrate this rod or give several blows from a mallet, we can reduce this to 25°; we have now almost perfect neutrality, having only a remaining magnetism of 25°, which remains a constant for years if not re-magnetised. Place this rod in dilute nitric acid, and in 15 minutes it will rise to 50°, or double its previous value, in one hour to 75°, and two or three hours to 100°, or four times its previous force; the increased force of 75° has been rendered evident by dissolving an equal opposing polarity of 75°, so that we have already found 75+75+25 =175°, or 87 per cent. of its highest force. This is so easily repeated with soft steels of all sizes and dimensions, that there can no longer be any doubt as to the existence of the outside reversed polarity. The experiment is more difficult to repeat with soft iron, as from the freedom of its molecules a fresh outside reversed curve is formed anew as the exterior is dissolved, the balancing curves reproducing themselves until we have almost entirely dissolved the iron; still with care, and iron not too soft, we can render evident all the neutral curves seen in steel.*

The curves obtained by the various methods are so numerous, each requiring more space than the limits of this paper will allow, that I am forced to give roughly the general outlines, as in Fig. 1. Suppose we take a compound bar of iron of eleven strips, and draw it over a permanent magnet, polarising its lower side only, its neutrality may be found nearly perfect, or 15° of remaining north polarity at the north end; now, on carefully separating these rods and observing the same ends, we have for the lower or the side which had been magnetised, 350° north; the following successively observed would give 10° south, 35° S., 55° S., 60° S., 50° S., 40° S., 22° S., 10° S., 6° S., 5° S.; here all the superposed bars are opposite in polarity to the exterior 350° north, the total south observed being 292, plus 30° south obtained from the exterior, by the coating of its lower face with the $\frac{1}{10}$ milim. of iron strip already mentioned. We are thus enabled to account for 323° south, and 350° north, leaving a remaining magnetism unaccounted for of 12°, which was doubtless disseminated on the surface of each bar on separation.

The above curves were obtained from the same polar (north) end of a compound bar of iron; the south or opposite end of the bar would give reversed curves to these. The curves are reductions to a similar force, but do not exhibit the perfection of the curves obtained on a larger scale.

No. 1 represents the typical curve of penetration of a bar of iron, whilst under the influence of an exterior polarising force, applied at A, or only at one side of a bar. When the force is applied to the whole of the exterior surface (as in a coil), A would represent the polar force on its surface, whilst B the interior. In all cases there would be a depression at the centre; great if the bar is thick, and comparatively small if the bar is thin. The curve rises with the exterior polarisation force, but in no case can a reversal ensue whilst under its influence. The instant, however, that it ceases, the higher magnetic power of the exterior layers reacts gradually and successively upon the weaker interior layers, rotating them through neutrality to a strong opposite polarity.



This is seen in No. 2, which represents exactly what takes place in No. 1 upon the cessation of the inducing influence. We notice that the first portion of the exterior has rotated to south polarity, followed by an intense north, but not of great density; its reaction, being more violent, rapidly rotates all the interior to a south polarity, gradually weakening in intensity as the distance increases from the inducing north polarity. The exterior, in fact, reacts upon its interior precisely as before the inducing exterior magnet reacted upon the whole. In No. 1 the south pole of the permanent magnet produced a continuous curve of north the instant this ceased, the north of the exterior produced an interior south, and if these are perfectly balanced, then and then only will the bar become neutral.

When both sides of a bar are polarised at the same time, then we have two similar curves to No. 2, as shown at No. 3, the diminishing curves of internal opposing polarity overlapping each other; the curve represents those obtained on bars 2 centims. in thickness. If the inducing force is great, the penetration is greater and more intense, reacting more violently, and the central depression of the opposing waves is less pronounced. If we keep the previous force and diminish the thickness of the bar, the two central waves cross each other, and at last, as in No. 4, we have only one wave; this occurs with bars of but 3 millims. thickness. We notice here that from a want of sufficient material in the centre of the iron it is constrained to force its central wave to a far higher degree, and that the exterior now also commences to be reacted upon more violently. Evidently the conditions are strained, and we shall see the result later. This want of sufficient material to form the internal opposing wave of polarity is shown when we reduce the thickness of the bar to 1 millim., the width being 3 centims., and the length 30 or more, as in all previous cases. Here there are no traces of an internal curve, the opposing polarity, as shown in No. 5, being entirely on the surface.

I have shown that we may clearly perceive this curve by dissolving its exterior in dilute nitric acid, but as I employed vibrations to reduce it to neutrality, this might give rise to objections on the score of mechanical reactions. To meet this objection, several strips of magnetised steel of various forms, but all ½ millim. in thickness, were reduced almost to neutrality by simply heating them to a dull red heat, allowing them to cool slowly. These gave remarkable results, proving that the vibrations caused by heat are similar in results to mechanical vibrations, and

* Thin flat steel, such as clock-springs, saw-blades, or ribbon steel, well annealed, are most suitable for this experiment. They may be of any width or length; the thickness may vary between ¼ and ¾ millim. I have found that strips of ½ millim. thick give the highest result.

Digitized by Google

I found that in most cases their external evident magnetism was increased 100 per cent. by an immersion of fifteen minutes, and 600 per cent. in one hour.

Interesting results can be obtained by this method, but if rapidity of chemical action is desired we must first remove the scale or oxide on the exterior by polishing with emery paper, or dissolve this first in acidulated bichromate of potass.

A perfect curve of these opposing polarities can be obtained by placing a glass vessel containing the steel and solvent in the balance itself, taking continual observations during its solution, and we may thus observe the gradual rise in force to a maximum, then its fall to zero, to an opposing polarity, completely verifying all previous observations.

Supposing the magnetised steel previous to heating gave 200° we should reduce it to 50° if heated to dull red, a bright red heat would probably reduce it to 20°; we should then start from an almost perfect neutrality to find, on dissolving its exterior (and allowing for the reversed polarity of the reversed portion), all its previous polarity.

Faraday remarked that the magnetic qualities of iron disappeared at yellow-red heat (1,050° C), reappearing gradually when cooled to red heat (700° C). I have found that if we heat the steel to yellow-red heat the whole previous structure disappears, and does not reappear on cooling. No satisfactory explanation, as far as I am aware, has been offered relative to the disappearance of the magnetic qualities of iron and steel at certain temperatures, but noticing that its internal structure is also changed, the following hypothesis may explain the phenomenon.

TABLE I.

| | Mag. cap. under influence of coil.* | Remaining magnetism on cessation of electric currents. |
|---|---|---|
| | deg. | deg. |
| 1. Tube of thin soft iron, 2c. dia., 20c. long, $\frac{1}{10}$mm. thick | 218 | 106 |
| 2. Similar size solid rod of soft iron | 960 | 29 |
| 3. Ditto cast steel, tempered | 458 | 18 |
| 4 Ditto bundle of 1mm. dia. soft iron wire | 1268 | 142 |
| 5. Ditto glass tube filled with iron filings | 160 | 15 |
| 6. Soft Swedish iron wire, 1mm. dia. | 455 | 105 |
| 7. Hard tempered cast-steel wire, 1mm. dia. | 49 | 16 |
| 8. Brass tube { Electro-plated with iron extremely thin { 3c. dia. 20c. long. | 0·95 | 0·94 |
| 9. Ditto { Electro-plated with iron to $\frac{1}{10}$mm. thick } Ditto | 231 | 109 |
| 10. Ditto Ditto 1mm. thick ... Ditto | 401 | 72 |
| 11. Ditto Ditto 1c. thick ..... 4c. dia. | 1075 | 35 |

* 1 Daniell element.

Assuming that increased heat increases molecular vibration, and that molecules would oscillate to a degree dangerous for the stability of any previous structure, a moment would arrive when the oscillations were so great that all structural formations disappear; and precisely at this instant there would be no external evidence of polarity, or magnetic quality, as the molecules would be oscillating through a range on both sides of external neutrality. On cooling (the previous structure having disappeared) they would satisfy their mutual attractions by the shortest path, forming probably, if perfectly free, a closed circuit of two, grouping themselves as a double molecule; but if a directing influence, such as a continuous current of electricity, was passed through the bar, then they would obey this influence, and in the latter case the closed magnetic circuit would be in concentric circles, as I have demonstrated in previous papers.

A similar effect is caused by mechanical vibrations. I have already shown that we increase the internal curves by gentle blows of a mallet, thus allowing the molecules sufficient freedom to follow their path, as in the case of red heat; but if we strike violently upon the end of the rod, the whole structure is broken down by the violent oscillations of its molecules, and the neutrality now resembles exactly that produced at yellow-red heat.

The theory of symmetrical neutrality which I have demonstrated requires that there should be a sufficient thickness in a bar of iron or steel in order to produce a symmetrical opposing polarity. Coulomb's theory of the neutrality taking place in the molecule itself requires no thickness except that of a molecule. Ampère's theory could become heterogeneous on the surface as easily as the interior, consequently thickness of a bar would, according to these theories, have no favourable result; but if the theory that I have advanced is true, thickness should have the greatest possible influence. An extremely thin strip or bar of iron should have an infinitely higher proportionate remaining magnetism from the want of interior reaction, whilst an extremely large solid bar should have infinitely less proportionate remaining magnetism. This at once allows us to test the truth of the theory by an independent method free from all experimental errors, as we may place in the coil of the magnetic balance bars of iron or steel of different degrees of thickness, observe their magnetic capacity whilst under the influence of an electric current, and the degree of remaining magnetism on its cessation, and note the extraordinary influence which thickness has in allowing space for the opposing waves of polarity to produce instantly a higher degree of neutrality than is possible without its aid.

The conditions of the experiments are really those of ordinary electro-magnets, the iron or steel under observation is simply at the time of observation a core of an electro-magnet.

Numerous experiments were made on this subject, all confirming the views advanced. A few examples will be sufficient to include them all, for if we place in the coil of the balance different thickness of the same diameter and length of iron or steel, we notice a marked rise in its exterior force or magnetic capacity while under the influence of the electric current, and upon its cessation an equally marked return to a more perfect neutrality with each increase of thickness. Table I. contains sufficient examples to show this clearly.

This Table gives the results and round cores; experiments, however, were also made with flat bars with like results, the form or length having no direct influence, as the reactions are transversal and localised from a point in the exterior to one in the interior.

Comparing No. 1 of the table (consisting of an extremely thin sheet-iron tube) with No. 2 (a solid bar of iron of exactly similar size), we have for the thin tube a remaining magnetism of 50 per cent. of its previous polar force, and in the solid bar we have only 3 per cent.; whilst in the solid bar, where the opposing waves of polarity could easily form and produce a near approach to neutrality, we find that its polar force under the influence of the coil is 400 per cent. greater than that of the thin tube.

Although, as well known, hard steel has a higher retaining power, still this can be reduced far below that of the soft thin iron if sufficient thickness is allowed in order to produce the internal reactions. This is shown in No. 3, where a solid 2 centims. diameter of hard cast steel has double the force of the thin soft iron under polarising influence, and its remaining magnetism only 4 per cent. of its previous force. This shows clearly that Jamin's views of the superiority of thin steel bars over thick where permanent magnetism is desired are fully confirmed, as in order to have raised the cast steel 2 centims. thick bar to a high remaining magnetism, we should have had to employ at least fifty times stronger inducing force than that necessary for the thin bars. The proportion of remaining magnetism in iron or steel to the inducing force is almost similar throughout the entire range up to saturation, where the remaining magnetism is no longer proportional to the inducing power, but remains a constant, no matter how high and powerful the influence excited. The molecules have simply then rotated to parallelism, and cannot rotate further without diminishing its force, and the sudden spring back to a partial neutrality is then the same for all forces above that of saturation. The proportion of remaining magnetism to that of its magnetic capacity under the influence of an inducing field is shown in Nos. 6 and 7, where iron and steel wires of similar diameter have not a wide difference, the remaining magnetism here being 25 per cent. for iron, and 33 per cent. for steel of its proportionate previous force.

The most conclusive experiments, however, will be seen in Nos. 8, 9, 10, and 11. No. 8 being a brass tube, coated with an exceedingly thin transparent coat of iron (I was unable to measure its thickness), a thin coating of iron was easily raised to its saturation by a feeble battery, from which point no increase of battery power had the slightest effect, giving always 0·95. The extraordinary effect of thinness was seen on taking off the inducing influence, no perceptible movement of the needle on the balance occurred, indicating that its retaining power was the same as its capacity, or 100 per cent. of retention; vibrations and hammering, which reduce a solid bar at once to perfect neutrality, had no effect. I have, however, marked it down as 0·94 as a limit of experimental error; if we assume only 80 per cent. of its previous force it is still sufficiently remarkable. At No. 9, where the brass was coated to a measurable thickness of $\frac{1}{6}$ millim., we already see a better return to neutrality, having now only 50 per cent. of proportionate remaining magnetism; at No. 10, where we have 1 millim. thickness, we have improved our neutrality by having only 20 per cent., and at No. 11 we have, by means of an increased thickness of 1 centim., almost completely allowed the balancing waves of opposite polarity perfect formation, the remaining magnetism now being only 3 per cent. of its proportional power; and if we even neglect the proportional power, we see that the 1 centim. bar has far less remaining magnetism than that of 1 or $\frac{1}{6}$ millim., whilst its magnetic capacity is far higher.

No. 4 shows that while bundles of wires have a higher remaining magnetism than solid (due to the want of homogeneity allowing perfect formation of the opposing waves), still from their increased surface exposed to the inducing effect they give a higher magnetic effect, the differential effect (as that employed in temporary electro-magnetic and induction coils) is greater, being here for solid bar 960 − 29 = 931, and for the bundles of iron wire 1,268 − 142 = 1,126 useful effect.*

The effect of thickness even upon finely-divided iron, such as filings, is shown in No. 5, where the remaining magnetism is only 9 per cent. against 50 per cent. as shown in No. 1, and we have precisely similar results with thin slices of iron filings as we do with the solid iron in sheets or tubes.

It would be difficult to explain these effects upon any hypothesis except that of molecular rotation. For, if we regard it as simply a case

* If we require a continuous magnetic effect, as in the field magnets of dynamo machines or small constant electro-magnets for extremely feeble electromotive force, solid cores or bundles of wire of large diameter should be employed, but as the time of charge and discharge increases with the diameter, it would be unsuitable for electro-magnets requiring rapid charges, such as those employed for telegraph relays, large electro-magnets requiring several seconds to charge them to saturation, while extremely small electro-magnets may be saturated in the $\frac{1}{1000}$ part of a second.

Digitized by Google

of magnetic induction, the stronger reacting upon the weaker, we fail to explain the perfect spiral form of the opposing waves, and above all, the reversal of the exterior, which was evidently the most strongly polarised, but if we suppose that the similar polarities of all the molecules have rotated, symmetrically pointing their north polarities to the evident north end of the bar, we have only to imagine a series of magnetic needles superposed with all their north polarities pointing in one direction brought and held there by the influence of a strong external magnet. If this influence was nearer the first needle than the last, we should have a slight spiral due to its diminishing effect, precisely as we notice in the curve in iron whilst under external influence. Now withdraw the exterior force, the needles would react against each other, and as they are free to move in all directions, there would be an increased spiral, the outside being reversed to its previous position, while the spiral would continue in the interior, reversing the larger portion of the needles until they all found a position of equilibrium, which would then represent neutrality.

If we had no frictional resistance to molecular rotation, we should obtain perfectly balanced curves in comparatively thin iron, but as this resistance is great and demonstrated by the loosening influence of mechanical vibrations, we require a certain depth of iron so that a complete curve shall be easily obtained with comparatively infinitely small motion of each molecule.

That inherent magnetic polarity is a quality of all matter, solid, liquid, gaseous, and the ether itself, varying only in degree and not in nature, seems demonstrated by a series of researches I have been making upon the mechanism employed in magnetic conduction through the atmosphere and Crookes's vacuum.

These researches are being made by means of the induction and magnetic balance. They prove that the atmosphere, and presumably the ether, as well as all liquids and gases, have their saturation point similar to iron, that the curve is the same as in perfect soft iron, and that the highest magnetic capacity of iron does not exceed that of the atmosphere by more than forty times; consequently we may fairly assume that the ether may be regarded as an extremely magnetic body, obeying the same laws as those of iron; and as I regard the symmetrical rotation of magnetic molecules as the cause of evident magnetism in iron, and as the difference in force between iron, copper, and ether is simply a differential one, I believe that the neutrality which appears in all paramagnetic and diamagnetic bodies, wherever the exciting influence is withdrawn, is formed by mutual molecular reactions producing closed circuits of mutual attractions as demonstrated in iron.

A line of force between a magnet and its armature is to me simply a line of molecular rotation; lines could neither be added nor subtracted, they could simply be rotated from a symmetrical neutrality to an equal symmetrical point of saturation.

In my paper upon the theory of magnetism, I showed that there were several molecular arrangements which produced external neutrality, the circular chain of molecules, when an electric current passes through an iron wire, a neutrality produced by an artificial superposition of a weaker contrary magnetism upon one more internal, and made the supposition that were it possible to have a piece of iron free from the influence of the earth, then (if there had been no previous magnetisation directing the structure) the molecules would short circuit their mutual attractions in the shortest path.

The experiments cited in this paper are of an extremely simple nature, and after being verified by independent observers. We can no longer doubt as to the cause of neutrality.

Whatever theory we adopt as an explanation of evident magnetism, it will be found that neutrality occurring after the cessation of an external inducing force upon a bar of iron or steel is the result of symmetrically opposed polar forces, producing apparent waves of opposite polarity, or reactions between the exterior and interior of a bar of iron.

## THE LANCASHIRE MAXIM-WESTON ELECTRIC COMPANY (LIMITED).

The first ordinary general meeting of this Company was held on Thursday, at the Cannon-street Hotel, the Earl De la Warr, in the chair.

Mr. T. R. COMYN (the secretary) read the notice convening the meeting, and the report of the directors was taken as read.

The CHAIRMAN said: Gentlemen, I believe you have the balance-sheet in your hands, and there are very few points in it to which I need call your attention. The directors certainly regret the balance-sheet is not so favourable as they hoped it would be, but there have been unforeseen circumstances which prevented its being so satisfactory as we could have wished. The loss has arisen in a great measure, as you are informed, through the Liverpool Corporation having unexpectedly stopped the extending of our system by refusing for nearly nine months to permit us to run more overhead wires, and this at a time when there were numerous applications for lighting. It was only in November last that the necessary permission was given to do so. Since that time I believe the Company has been doing a very considerable amount of work, and there is every reason to believe that it will be much further extended if the Company is enabled to continue to work, but there are certain difficulties in the way of the Company doing that work. Of course, a considerable amount of capital is necessary to do a large amount of work, and, unfortunately, the Company has not been able to put sufficient into into its work to make it so profitable a concern as we all should have wished. One of the chief reasons has been that the shareholders of the Company have not all paid up their shares, and this has involved the Company in certain legal expenses, and will involve further expenses if those legal proceedings are further continued. These are, I think, the chief reasons which have prevented the Company from doing work which they would otherwise have done. I believe the manager at Liverpool has had a great many offers of work which he would have undertaken if there had been capital to do so. You have been informed, gentlemen, that negotiations for a compromise with the shareholders in arrear has for some time been going on, and if these were completed and the money paid, the Company could well continue, we believe, without further contracts; but if some satisfactory arrangement is not made with regard to these shareholders, I certainly am of opinion that the Company cannot proceed with its work in a satisfactory manner. These will be questions for the shareholders to consider, and if the Company is to go on certainly measures will have to be taken to increase the capital of the Company; but if we reduce the amount, of course it is quite certain we shall not be able to carry on the Company with any advantage to the shareholders. Therefore, the whole question which now comes before the shareholders is this: whether it will be desirable to wind up this Company altogether, or to endeavour to make some arrangement with the parent company which will be satisfactory to the shareholders of this Company. I can only say it is the desire and wish of the directors to do what is best in the interest of the shareholders, and they very much regret the circumstances which have arisen, but over which they have no control. It is the first year of the Company's work, and considering the prospects held out to us for further employment it becomes a question for consideration whether some steps should not be taken with the view of preventing the Company altogether sinking away, either by handing it over to another company, or by endeavouring to place it in a more satisfactory position as regards the getting of more capital with which to work. I shall be very happy to answer, so far as I am able, any question which any gentleman present may wish to put, or to hear any opinion which may be expressed as to the best course to be pursued in the interest of the shareholders. The resolution I move is "That the accounts and balance-sheet and the report of the directors be, and they are, hereby received and adopted."

Mr. THOMAS WHITWORTH seconded the motion.

Mr. HUGH WATT pointed out the liability of £1,279 for directors' fees, and said that he did not think the shareholders would be disposed to agree to that.

The SOLICITOR said that if they passed the accounts the shareholders did not necessarily adopt that liability.

After some discussion the accounts, balance-sheet, and report were adopted without the admission of any liability on account of directors' fees.

Mr. HUGH WATT then gave a lengthy description of his various differences with the Board, and which culminated in his resignation. He also referred to the non-payment of the claims of the parent company.

The CHAIRMAN replied that with regard to the non-payment of the claims of the parent company he might say on behalf of the directors that every possible effort had been made by them to bring about a payment by obtaining payment from the defaulting shareholders. They quite admitted the claims of the parent company.

Mr. WHITWORTH said it would have been simply suicidal to have closed the Liverpool centre at the time Mr. Watt desired to do so. At that time they were under negotiations with the corporation which had resulted in full permission being given to continue the erection of overhead wires.

Mr. THOMPSON said that in Liverpool they were running 100 arc lamps from one centre. Their light had given the greatest satisfaction, and if they continued the Company there was a prospect of numerous further orders. In fact, they were overwhelmed with orders for lighting.

Messrs. Harling, Whinney, and Co. were then re-elected auditors.

The meeting was made special, and a resolution was passed to wind the Company up voluntarily, and Messrs. Whitworth and Roberts were appointed liquidators, with the understanding that they would open friendly negotiations with the Maxim-Weston Company with the view to the settlement of differences between the two companies, and in order, if possible, to arrange means to resuscitate or amalgamate the concern.

A vote of thanks to the chairman and directors terminated the proceedings.

## INDIA RUBBER, GUTTA PERCHA, AND TELEGRAPH WORKS COMPANY (LIMITED).

An extraordinary general meeting of this Company was held at the Cannon-street Hotel on the 12th inst., when the following resolution, which was passed at the extraordinary general meeting of the Company held on the 26th ult., was submitted for confirmation as a special resolution:-

"That the sanction of the India Rubber, Gutta Percha, and Telegraph Works Company (Limited) be given to the Bill introduced into the present Session of Parliament intituled 'An Act for defining or extending the powers of the India Rubber, Gutta Percha, and Telegraph Works Company (Limited), and for other purposes,' subject to such alterations, additions, and variations as Parliament may think fit to make therein."

The chair was taken by Mr. George Henderson (the chairman of the Company).

The SECRETARY (Mr. Wm. J. Tyler) having read the notice convening the meeting,

The CHAIRMAN formally moved the confirmation of the resolution.

Mr. S. W. SILVER seconded the motion, which was carried unanimously, and the proceedings then terminated.

ELECTRIC LIGHTING.—WANTED, on mutual and tentative terms, a quiet GAS or WATER ENGINE and DYNAMO, for a re-installation for restaurant, &c., wired and fitted for 80 incandescent lamps, situate under the Exchange of a large northern town; machinery in use and open to public view all day long. Successful installation certain to benefit manufacturers of engine and dynamo.—Address, D. B., 1, Lansdowne-place, Brunswick-square, London, W.C.

ELECTRICIAN, theoretical and practical, with experience in construction and management of Dynamos and Electric Lighting apparatus generally, good experimenter, with first-rate references, REQUIRES EMPLOYMENT; moderate salary.—"MHO," ELECTRICIAN Office, 1, Salisbury-court, Fleet-street.

Now ready, crown 8vo., price 5s. cloth.

THE PRINCIPLES and PRACTICE of ELECTRIC LIGHTING. By ALAN A. CAMPBELL SWINTON. With 54 Illustrations engraved on Wood.

This book is intended for the use of employers of the electric light, and the general scientific public.

London: LONGMANS, GREEN & Co.

## NOTES.

THE CABLES TO HOLLAND.—One cable between the Dutch and British coast has been repaired.

KHARTOUM.—A telegram from Cairo, dated Wednesday night, says that the wire near Khartoum has been cut.

THE UNITED TELEPHONE COMPANY'S BILL.—The Holborn Board of Works have resolved to petition against this Bill.

CABLES REPAIRED.—The cables between Antigua and Guadeloupe and between Maranham and Para are repaired.

EARTHQUAKE IN SOUTH AFRICA.—Colonial papers state that a slight shock of earthquake has been experienced at Kimberley.

NEW STAMP.—A new series of stamps available for postal and telegraphic purposes will be issued by the Post Office on and after April 1.

WEST COAST OF AMERICA TELEGRAPH COMPANY.—The gross earnings of this company for the month ending February 29th, 1884, were £4,000.

ELECTRIC LIGHTING IN PARIS.—Tenders are to be invited from a limited number of French electric lighting companies for supplying lamps to light the Halles Centrales.

POST OFFICE TELEGRAPHS.—The estimated revenue from the Post Office telegraphs for the approaching year is £1,734,589, or an increase of £16,516 over last year.

AWARD.—Messrs. Gerard and Co. have obtained a diploma of honour from the Fisheries Exhibition for their installation during the continuance of that exhibition some months ago.

THE TELEGRAPH IN WESTERN AUSTRALIA.—News from Australia says that considerable inconvenience has been occasioned owing to the continued interruptions in the telegraph between Albany and Adelaide.

REMOVAL.—Messrs. Woodhouse and Rawson, of 11, Queen Victoria-street, E.C., have removed the different branches of their works to West Kensington. Their works address now is Cadby Hall Works, Hammersmith-road, West Kensington, W.

EARTHQUAKE IN SPAIN.—A despatch from Alicante announces that a shock of earthquake lasting five seconds was felt there on Thursday, the 13th inst., causing slight damage. No one was injured. The shock was also felt in other parts of the province.

TELEGRAPHIC RECEIPTS IN FRANCE.—The receipts from telegraphs in France during January and February last amounted to 4,085,300f.; the receipts, according to the estimate in the Budget, should have been 4,389,000f., a difference of 303,700f., so says the *Journal Officiel*.

ANOTHER ELECTRICAL EXHIBITION.—Endeavours are being made to organise an exhibition of electrical appliances, &c., in Brussels. The Belgian Society of Electricians, the Town Council of Brussels, and the Union Syndicale of that town have all been asked to forward the project.

A NEW MICROPHONE.—A new microphone, invented by one Dembinski, whose name probably sufficiently indicates his nationality, has been tried at the Ministry of Posts and Telegraphs in Paris. Carbon is used in combination with some substance, the nature of which is kept secret.

ELECTRIC LIGHTING IN CAPE TOWN.—We understand that the new Houses of Parliament in Cape Town are to be lighted on the Edison system. Mr. Hortsek left this week to superintend the fitting up of the installation, particulars of which we shall hope to lay before our readers when complete.

THE LATE SIR WILLIAM SIEMENS.—An excellent engraving of the late Sir William Siemens has been published by the Universal Printing Company, of 280, High Holborn, W.C. The greatest care has evidently been taken to produce an accurate likeness, and we think the engraver has succeeded in doing this.

AGEING WINES.—The Electric Liquor Company of California professes to age and purify wines and other liquors by the electric current. Light clarets are treated, so it is said, in from three to six hours, whilst brandy requires sixty. This idea was talked about in France some little time ago, but does not appear to have made much progress as yet.

DETECTING INFERNAL MACHINES.—M. de Fonvielle has suggested the following method of detecting infernal machines:—All luggage to be placed on wooden tables supported by iron feet, but not nailed to them. A microphone to be placed on each of the tables, when any ticking or other noise proceeding from the luggage would at once become audible.

TELEGRAPH CLERKS' ERRORS.—In a recent note we referred to the decision of a German Court of Justice as to the responsibility of telegraph administrations for errors committed by their *employés*. In this case the Court found that the operator was liable and not the administration. The Supreme Court of Georgia, U.S.A., has, however, just given judgment against a telegraph company for an error committed by one of its operators.

NEW FIRM.—We are informed that Messrs. D. P. Menzies and W. M'Whirter, M.S.T.E. and E., have established themselves as electric light and consulting electrical engineers and electricians at 106, Elliot-street, Cranstonhill, Glasgow, under the style of Menzies and M'Whirter. During the last ten years Mr. M'Whirter has been manager and partner in the firm of Norman and Son, electric light engineers, Glasgow and Barrow-in-Furness.

EXPLOSION OF AN INCANDESCENT LAMP.—A correspondent who employs incandescent lamps in his shop writes as follows:—"The following curious circumstance occurred on Saturday night, the 15th inst. Perhaps some reader of *The Electrician* can explain the cause. Whilst the lights were running a Swan 50 candle-power lamp burst with a loud explosion, causing considerable alarm to customers who were in the shop at the time."

SOCIETY OF TELEGRAPH ENGINEERS.—The next meeting of the society will take place on the 27th inst., at the Institution of Civil Engineers, 25, Great George-street, when the following papers will be read:—"On the Proportion which ought to Subsist between the Size of Conductors and the Strength of Currents," by Professor George Forbes, F.R.S.E., member; "On the Relation which should Subsist between a Current of Electricity and the Conductor Employed to Convey it," by Thos. H. Blakesley, M.A., Assoc. M. Inst. C.E.

THE "GREAT EASTERN."—The leviathan may not become a coal hulk after all. News from New Orleans says that Captain James B. Eads, at present in London, has been requested by Mr. Burke, Director-General of the World's Exhibition, to ascertain upon what terms the steamer "Great Eastern" could be chartered to bring exhibits from Liverpool in October, and afterwards to serve as a floating hotel at the

Digitized by Google

Exhibition Wharf at New Orleans until the following June, when the vessel would return to Liverpool with a full cargo.

SAFETY LAMPS FOR MINES.—Sir Frederick Abel, Professor Sylvester Thompson, Professor Adams, and Mr. Burt, M.P., are making experiments every Saturday, at Woolwich, with the safety lamps sent in to compete for the prize of £500 offered by Mr. Ellis Lever. Between fifty and sixty lamps have been submitted to the adjudicators, and they are being tested under every condition that is likely to occur in coal mines. Some of the members of the Royal Commission on Accidents in Mines have also been present during the experiments.

PROTECTION OF SUBMARINE CABLES.—The International convention for the protection of submarine cables, the terms of which were settled at several meetings held in Paris recently, was signed at the Ministry of Foreign Affairs on the afternoon of Friday, 14th inst. All the plenipotentiaries assembled at the Quai d'Orsay, M. Jules Ferry, as Minister of Foreign Affairs, and M. Cochéry, Minister of the Postal and Telegraphic Department, being present to receive them and attach their signatures to the convention. Twenty-eight nationalities were represented.

ELECTRIC LIGHT FOR OBAN.—Mr. Grant, manager of the Edison and Swan United Company's Glasgow branch, writes with reference to our recent note under this heading (*The Electrician*, March 8) to explain that the statements in our note are accidentally misleading. Our remarks were based upon a report published in a local paper. It appears that the reporter got a "little mixed" over Mr. Grant's figures, and he is anxious that other aspiring seaports should not swallow all that he said at Oban as the "the truth, the whole truth, &c.," at least not that particular version given by the Scotch paper which reported his words.

WIRES IN PHILADELPHIA.—The Police and Fire-Alarm Telegraph Committee of the Philadelphia City Council have agreed to recommend the latter to repeal the ordinance regulating the tax on underground, overhead, and overground wires, and to substitute the following:—"That an annual license charge of 20dols. per running mile be made on all conduits, tubes, or pipes for electrical conductors not exceeding 2½in. in diameter; on those not exceeding 6in., 40dols.; on those not over 12in., 80dols.; and on all over 12in., 125dols. per mile, or part of a mile, made payable to the city of Philadelphia at the same time and under the same provisions, &c."

BOOKS RECEIVED.—"Elektrische Erscheinungen und Theorien," von John Tyndall, übertragen von J. V. Rosthorn; "Vortäge über Elektricität," von John Tyndall übertragen von J. V. Rosthorn; and "Die Physikalischen Grundsätze der Elektrischen Kraftübertragung," von Josef Popper; all published by Hartleben, of Vienna, Pest, and Leipzig. Also "The Theory of the Dynamo-electric Machine," by R. J. E. Clausius, translated and abstracted by Paget Higgs. Published by the Institution of Civil Engineers as a "Selected Paper." Our readers will remember that a translation of Prof. Clausius's masterly paper has already appeared in our columns. "The Principles and Practice of Electric Lighting," by Alan A. Campbell Swinton, published by Longmans and Co., of Paternoster-row.

UNDERGROUND TELEGRAPH WIRES.—The members of the Edinburgh Stock Exchange Association have forwarded a memorial to the Postmaster-General, pointing out the inconvenience and loss resulting to the memorialists and the community from the constantly recurring interruption of telegraphic communication caused by the frequent storms, and suggesting that at least the principal lines of communication throughout the country should be protected from atmospheric disturbance by wires being placed underground. It is not proposed that the underground system should supersede the present system. In ordinary circumstances it would act as an auxiliary, and in contingencies only as a substitute.

ELECTRIC LIGHTING IN WORKS.—The electric light has been introduced in the works of Messrs. Martin, Sons, and Co., of Lindley, near Huddersfield. The installation consists of one Crompton-Bürgin dynamo machine and eight Crompton-Crabbe arc lamps, requiring 14 amperes each, which light one half the burling room; one Crompton-Bürgin machine and twenty-nine 110-volt 20 candle-power Swan lamps for lighting the offices, and one machine and Crompton arc lamp requiring 28 amperes for the dye-house for the purpose of matching colours. The installation is pronounced very successful. It has been carried out by Mr. Wilson Hartnell, of Leeds, under the supervision of Francis Preston, Esq., C.E., of Kirkburton, who is acting as Mr. Hartnell's district agent.

INTERNATIONAL SOCIETY OF ELECTRICIANS.—The second monthly meeting of this society was held in Paris on the 5th inst., under the presidency of M. Georges Berger. It is said that more than 300 members were present. The chairman paid a hearty tribute to the services rendered by the late Comte du Moncel to electrical science; he also alluded to the loss sustained in the death of Louis Breguet. Lieutenant Hallez, of the French Navy, brought before the meeting some curious facts connected with abnormal deviations of the compass noticed on approaching the island of Madagascar. He promised to undertake a series of observations, and communicate the results to the society. M. Hospitalier read a communication on "Converters of Electrical Energy."

THE BENNETT-MACKAY CABLE.—The *Electrical World* says:—"The new Bennett-Mackay Cable Company will land one end of its cable on Cape Ann, Mass., and has bought land for this purpose at Cape Hedge, Long Beach. A cable station is to be erected at Rockport, the dimensions of which will be 60 by 45 feet and two stories high. The cable will be laid about two feet under ground for a distance of one and a quarter miles to the station in the town. A despatch from Ottawa, Can., of Feb. 15, states that the Bennett-Mackay Cable Company's Bill was passed on that day by the special committee of the Dominion House of Commons to which it was referred. Objection was taken to the extensive powers asked by the company to build new lines and amalgamate with existing lines. Amendments were made confining the company simply to the laying of cables and the constructing of land lines sufficient to enable them to make the necessary connections with the existing system."

MORE GLOWS.—Telegraphing from Paris, on Wednesday evening, the correspondent of the *Daily Telegraph* says:—"Something like a repetition of the splendid aerial phenomena which were witnessed in various parts of England and France towards the end of last year has recently been noticed here. M. Joubert describes the appearance of these new phenomena in a letter which he has sent to the Academy of Science. At four o'clock in the morning his attention was drawn to a flame of extraordinary brilliancy reflected on the mirror in his room. Looking in an easterly direction he saw the heavens from the horizon to a height of about 22 degrees illuminated in a magnificent manner. Objects around were seen distinctly, and in the atmosphere the partial mists and vapours were coloured with every conceivable variety of tint, from a deep blood red fringing the horizon in a limitless line to soft streaks of violet fading away towards the zenith. These splendid hues gra-

Digitized by Google

dually disappeared before the approach of dawn. M. Joubert does not venture on any explanation of the phenomena, and it is possible that they may have something to do with the exceptional heat of the weather experienced during the past week."

THE LATE DR. GINTL.—The *Journal Télégraphique* gives some account of the life of the late Dr. Gintl, who died a few weeks since. Our contemporary says:—"Born at Prague, in 1804, Dr. Gintl, after having passed through the various grades at the University in his native town, obtained a professorship, and for 15 years occupied the chair of physics, first at the Vienna University, then at Gratz. It was here that the Austrian Government sought him, when, in 1847, it endeavoured to introduce the electric telegraph, to obtain his co-operation in organising the new service. Shortly after he assumed the supreme management, which he maintained until 1857. Besides superintending the erection of the principal lines of the Austro-Hungarian telegraphs, Dr. Gintl made himself known as the inventor of telegraph apparatus, particularly the duplex system, which he was the first to originate and apply. His system was no doubt imperfect, but it was quite ready for those improvements which would have rendered it practicable had not the invention been in advance of the needs of the time. After resigning the management of the telegraphs, Dr. Gintl lived in retirement at Prague up to the time of his death, which occurred during the last few days of 1883. He was a member of the Academy of Sciences of Vienna as far back as 1849, and in 1863 he was made a member of the Society of Arts in London."

OVERHEAD WIRES—A SUGGESTION.—A discussion has apparently been raised on the overhead wire question in Australia. The correspondent of an Adelaide paper puts forward the following suggestion as an improvement on the present system of poles. He says:—"I propose to erect on each side of the street strong iron poles opposite each other, and from the top of each extend a light iron arch, made of T iron, resembling an archer's bow exactly, but with suitable ties from the string to the arch to strengthen the whole. Upon the top I would affix the insulators at suitable distances from each other to carry the wires, and from the string and from stays space would be available to meet the demand for years to come without erecting another post. Then from the centre of each let the electric light diffuse its brilliant rays, with no obstruction, but a fair division of light on both sides of the street. In the day time the appearance will be light and airy—novel no doubt, different from other places. So much the better if we can show the world an improved way to carry wires in the city. And at night the effect will be most brilliant, as there will be no limit to number and position of lamps to diffuse the light in all parts of the street. Now, says some thoughtful man, but how are you to get at the arches to affix the wires? Well, I have thought of that, and can meet the difficulty. The late superintendent of fire brigades, Mr. A. J. Baker, has had constructed a fire-escape that exactly meets the case—it is on wheels, but can be fixed to the ground immediately, and by turning a handle a platform can be raised to any desired height, which can carry two men and roll of wire, tools, &c. Now, with a sufficiently heavy bottom to give stability and security from toppling over a horse could be attached, and the whole affair drawn from arch to arch." The plan is scarcely novel, and we do not think it would answer; but that is no great reason why it should not be made public.

THE NEW CADIZ-CANARY ISLANDS CABLES.—The various works in connection with the Spanish National Submarine Telegraph Company's extensive system are being rapidly pushed forward, and on the 6th instant the subterranean cables connecting the landing places of the Gran Canaria-Santa Cruz and Gran Canaria-Lanzarote sections in the island of Gran Canaria with the office in Las Palmas—the capital of the Archipelago—were completed. The portion of land forming the port of Las Palmas is of curious formation, a low sandy isthmus connecting a rocky promontory, called the Isleta, with the main island. On the west side of this isthmus is the landing place of the Santa Cruz cable, and on the east, some considerable distance nearer to the town, is that for the Lanzarote section, which, owing to the "Dacia" having been occupied with other work, has not yet been laid. The two huts, distant apart about three-quarters of a mile, are connected by two india rubber core cables, one for the Santa Cruz section, and one spare. Between the Lanzarote hut and the office three cables are buried, consisting partly of india rubber core and partly of gutta percha, one each for the sea cables and one spare. The total distance from the Santa Cruz hut to the office is 3¼ miles. The average depth of the trench throughout is 5ft. 6in., and the cables rest in a cool, damp bed of earth. The cost of the whole work amounts to about 8½d. per yard, and the time in which it was executed—five weeks from start to finish, including unshipping and drumming off about nine miles of cable—must be considered as rapid in the extreme, especially when Spanish labour, rainy weather, and occasional patches of stony ground are taken into consideration. The tests give the following results:—Insulation, 1,020 megohms per statute mile; C.R., 9·5 ohms per mile. The whole work was carried out under the able direction of Mr. Richard Balkwill, and the above details show that he has good reason to be well satisfied with the results of his exertions. On the evening of the day that the ends of the cable were brought in the office was lighted for the first time by means of the Edison system of incandescent lighting.

DEVON AND CORNWALL ELECTRIC LIGHT COMPANY.—On the 19th inst., before Lords Justices Cotton, Bowen, and Fry, the Hon. F. W. Cadogan, a shareholder in this company, appealed against an order for winding up the company made by Mr. Justice Chitty on the 24th of April, 1883, on the petition of another shareholder. Mr. Cadogan had shortly after the presentation of the petition taken proceedings and obtained an order for the removal of his name from the company's register on the ground of misrepresentation in the prospectus, but the order was stayed pending the proceedings on the petition. He opposed the making of a winding-up order on the ground that he would be liable as a contributory, not having commenced proceedings and put an end to his liability as a shareholder before the petition for winding up. He contended that it would be inequitable to make the order under the circumstances. Mr. Waller, Q.C., and Mr. Proctor appeared for the appellant, and Mr. Ince, Q.C., Mr. Romer, Q.C., Mr. Whitehorne, Q.C., Mr. Warmington, Q.C., Mr. A. A. B. Terrell, and Mr. R. F. Norton for other parties.—Lord Justice Cotton, in delivering judgment, said that 37 out of 149 shareholders said they had been defrauded into taking shares, and that in consequence of the reduction in the capital of the company and for other reasons there was no reasonable prospect of the company going on, but it was dead as a commercial undertaking, In the opinion of his lordship, if even a small minority of the shareholders were desirous of going on, it would not be right for the Court to make a winding-up order, because the requisite majority might pass a resolution for voluntary liquidation. But in this case a meeting of the company had agreed that the company could not go

Digitized by Google

on, and there was not a single shareholder who wanted the company to go on with himself as a partner in the concern. The only persons who wanted it to go on were those who, like the appellant, wished the winding up to be stayed until they could sever their connection with the company. There was nothing unreasonable in making a winding-up order, because the order would prevent the proceeding taken by the appellant, after the presentation of the petition, from having any effect. The appellant had commenced his proceedings too late, and could not say the winding-up proceedings were inequitable. —Lord Justice Bowen and Fry concurred, and the appeal was dismissed with costs.

THE OTHER SIDE OF THE QUESTION.—A great deal has been said about the rights of Daniel Drawbaugh to be considered the—positively the—first inventor of the telephone. We will leave the *Electrical Review*, of New York, to give the other side of the question. Our contemporary says:—"The Drawbaugh boom doesn't seem to be much of a boom after all. When we first heard the Drawbaugh people talk we made up our mind that they hadn't much of a claim to anything, unless possibly it was to some new quality of brass; but, after listening to what they had to say, it became apparent that it were better to concede to them the telephone or any other thing they wished rather than be longer subjected to the repeated blast from their somewhat vociferous 'bazoo.' When we saw the picture of Daniel Drawbaugh in the *Graphic*, together with a very fulsome, not to say tiresome, description of him and his undertakings, we thought we discovered good evidence of the presence of a coloured gem'man on the fence. It was a delightful story. If it hadn't been for the pictures and drawings we should have taken it for a beautiful picture of backwoods life. Here was the little winding road that led past the churchyard, past the little white church and yet more diminutive school-house, winding along toward the great chain of mountains, purple tinted in the waning daylight. Everything was lovely in that little Pennsylvania town. The houses were white, the skies were blue, and the grass was green. But Mr. Daniel Drawbaugh was neither white, blue, nor green. He had been born white, but honest toil and a Pennsylvania sun had given him a swarthy complexion; the acquaintance of those famous jokers and jovial blades, the officers of the People's Telephone Company had prevented his being blue; and any one who had picked up Mr. Drawbaugh for a greenhorn discovered before he got through that he had made a serious mistake. To hear Mr. Drawbaugh tell his own story would bring the tears to the eyes of the most hardened wretch in the community, but the story when told by his friends of the so-called People's Telephone Company is better than Mark Twain's description of the discovery of America by Alexander Selkirk. Regardless of the statute which governs patents, Drawbaugh lays claim to an apparatus that had been in public use more than the allotted two years. His friends when asked why he did not apply for a patent years before when he claims to have invented the telephone, answer that he was too ignorant to know its value, and too poor to pay for a patent if he had known it."

IRIDIUM.—At the Cincinnati meeting of the American Institute of Mining Engineers, held recently, Dr. W. L. Dudley, of Cincinnati, described the process of fusing iridium and plating therewith according to the methods patented by Mr. John Holland, of Cleveland, Ohio, and now carried on by the American Iridium Co. To assist in working the metal Mr. Holland adds phosphorus, thus obtaining a phosphide of iridium. The process of making iridium pen points is as follows:—The metal is melted together with the necessary amount of phosphorus, poured upon a slab of iron, upon which a second slab is laid while the metal is solidifying. Thus large sheets, one sixty-fourth of an inch in thickness, are made, which are broken up, the pieces being soldered to a strip of brass. Then the drilling operation is begun. At first, the metal is countersunk with a diamond, it being found impossible to use anything but pure white diamond splint for this operation. For the drilling proper, a copper wire is used, placed in a drill making from 3,500 to 5,000 revolutions a minute, the wire being tapered down to a fine point with a file. Diamond-dust mixed with oil is put into the countersunk hole, and by jigging the drill up and down, the hole is put through. One man can drill about fifty points a day. The iridium phosphide is as hard as the ruby, and resists the action of acids. It has been applied for a large number of purposes. One of the most promising applications, besides that for pen-points, is for draw-plates for fine wire, in which case the perforated iridium plate is held by brass plates. It is used also in place of watch and clock jewels, for the knife-edges of scales, blow pipe tips, &c. The phosphorus may be removed by fusing with lime, by imbedding the phosphide in lime, and heating it to whiteness. The last traces are taken out by putting it into a lime crucible in an electric furnace. The dephosphorised metal is used chiefly for electrical purposes, for the contact points in telegraphic instruments. Experiments have also been made to test the value of iridium for electric arc-light points. It was found that it would do for the negative but not for the positive pole. It is necessary, however, that the positive pole shall not strike the iridium point, because the intense current makes it soft, so that pounding deforms it. Trials with electroplating have been fairly successful. It appears to be now a question of manipulation, so that iridium plating will probably come into use for certain purposes. The solution must be slightly acid. In order to prepare the salt for the iridium solution, a mixture of the metal and common salt is exposed to a low red heat in a muffle into which chlorine is conducted. The iridium phosphide is capable of alloying with iron, silver, and gold. An alloy of copper and iridium has been employed as metal for boxes.

INFLUENCE OF GALVANIC POLARISATION ON FRICTION.—In a recent issue of the *Annalen der Physik und Chemie*, Herr K. Waitz has an article on this subject, of which the following abstract appears in the *Journal* of the Chemical Society for February:—"In 1874 Edison noticed that the friction between a metallic and a porous plate moistened with some conducting liquid was diminished when an electric current was sent through this combination from the porous to the metallic plate. Further changes in the friction are produced by variations in the intensity of the current. This fact has been practically applied in the construction of telephones and electro-motographs. In this memoir the phenomenon is more completely investigated. The apparatus consists in the main of a clay cylinder filled with acidulated water, and enclosed within a glass vessel filled with water of the same concentration. A platinum foil is introduced into the inner, and a strip of glass in the outer vessel, on which a small platinum foil is stretched; this latter is connected with a mechanical arrangement whereby the platinum foil on the glass strip can be pressed against the clay cylinder with various degrees of pressure. The whole arrangement is enclosed in circuit with two Daniell cells, a metallic arrangement to measure the degree of pressure, and a rheostat to vary the intensity of the current. In many experiments it was found that the friction between the platinum and the porous cell is materially

Digitized by Google

diminished when the intensity of the current is sufficient to decompose the acidulated water. As the contact of the platinum and the clay was not found to be sufficiently perfect, a polished glass cylinder was substituted. The alteration of friction between glass and various metals, platinum, palladium, gold, and nickel, introduced into such solutions as sulphuric acid, potash, and soda, and potassium ferrocyanide was carefully examined; in the original memoir extensive tables are given of the results obtained in the course of the investigation. As a general result it may be stated that there is a diminution of resistance when the metallic plate is the anode, but an increase when the plate is the cathode, and the intensity insufficient to decompose the electrolytic liquid. This latter fact is contrary to the experience of Koch, who found no alteration in the case of the cathode. As the diminution of resistance appears only when bubbles of gas appear at the surface of the plate, it appears probable that the occlusion of the gas by the electrode is the cause of the phenomenon. Another hypothesis is that the formation of an electro double stratum, called forth by the polarisation on the surface of the electrodes, alters the external friction between the metallic surface and the glass on the one hand, and the glass and the liquid on the other. Further experiments will decide between these two hypotheses, but the writer inclines to the latter."

ELECTRICAL RESISTANCE OF INSULATORS.—In a recent issue of the *Comptes Rendus*, M. G. Foussereau described some experiments made to determine the resistance of certain insulators. We take the following abstract of the article from the *Journal of the Chemical Society* for March:—"The resistances were determined in the manner previously described by measuring the time required to charge a condenser at a given difference of potential across the particular substance. The resistance of porcelain varies with the temperature in the same manner as that of the more highly insulating varieties of glass; it is 751 at 60°, and 0·052 at 180°. (All the resistances except those of phosphorus are given in millions of megohms per cubic centimetre.) The resistance of sulphur, previously fused and then allowed to cool slowly in the prismatic condition, is 7·39 at 112·1°, and 3,930 at 69°; below the latter temperature the conductivity is inappreciable. When the same sulphur is allowed to remain at the ordinary temperature for some time, so that it devitrifies, its conductivity gradually increases; in one case the resistance after one day was 1,170 at 17°; after two days, 705 at 17°. Octahedral sulphur shows no trace of conductivity at the ordinary temperature, and the conductivity only becomes appreciable at about 80°. It would appear from these facts that sulphur has a higher resistance when crystalline. When sulphur melts, its resistance diminishes to one-fortieth its original amount. If the temperature is gradually raised from 114° to 150°, the resistance gradually diminishes as the temperature rises, and it varies between these limits in the ratio of 9 to 1. When the temperature rises to 160°, the sulphur becomes darker coloured and pasty, and its resistance increases. If the liquid is again cooled to the melting point, it retains a resistance higher than the original resistance, and the difference is greater the higher the temperature to which the sulphur has been heated, the longer it has been kept at this temperature, and the more quickly it has passed 155° in the process of cooling, this being about the temperature at which the inverse change takes place. By repeatedly heating the sulphur in this way to a high temperature, its original resistance at the melting point can be increased twelvefold. When sulphur is allowed to cool in the prismatic form and is then remelted, it shows a diminished resistance at the same temperatures. Similarly, when octahedral sulphur is repeatedly crystallised in the prismatic form, its resistance at 115° is gradually reduced to one-half. These results agree with Gernez' supposition that one variety of sulphur fully acquires the properties of another variety, only after repeated crystallisations. The resistance of carefully dried ordinary phosphorus is 84,000 megohms at 15°, and 15,600 megohms at 42°; it is of the same order of magnitude as that of liquid sulphur. The resistance of liquid phosphorus is 2·32 megohms at 25° (this is the temperature given in the original paper—apparently it should be 45°), and 0·34 megohm at 100°.

THE AXIAL MOTION OF THE EARTH.—A correspondent writes to the *Scientific American* as follows:—"In your issue of January 12, one of your correspondents, referring to the Foucault experiment with the pendulum, which is said to prove the axial motion of the earth, expressed a great desire to have the experiment repeated in Washington. I sincerely hope a committee of scientific men will take the matter up, and test the experiment thoroughly, and demonstrate beyond dispute the truth or falsity of it. Because, aside from the pendulum experiment, we have no direct palpable proof of the axial motion of the earth. Quite recently a number of scientific gentlemen in Great Britain and some of the public journals asserted the Foucault experiment false, coming to that conclusion after repeated tests of their own. In many cases the experiments have shown no change at all in the plane of oscillation of the pendulum; in others the alteration in the plane of vibration has been in the wrong direction, and very often the rate of variation has been altogether different to that which theory indicated. The *Liverpool Journal* states that a scientific gentleman in Dundee tried the pendulum experiment, and said that, as far as proving the axial motion of the earth was concerned, it was a gross delusion; but that it tends to the magnetic meridian he found to be a fact. The *Manchester Examiner* also reports an experiment by the Rev. H. H. Jones, F.R.A.S., in the Library Hall of the Manchester Athenæum, in which the rate of variation was entirely different to the accepted theory. Did space permit I could give particulars of several other experiments with like results. Now, in the face of all this, I agree with your correspondent that a thorough test of the Foucault experiment ought to be made in Washington to prove the truth or falsity of it. I would also suggest that two pendulums be used, one of metal the same as Foucault's, another of wooden rods pinned and glued together and a glass ball, or constructed of some perfect non-conductors of electric and magnetic currents. A cord would not answer, as the torsion might cause the pendulum to vibrate with a circular motion; the point of suspension ought also to be non-conducting, resting on a glass bearing. My idea for having one pendulum a perfect non-conductor is, that if a metal one is affected by electric currents or the magnetic meridian, the other would not be. Then if the two pendulums continued their oscillations in exactly the same plane, I think it would prove that electric or magnetic currents had no influence on the direction of their vibrations. In starting the pendulum great care is required to avoid giving any bias from the true plane of vibration. In the experiments referred to, a thread having a loop at one end was passed over the pointer on the under side of the ball, the pendulum drawn back and tied. When perfectly at rest the thread was burned apart, and the pendulum started on its course, the loop falling off. I would like to see immediate steps taken for a thorough practical test of this celebrated experiment."

## ELECTRO-CHEMISTRY.—INORGANIC.

BY DR. G. GORE, F.R.S.

(CONTINUED FROM PAGE 391.)

**Separation of Silver.**—Ag. Atomic weight = 108. A monad cation. Its commonest soluble salts are the nitrate, acetate, argento-potassic cyanide, ammonio-nitrate, and ammonio-chloride. Other soluble ones are ammonio carbonate, sodio hyposulphite, argento-potassic iodide, potassio-tartrate, and argento-potassic sulpho cyanide. Sulphate of silver is but slightly soluble. All the solutions of silver are readily decomposed by an electric current with deposition of metal upon the cathode, and in some cases with oxidation of the silver of the liquid at the anode, and formation of argentic peroxide. Nearly all the solutions of the salts of silver are reduced to metal by simple immersion in them of any of the base metals. Aluminium reduces the silver from an ammoniacal solution of argentic chromate (Watts's "Dictionary of Chemistry," Vol. VII., p. 54). According to Tribe, silver deposited by copper always contains copper, if the solution has absorbed air (*Chem. News*, Vol. XXIV., p. 76). Gold in contact with silver in a cold or hot acid or neutral solution of a salt of silver receives no deposit of silver (Raoult, *Jour. Chem. Soc.*, Vol. XI., p. 465).

**Formation of Silver Peroxide.**—F. Wöhler states that if a current from two Bunsen's cells is passed through a dilute solution of sodic sulphate or dilute sulphuric acid, by means of a silver anode, the latter becomes coated with argentic peroxide, due to the action of ozone. With a solution of potassic nitrate similarly treated, brown argentic oxide is formed; with one of potassic ferrocyanide the anode becomes coated with white amorphous argentic ferrocyanide, and with one of potassic bichromate it becomes covered with reddish-black crystallised argentic chromate (*Chem. News*, Vol. XVIII., p. 189). Brester states that by electrolysing melted caustic soda, with an anode of silver, the anode dissolved and silver was deposited on the platinum cathode, and that on cleansing the cathode with nitric acid, a residue of black powder of platinum was obtained (*Chem. News*, Vol. XVIII., p. 145). I have on various occasions noticed a similar residue after electrolysing melted argentic fluoride with platinum electrodes.

**Electrolysis of Argentic Nitrate.**—Ag. $NO_3$. Molecular weight = 170. According to Brester, hydrogen, evolved either by electrolysis, by the decomposition of steam by red-hot iron, or by zinc or iron in dilute sulphuric acid, reduces a solution of argentic nitrate, but not one of the sulphate; also, if a cathode of platinum, whilst being used in the electrolysis of dilute sulphuric acid, be instantly dipped into a solution of the nitrate, it sometimes reduces the silver and sometimes not (*Chem. News*, Vol. XVIII., p. 144). Russel observed that pure hydrogen reduces a solution of the nitrate to metal and nitrite (Watts's "Dictionary of Chemistry," Vol. VIII., Part II., p. 1,070).

Sodium amalgam decomposes a strong solution of argentic nitrate, and forms an amalgam of silver and mercury. Joule formed the same amalgam, but richer in silver, by depositing silver from the same solution into a cathode of mercury. According to W. C. Reid, thallium deposits silver from a solution of its nitrate by simple immersion (*Chem. News*, Vol. XII., p. 242). Metallic mercury, in an acidified and moderately strong solution of the same salt, forms a "silver tree" or "Arbor Dianæ." I observed that an aqueous solution of argentic nitrate yielded its metal by simple immersion to arsenic, antimony, bismuth, mercury, copper, brass, German silver, nickel, iron, lead, tin, cadmium, and zinc, but not to silver, gold, or platinum. In an alcoholic solution of the salt, antimony, bismuth, zinc, tin, copper, brass, and the alloys of silver with zinc, tin, or lead, deposited silver by simple immersion, but iron did not.

Electro-deposited nickel does not separate silver by simple immersion from a solution of argentic nitrate (J. Spiller, *Chem. News*, Vol. XXIV., p. 175). Aluminium after six hours' immersion begins to precipitate the silver, either from slightly acid or neutral solutions, whether concentrated or dilute (A. Cossa, Watts's "Dictionary of Chemistry," 2nd Supplement, p. 54). According to S. Kern, magnesium precipitates oxide of silver from an aqueous solution of argentic nitrate (*Chem. News*, Vol. XXXII., p. 309).

Fused argentic nitrate, when electrolysed by a separate current, yields silver at the cathode, and a large amount of oxygen at the anode.

**Formation of Argentic Peroxide.**—Ritter, in 1814, discovered that when a concentrated solution of argentic nitrate is electrolysed with two thick platinum wires as electrodes, peroxide of silver, $Ag_2O_2$, is deposited in crystals upon the anode, and metallic silver upon the cathode. Fischer states that these crystals always contain argentic nitrate (Watts's "Dictionary of Chemistry," Vol. V., p. 303). I have also found a nitrogen compound in them.

To deposit coherent silver from a solution of the nitrate requires the liquid to be weak and the current feeble. According to Luckow, the formation of peroxide of silver at the anode in a solution of argentic nitrate may be prevented by the addition of glycerine, milk sugar, or tartaric acid (*Chem. News*, Vol. XLII., p. 76).

Berthelot obtained sesquioxide of silver by the electrolysis of a 10 per cent. solution of argentic nitrate. It was in the form of large, thick, black, lamillar, striated, needles, of brilliant metallic lustre (*Jour. Chem. Soc.*, Vol. XXXVIII, 1880, p. 442).

**Electrolysis of Argentic Fluoride.**—Ag. F. Molecular weight = 127. I have observed that carbon and crystalline boron do not separate silver from fused argentic fluoride at a red heat, but that crystals of silicon thrown upon the melted salt become red hot, and burn vividly, producing silicic fluoride and separating silver; also that hydrogen separates silver from the semi-fluid salt. In an aqueous solution of the salt, crystals of boron did not separate silver, but crystals of silicon deposited slowly crystals of silver. Stannous fluoride in contact with platinum also separated silver from such a solution. I observed also that in a mixture of solutions of argentic fluoride, hydrofluoric, and nitric acids, crystals of silicon evolved spontaneously inflammable bubbles of silicide of hydrogen gas. (*Chem. News*, Vol. XX., p. 28, and XXIV., p. 291.)

I found the following to be the chemico-electric order of various elementary substances in fused argentic fluoride, the first being the most positive:—silver, platinum, charcoal of lignum vitæ, palladium, gold. And in a dilute aqueous solution of the salt, aluminium, magnesium, silicon, iridium, rhodium, and carbon of lignum vitæ, platinum, silver, palladium, tellurium, gold. (*Chem. News*, Vol. XXI., p. 28.)

In a number of experiments of electrolysing argentic fluoride in a fused state in a covered platinum vessel with platinum electrodes, with a current from six Smee's cells, conduction commenced before the salt had fused; and when the salt had become quite liquid, the conduction appeared to be as perfect as when the electrodes were united by a wire. No signs of genuine electrolysis were observable in either case. I also electrolysed the fused salt by a current from ten Smee's cells, with an anode of highly ignited charcoal of lignum vitæ. Very little conduction took place; the anode was, however, corroded, and evolved gas. (*Phil. Trans. Roy. Soc.*, 1870, p. 234. *Chem. News*, Vol. XXI., p. 28.)

I also electrolysed pure anhydrous hydrofluoric acid in a chilled state by means of a silver anode and a current from ten Smee's cells. Conduction was free, the anode corroded rapidly, and became covered, first with some black powder upon its edges, probably peroxide, and then with a grey powder, probably silver, which contained only a trace of soluble silver salt.

By electrolysing a saturated neutral aqueous solution of argentic fluoride with a small platinum anode, and a large platinum cathode, by a current from six Grove's cells, the conduction was free, but no gas or odour was evolved. A thick, hard, and strongly adherent crust of argentic peroxide formed upon the anode. By using a more dilute solution, a similar crust was formed, and gas was evolved from the anode. An aqueous solution of this very soluble salt was decomposed by an extremely feeble current with great ease. The deposition of silver, also, with this solution was so rapid that the depositing vessel soon became largely occupied by a loose, bulky

Digitized by Google

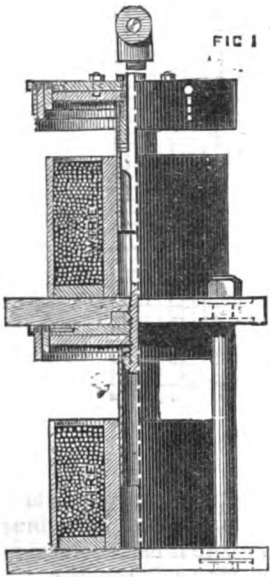
mass of fibrous crystals of silver, which soon metallically united the two electrodes if not frequently prevented.

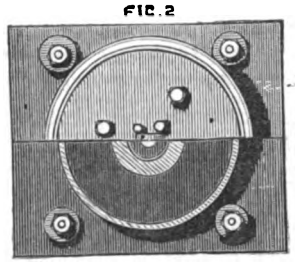
In the electrolysis of solutions of argentic fluoride containing free hydrofluoric acid, with silver anodes, I repeatedly observed that after the current has passed some time the anode becomes extremely brittle and porous, and its surface crumbles away, and falls as a powder to the bottom of the vessel, instead of dissolving smoothly, as with silver, in a solution of potassic cyanide. In order to test whether free fluorine diffused into the metal, I employed as an anode a pure silver tube, closed at the bottom, and communicating at the top with a pressure gauge. No signs of gas or of free fluorine, were, however, observed by means of this test, or by chemical ones.

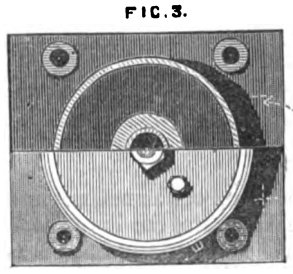
(TO BE CONTINUED.)

## ELECTRIC RAILWAY SIGNALS.

Amongst what we may now call the early practical uses of electricity, the most extensive applications for the purpose of



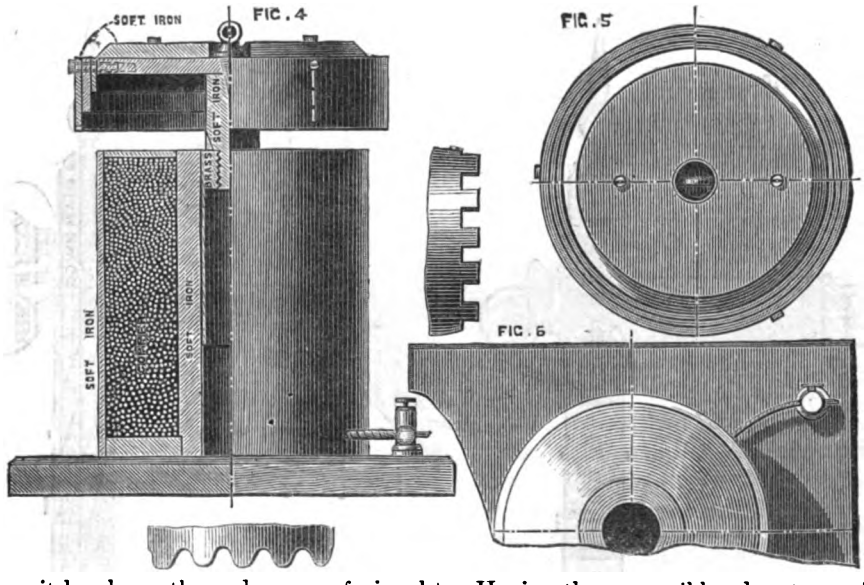




performing mechanical operations, as well as for telegraphy, were made along, and in the stations of, the railways of this kingdom. For some time it has been the endeavour of signal engineers to make much more direct application of electricity in the working of signals than now obtains with the current used almost solely for announcing train departures and similar information from station to station. A certain amount of interlocking is already effected by means of electro-magnets, but its practical employment is not accepted with universal favour.

One of the most salient advantages offered by the employment of electric currents for actually working the semaphore signals of railways, is that "distant" signals may be placed at any distance from a signal-box or station, while the present means of operating these signals limit their distance. A second advantage is the absolute safety which is secured by signals so worked, inasmuch as disarrangement of the signalling apparatus in any part from any cause allows the semaphore to fly to danger. Several other advantages accrue, including facility

of arrangement of signalling plant, simplicity of the apparatus and its application for direct interlocking.



Having these possible advantages in view has led Messrs. Currie and Timmis, of 2, Great George-street, Westminster, to devote their attention to the employment of modern electro-magnetic knowledge in devising the neccessary apparatus.

In this the essential element is Mr. Stanley Currie's long-pull magnet. No form of magnet hitherto brought out has had a sufficient range of strong pull to permit its use for moving semaphores. Half an inch of range only has been available, and even with this the strength of the pull has decreased approxi-

Digitized by Google

mately as the square root of the increase of distance between the magnet and the armature, and *vice versâ*, and consequently the velocity with which the armature of a powerful magnet came into contact with it was so high that the shocks to attachments made to it for effecting mechanical work, were so great as to make it impossible to use the magnet for such purposes. Moreover, the rapid decrease of magnetic attraction as the armature left the magnet, necessitated the use of great electromotive force and a powerful electro-magnet in order to obtain any considerable pull, even at half an inch, and this great power is nearly all wasted at the final part of the pull. These disadvantages are, however, obviated in the "Currie long-pull electro-magnet," because the magnetic attraction in it is much more evenly distributed over a long range, and, at the same time, a much stronger initial pull can be obtained at a greater distance than in any other electro-magnet of the same weight and with the same current. It exercises a practical working pull of several inches, and by the use of various sizes and shapes of the movable parts of the armature and magnet the pull can be graduated according to the requirements of any particular case. A very small current is required, and a small electromotive force, and consequently there is no danger in handling the wires when the magnet is in work.

This magnet we illustrate in two forms by Figs. 1 to 6. From these it will be seen that the single magnet, Figs. 4, 5, and 6, consists of a central soft iron tube, the lower end of which is attached to a soft iron plate, which at its periphery supports a larger soft iron tube, the annular space between the two being filled with covered wire. A brass plate covers the upper part of the magnet so made. The armature consists of a central core, the lower part of which is covered by a brass tube. At the top of the brass tube the core is made conical for a short distance, and above this it supports a soft iron disc, with a flanged periphery, of the section shown at Fig. 4. The outer part of this flange is adjustable as to the amount by which it projects downward from the disc, and it is, moreover, in some cases made with a serrated or wave-formed edge, as shown in detached fragments in the engraving, the object and the result of this being that the pull by the magnet is not suddenly increased as the disc nears the magnet head. It will be seen that the magnet and the short core act as a solenoid until the core has entered a considerable distance into the tube. This

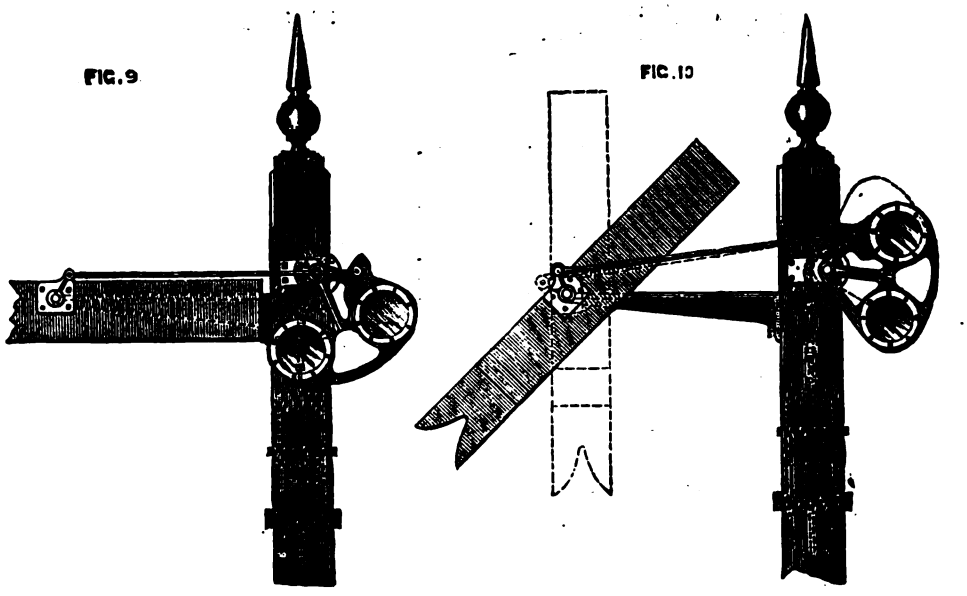
FIG. 7.



Digitized by Google

gives the first part of the pull ; and as the strength of the pull on the core is decreasing, owing to the core having approached the position of greatest solenoid effect, the disc head of the armature is nearing the magnet head, and the pull on it consequently increasing. Hence the approximately equal pull through a considerable range. Owing to the use of the encircling flange to the armature, a good deal of the effective pull just at contact is prevented by the loss of effect axially, consequent upon the diversion of the lines of force into a direction radial to the magnetic centre or normal to its axis and surface. Figs. 1 to 3 show the magnet as arranged in pairs, to obtain a double length of pull, as required, for working signals, when the semaphore is required to stand at the three positions of "line clear," "caution," and "danger." When the armature of the upper of the pair of magnets has reached its lowest point, the armature of the lower magnet has reached a position in which it has just begun to act, the spindle connecting the two being free to slide within the core of the upper armature, the range of one magnet being thus added to the other. This is sufficiently obvious from the engraving to render further explanation unnecessary.

The curves given at Fig. 7 (p. 440) show the variation of the pull of the magnet as the armature descends and the difference in that variation with the encircling armature ring in different positions.

In our engraving, Figs. 8, 9, 10, the magnet is illustrated as applied to a signal, with the semaphore balanced at mid-length. From these it will be seen that a box containing the magnet is at the side of the post opposite to that carrying the arm and spectacle. The spectacle forms the balance weight, or rather weight by which the semaphore is held at "danger" when the circuit is broken and the magnet not acting ; the semaphore is locked in that position against any forces other than the pull of the magnet upon its quadrant at the other end of the spectacle plate. Figs. 9 and 10 show the application of the modified form of the magnet, made, as already stated, with a view to holding the semaphore in either of the three positions, "line clear," "caution," or "danger."

Fig. 11 is a sketch of the arrangement of the signals and switches and point levers in the signal box in works of the Gloucester Waggon Company, by whom the signals have been made for the inventors. Three point levers of the usual kind are shown, and ten signal levers by the new system, with the accompanying electrical instruments. To describe the arrangement of the wires, contacts, and commutators employed in this signal-box, with the various connections, we must refer to the details shown at Figs. 12 and 13, and the diagram

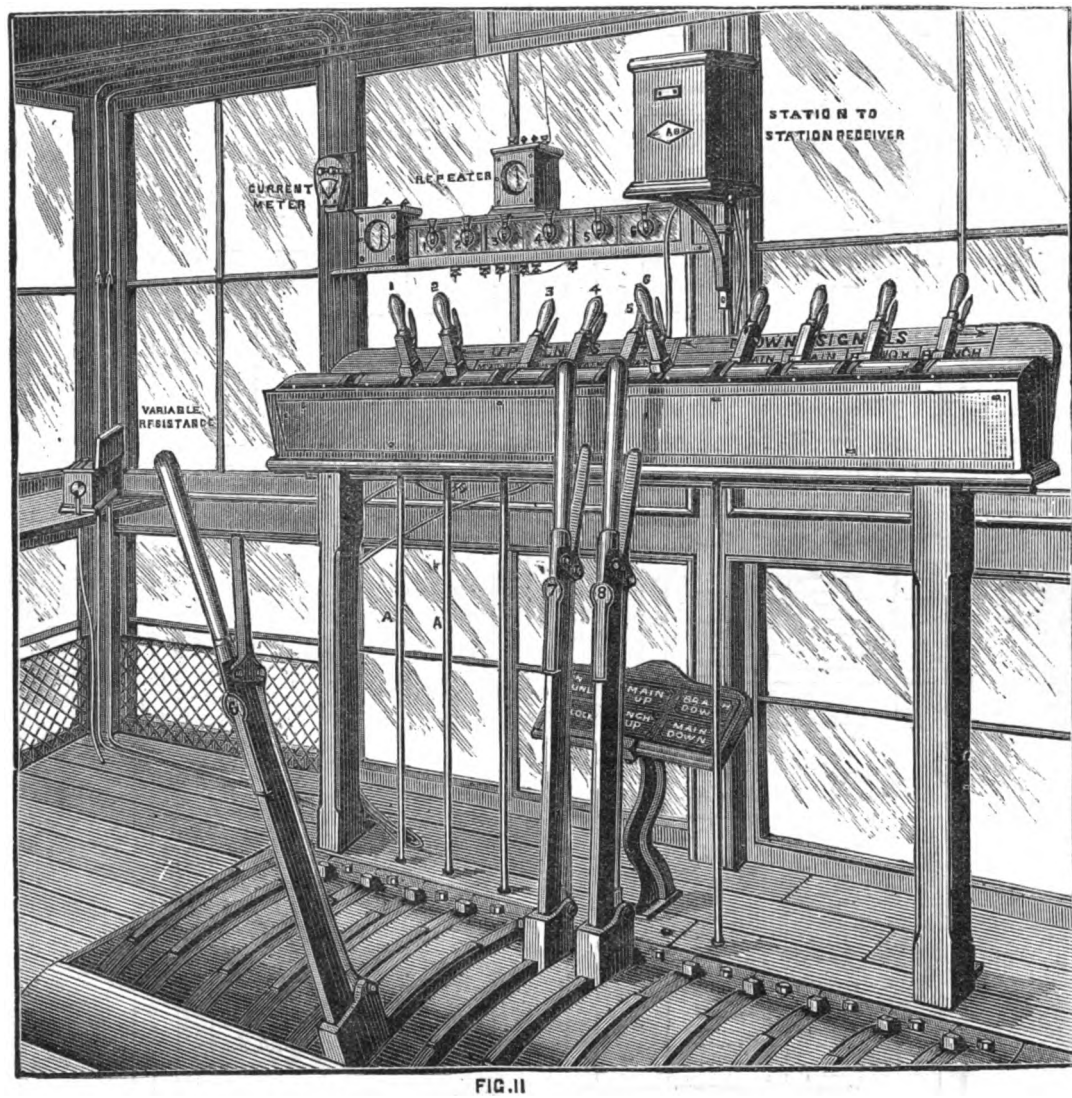


FIG. 11

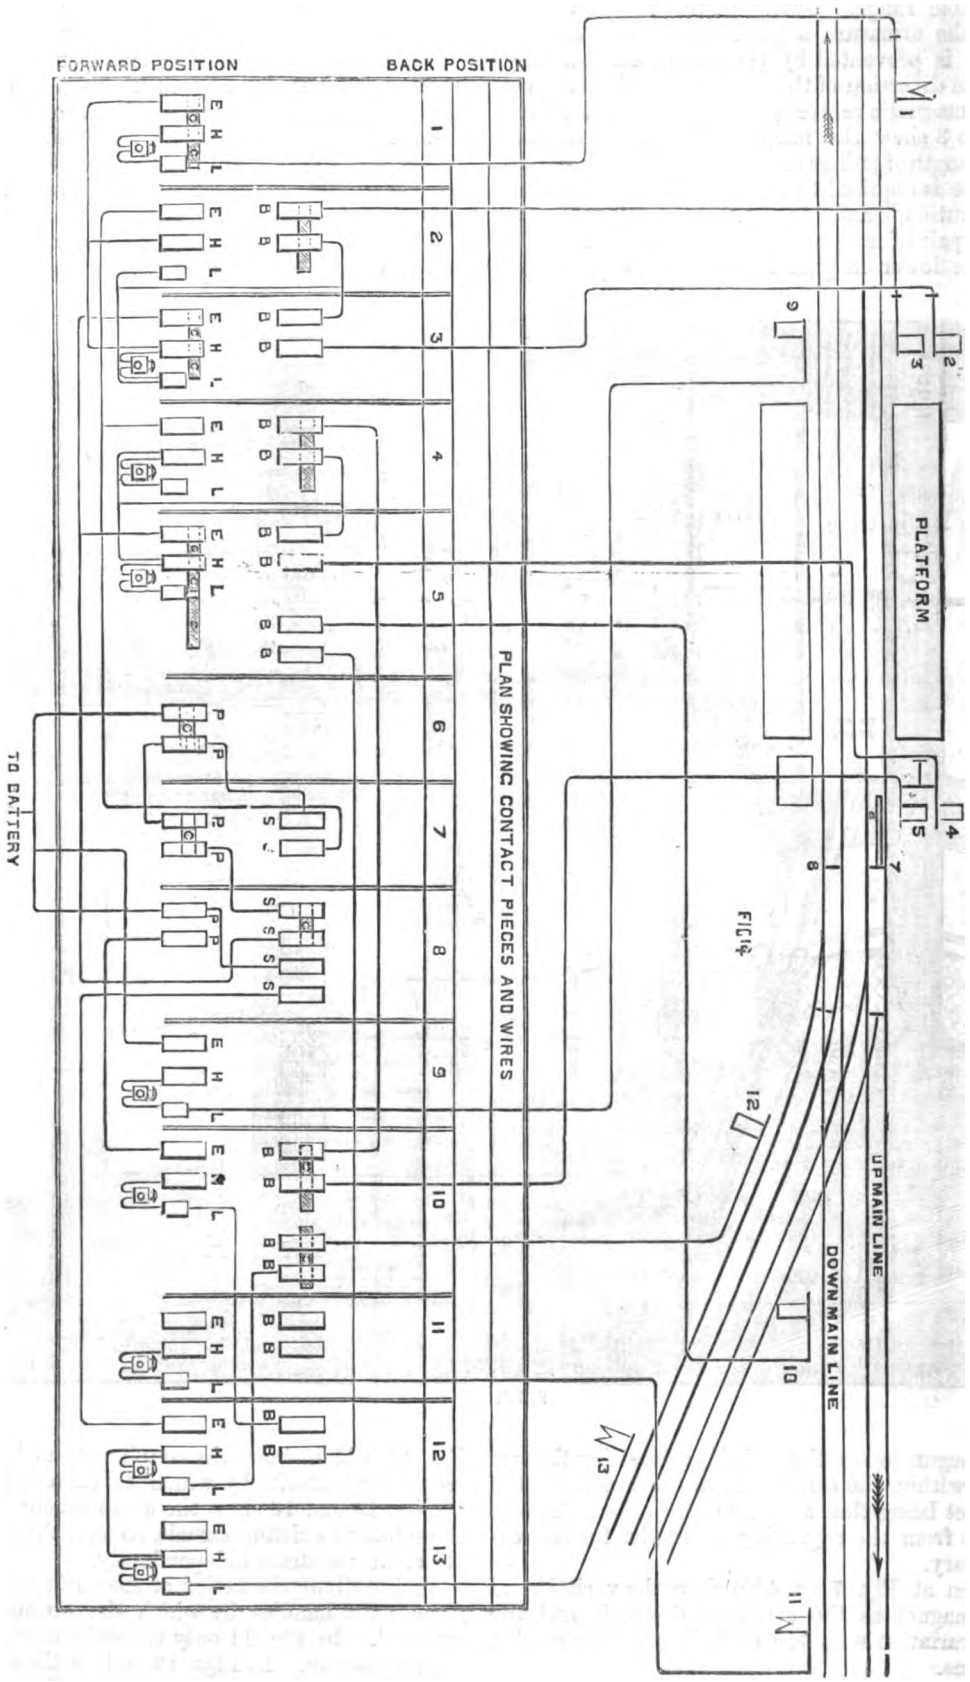
Fig. 14, which shows the coupling up of levers, resistances, and secondary batteries by which the current is supplied.

Figs. 15 and 16 show the arrangement by which the system is applied to existing signals, so that they may be worked by old or new systems independently.

In describing the action of the various parts we may at first refer to the handles by which the ordinary signal levers are replaced. In Fig. 11 only the switch levers, numbered 1 to 6, are coupled up. In Figs. 12 and 13 these small switch levers are shown to a larger scale, and the Swan lamps used as resistances are shown attached near the lever instead of in the position shown in Fig. 11. From Figs. 12 and 13 it will be seen that when the lever Y is in the position Z the contact piece C is not touching L, so that the current now going to the signal magnet must pass through the lamp into L. Only a very

Digitized by Google

small current is thus passing, this being the position of the lever when the armature is upon the magnet. When the lever is in the position X the current passes on for use in other of the magnets and the semaphore stands at danger. When the lever is pulled over to the position $Z^1$, the contact piece lever to take the position Z. The quadrant and spring also come into play when the handle is pushed beyond X. The Swan lamps not only act as resistances, but they show the signalman when the current is passing and all is working properly. When the armature of the magnet is pulled



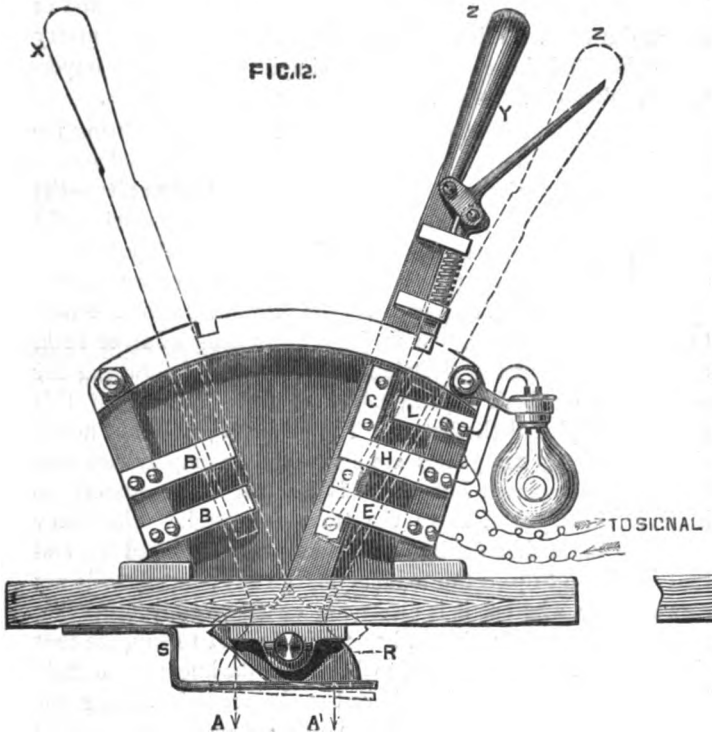
C being in contact with L, the full current passes to the signal magnet. This is required to start the magnet and pull the semaphore down. It is done momentarily, and the lever will not remain in this position unless purposely held, because the spring S pressing against the quadrant R causes the "home" and the signal is "free"—*i.e.*, "line clear," a contact switches on a small return resistance wire, between the magnet and the rail conveying the return current, which works a small magnet and tell-tale signal or "repeater" in the signal-box, and thus tells the signalman the position of the

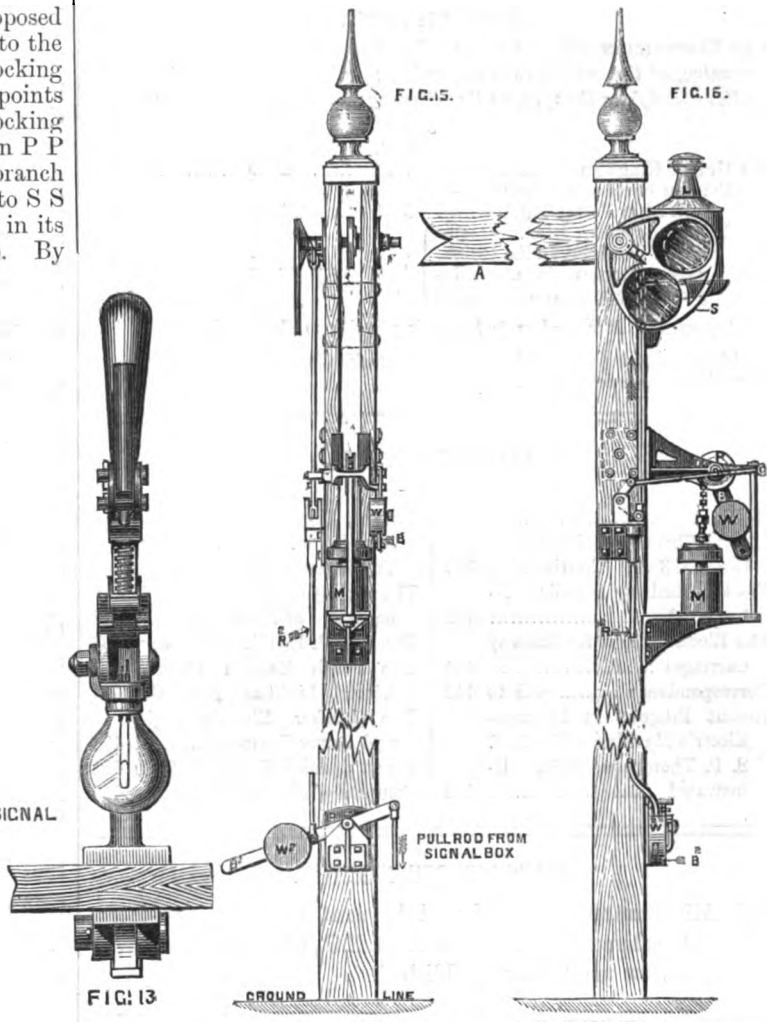
Digitized by Google

semaphore. The small resistance wire which takes up the return current, instead of allowing it to go directly through the rail, reduces the amount of current passing through the magnet from 5 amperes to ·125 ampere, and thus economises the electric current. A reference to Fig. 7 shows that ·125 ampere is more than sufficient under all possibilities to keep the signal arm down—*i.e.*, "line clear." Where only one signal is worked a single switch is used; where two or more signals are worked from the same box, multiple or commutator switches are used, making it impossible to "free" more than the right.

We may now refer to Fig. 14, and it will be seen from this that all the signals and points which are not actually required to be in operation are locked, and cannot be worked at the same time as those just described.

As an example of the method of working, let it be supposed that an up main line train is required to be sent on to the branch. It will be necessary to work the points 7, the locking bar 6, the signals 1, 3, and 5. The normal position of points being as shown on drawing, it is necessary to pull the locking bar and point lever forward, making connection between P P (6) and P P (7). The points are then set right for the branch line. Then tracing the connection onward we come to S S (8), down branch point lever, which must be back or in its normal position. Then from S (8) we come to E (3). By





putting switch (3) forward the connection is made between E H L (3). On the switch touching L (3), current runs through B B (2) to signal 3, which is lowered. Also the current runs from H (3) to E (1), and on the switch (1) being put forward, E H L (1) are connected, and signal 1 lowered. Similarly the current runs through P P (6), P P (7), S S (8), E H L (5), B B (4), B B (10), to signal 5. For instance, in the example of working just given we send an up main line train on to the branch. Therefore the down home main signal 10 should not be lowered. By reference to the diagram it will be seen that if the signal 10 were lowered, *i.e.*, the switch (10) put forward to make connection E H L (10), then B B (10) would not be connected, and therefore signal 5, up branch departure, could not be lowered. Similarly, the other signals are all interlocked, so as to secure absolute safety. It may be here mentioned that the points and locking bar 6, 7, 8, may be worked either by electrical power, or by the ordinary levers in the usual manner, the levers in the latter case being furnished with the contact pieces similar to the electrical switch levers.

The cost of the current employed is of course a matter of some importance. It is, however, small, and at Gloucester is furnished by secondary batteries, which for several reasons the Messrs. Currie and Timmis consider better than primary batteries. There is, as already explained, a continuous current of electricity running while the signal arms are down "line clear," so that the normal condition of every signal is at "danger." Every signal arm is pulled down "line clear" by its magnet; and, though at the moment of maximum pull five amperes is sufficient, a maximum current is provided of 10 amperes. When the armature of the magnet is home—*i.e.*, the signal arm is down "line clear," and the resistance is switched in automatically, the current is reduced to the "retaining" pull, which is taken at ·2 ampere. The time that each signal arm may be down "line clear" is calculated at twelve hours out of each twenty-four. The times that each signal arm may be lowered in each twenty-four hours is calculated at 150. On these data we have the following as estimated cost of current:—

150 lowerings of 2 seconds each = 300 seconds × 10 amperes = 50 ampere min.... = ·8 amp. hour.
Retaining pull, 12 hours × ·2 ampere ..... = 2·4 „ „

Amp. hour, per signal, per 24 hours = 3·2 „ „

C as above = 3·2.

R resistance = 5 ohms.

E = CR = 10 (max. current) × 5 = 50.

$$\text{H.P.} = \frac{CE}{746} \text{ watts} = \frac{3{\cdot}2 \times 50}{746} = {\cdot}2$$

Thus electrical expenditure per signal arm per 24 hours = ·2 H.P. = 1·2d. This cost is based on the assumption that E = 50, whereas the current used is only one-third of the maximum provided, which is double the maximum used, and the inventors thus estimate that the real cost of signal arm per twenty-four hours is not much more than ½d.

## THE ELECTRIC LIGHT FOR RAILWAY CARRIAGES.

Mr. Massey's brief account of his experimental lighting of a Metropolitan District Railway train by electricity attracted a larger audience at the Society of Telegraph Engineers, and provoked a livelier discussion than the character of the paper seemed to warrant. Probably its chief attractions were the prospect of an honest statement of facts from which some useful deductions could be made, and the opportunity it afforded of airing several rival schemes concerning which any facts whatever have hitherto been remarkably scarce. The discussion filled up the meeting, and had to be adjourned. We shall therefore refrain from anticipating any conclusions to be drawn from it as a whole; but on the discussion, so far as it has gone, we venture to make some general observations in the hope of helping the adjourned meeting to grapple with the actual problem before it.

That problem is in reality complicated by many considerations, which neither Mr. Massey nor the advocates of any other electric lighting system appear to have realised. First and foremost the success of an experiment on a short local railroad goes for nothing in relation to the question of lighting the rolling stock on the main lines. Then it should be borne in mind that this latter problem is the only one demanding solution, not the lighting of trains which are already very well lighted. As a rule the local lines in and about the metropolis using gaslights are fairly served in this respect. It is true that the reasons which make the lighting of these trains by gas cheap enough to induce the railway companies to adopt it tell also in favour of the electric light. The trains are made up in block, the same engine runs the through journey, no portions of the train are broken off, and no foreign carriages get mixed with it. For a new line of this kind the experiment on the Kensington and Putney branch will probably prove that the electric light could be installed and worked as cheaply as gas. But as to any existing line abandoning its present plant of gas lighting appliances in favour of electricity, the experiment proves nothing at all. Where perhaps there is competition, and the question of superseding oil lamps by a superior kind of light has arisen, there may be a chance for the electric light if Mr. Massey's figures can be taken as a basis for experiments with more permanent appliances and of longer duration. When we have said this much we have pretty well exhausted the comparatively simple but not very important problem of lighting metropolitan railway carriages.

But, turning to the more serious question of lighting for long journeys, where imperfect lighting, or positive gloom, is the rule—and a grievous one for the travelling community—the difficulties are very serious, and certainly did not receive the attention they deserve at the hands of those who took part in the discussion last week. If we may trust the report of some of the speeches delivered on that occasion the prevailing notion seemed to be that either the public or the railway companies, or both, are eager to adopt the electric light, and are only waiting for somebody to submit a practicable scheme. The sooner this notion is exploded the better. The oil lamps, which of necessity the railway companies are compelled to employ, are confessedly inadequate; but there is no particular anxiety to improve them. And as to the travelling public, what they want is a more cheerful light—one that they can read by, and that will help to pass the tedious hours away; but they do not care a button whether it is electricity or gas or oil or other illuminant so long as it gives a better light; and to suppose that they would willingly submit to being in darkness at certain intervals if only they might have the electric light during the remainder of the time is simple infatuation. The attitude of the railway companies is, we apprehend, pretty much what it was when the firm of Siemens years ago offered to supply them with that kind of lighting. They had no funds. That will be their answer now, unless some method either of generating the power required for maintaining the light, or some process of charging the lights from self-acting sources is submitted to them at a reasonable cost. The superiority of one line over another in respect to lighting may have some effect in forcing improvements all round, and probably the use of accumulators on the London, Brighton, and South Coast Railway has done something in this direction. But in the main the great railways will reply "No funds" to every suggestion involving a great outlay, unless they can be sure of two things—first that the electric light will cost no more—at all events, not much more—than the existing light; and secondly, that it will not go out when lighted.

Fortunately the meeting had the advantage of hearing two thoroughly practical men on this subject—men who, besides being electricians, were able to speak the minds of the railway

Digitized by Google

companies. The long array of difficulties to which Mr. Spagnoletti invited attention ought to be of the greatest service to persons interested in promoting electric lighting for railways on a large scale. To all appearance hardly any of these difficulties had ever been thought of by the theoretical part of the audience. Mr. Langdon also, while lending his voice to the condemnation of primary batteries, pronounced very emphatically on the point we have referred to above. The extinction of the light would be fatal to its chances of adoption. There must be two lights wherever a long journey has to be taken; this at all events until an indestructible lamp has been invented. A good deal has been said about employing a lower power to prolong the life of the lamps, but only by way of saving the cost of renewals. But would it not be wiser to face the real question, which, in this relation, is not expense but darkness? It would be better to destroy every lamp after a certain time, and take the cost of their deliberate destruction into account, than to risk their extinction on a long journey. Mr. Langdon's additional item to the cost of an installation has therefore to be considered, and a practical assembly like the Society of Telegraph Engineers cannot lightly set it aside.

We have abstained from offering any opinion on the relative merits of the several schemes mentioned at the meeting, because so very much depends on what they will cost, and nobody was at all candid on this point except Mr. Massey, who, however, is not the interested advocate of a particular system, but only the exponent of one that he has tried. What does a primary battery or a secondary battery cost to buy and maintain? Will the gentlemen who so fluently dilate on the merits of these appliances kindly favour the adjourned meeting with that much needed and long looked for information? If they respond to this invitation their eloquence will not have been thrown away; if, on the other hand, they decline the invitation, this discussion, so far as they are concerned, might just as well have never taken place.

## CORRESPONDENCE.

### THE AMPERIAN CURRENT HYPOTHESIS.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: The direction of the induced currents in the armatures of dynamo electric machines seems to be a stumbling-block to many of your correspondents.

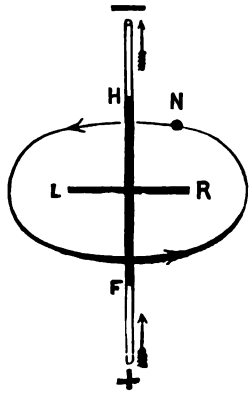

FIG. 1.

The solution of these problems is comparatively easy if we bring to bear upon them the well-known rule deduced from the laws of Lenz and Ampère.

The positive direction of the lines of force in a magnetic field is that along which a free north pole would itself be urged, viz., from the N pole to the S.

The lines of force round a wire conveying a current are circles, and their direction is thus determined by Ampère. Let the observer place himself in the wire, so that the current enters at his feet and leaves by his head (so that he may swim with the current); then a free N pole will be urged round him

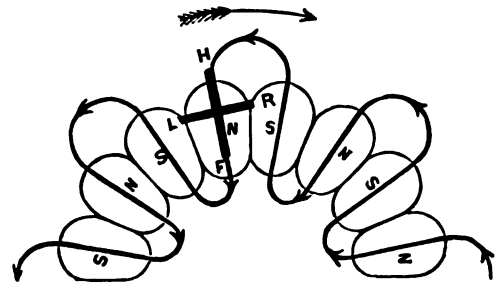

FIG. 2.—Ferranti Alternate Machine.

in circle which passes him in front from his right to his left (*see* Fig. 1). This is the old rule used for direction of swing of galvanometer needles.

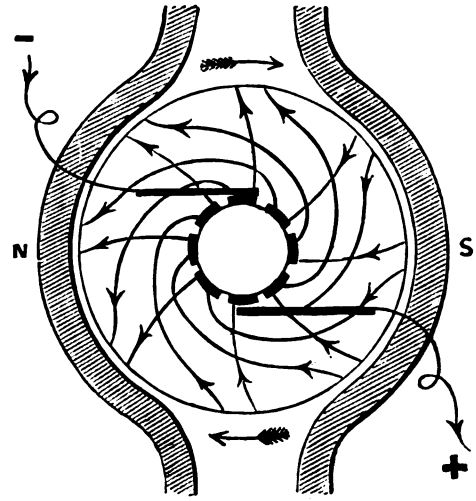

FIG. 3.—Siemens Machine.

Now, by the law of action and reaction, if the N pole in Fig. 1 be fixed, the wire itself will tend to move to the observer's right.

Generally, if an observer (theoretically, of course) place

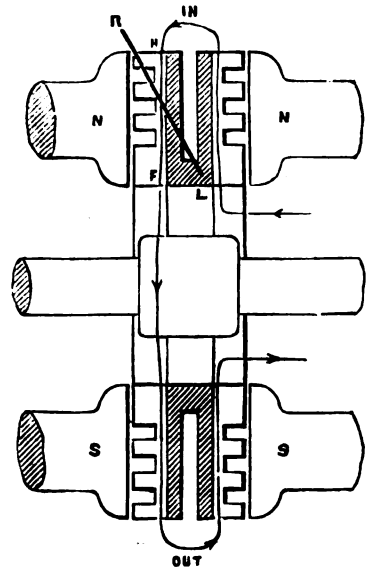

FIG. 4.—Brush Machine.

himself in a conductor so that he looks to the N pole, the lines of force therefore enter at his chest; then, if the current flows from his feet to his head—he therefore swims with the current—the conductor will tend to move to his right.

If we alter the direction of the current or the pole of the magnet the direction of motion is reversed.

It is necessary, then, to place yourself—a feat extremely

Digitized by Google

easy in imagination—in a short length of wire on the armature looking towards the N pole, and while in that rather dangerous and unstable position, go through the above simple reasoning, remembering always the law of Lenz, that the currents set up in a wire moving in a magnetic field are in such a direction as to check the motion of that wire.

I enclose some sketches showing the application of the above rules in the case of several typical dynamos.

Fig. 2 represents the direction of currents in an alternating machine of the Ferranti type. Here, as in the other figures, the position of the observer is shown by the letters H.F.R.L.,

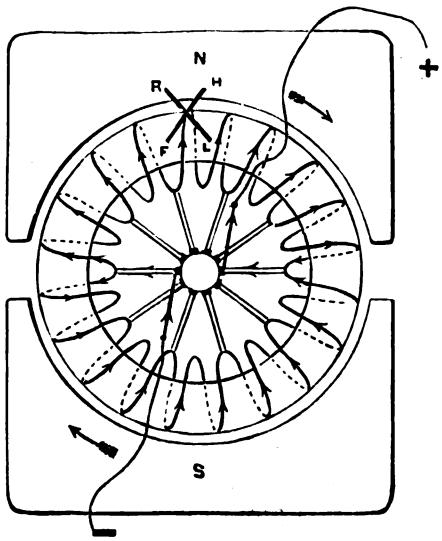

FIG. 5.—Gramme Machine.

representing his head, feet, right and left hands. In this case, by the rule, a current flowing from F to H will cause the wire to move to his R. But this will tend to help the motion of the machine, and not check it; therefore the current must flow from H to F, as marked.

Figs. 3, 4, and 5 show the Siemens, Brush, and Gramme machines respectively, and it is obvious that this method of reasoning is applicable to both dynamos and motors of every conceivable design, from the original simple copper disc of Faraday to the most complicated forms of the present day.—Yours, &c.,

C. M. DORMAN.

## PHYSICAL THEORY OF DYNAMO MACHINES.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: I quite agree with "E" that the lines of force theory applies to every dynamo machine. But why not use Faraday's simple and beautiful theory of cutting lines of force, instead of complicating it by talking of adding and subtracting lines of force to or from a coil or a "piece?"

"E" has, I confess, succeeded beyond my expectations in applying his theory to the Ferranti machine, at the expense, however, of fresh complications.

May I ask him if he can explain Siemens' so-called unipolar dynamo by the addition or subtraction of lines of force?

Mr. FitzGerald has not seen fit to notice my query, obviously because the amperian hypothesis does not readily lend itself to the explanation of dynamos of the Elphinstone-Vincent type.—Yours, &c.,

ONE OF THE CROWD.

P.S.—A description of Siemens' unipolar dynamo may be found on p. 275 of Vol. X.

## ON THE EFFICIENCY OF DYNAMOS.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: This subject having now undergone a considerable amount of able investigation, resulting in steady improvement of machines, it would be well for the sake of the profession at large that there should be standard forms in which to express the various efficiencies of dynamos. Much that was ambiguous has been cleared away, but there still remains an element of vagueness that should go also. Referring to *The Electrician* of September 23rd, 1882, we find record of exhaustive trials of certain Bürgin machines made (the trials) by Messrs. Crompton and Co. (The figures here given would of course give place to other of greater efficiency were Messrs. Crompton to publish their more recent trials.) My present object is to inquire how these figures were arrived at. Take, for example, Type $C_3$ shunt wound. Trial No. 1 of the first experiment. The total resistance of circuit does not appear to agree with the parts thereof, as given. Current in field magnets does not check with volts at brushes. The percentage of E. horse-power in various parts of circuit cannot be reproduced from the data; in fact, their true total would appear to exceed the total horse-power as transmitted to the dynamo. These points will probably become clear when we learn how the figures were arrived at. The useful work appears to check within a decimal, and the ratio to this to transmitted horse-power is clear enough. But how are we to understand "*transmitted horse-power?*" To take a more modern example from your columns of Feb. 16, 1884, wherein the various efficiencies of the Victoria dynamo are set forth with unusual clearness, we read "Actual horse-power absorbed 11·26." Absorbed by what? By the total electrical energy of 10·826 horse-power generated in the armature, plus Foucault currents, if any (pardon the suggestion), set up in the ring? Or does 11·26 horse-power include also windage of armature, friction of journals due to running at given (or, rather, not given) speed with load on? It is obvious that, whether these last-mentioned unpleasant sundries are, or are not, included under the 11·26 horse-power, it would be interesting to know by how much the "efficiency of conversion" 96·15 per cent. should be increased or decreased by their subtraction or addition to the 11·26 horse-power.

We require to separate the electrical from mechanical data, in order to truly compare one machine with another. And this is the more urgently required when it is attempted to gauge the performance of a machine in terms of lbs. of copper per watt, as is now sometimes done. We require, then, two more efficiencies, viz., total electrical efficiency = total electrical horse-power developed in armature coils, divided by (horse-power delivered to pulley with load on – horse-power delivered to pulley at same speed with circuits open) also total mechanical efficiency = total E. horse-power developed in armature, divided by horse-power delivered to pulley whilst generating. We should then get double answers to "efficiency of conversion," and to "commercial efficiency." "Increased friction due to load" has been purposely omitted, as it would introduce an element of uncertainty, not at present fully understood, and affording cover to the machines which require "lots of driving."—Yours, &c.,

March 1, 1884. R. E. DUNSTON.

## THE RECENT SUNRISES AND SUNSETS.

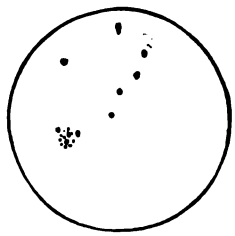
TO THE EDITOR OF THE ELECTRICIAN.

SIR: On the 12th September last, at Zanzibar, in lat. 6° 9′ 43″ S, long. 39° 11′ 15″ E, I noticed the sun had a very strange appearance all day long, and towards sunset it seemed to be enveloped in a transparent cloud, so much that any person could look directly at it with perfect ease, which on ordinary occasions would blind you for some time afterwards. Its outline was very clear and distinct, but its power appeared to have lost its effect. For nearly one hour after sunset the sky in the west was of a very deep red colour, and we thought at the time that an immense fire was raging on the mainland about thirty miles distant. The temperature that day was the same as usual. I did not take much notice of it the first day, but the succeeding one again bringing this strange appearance of the sun I took more careful observations. The sunrise was most picturesque, the sun's appearance being of a delicate *blue*, more like a full moon on a clear night than anything I can describe, and could be observed without the slightest difficulty. As on the previous day, its power seemed to be lost owing to a transparent cloud intervening. At noon it was a little more powerful, and the colour less blue, gradually changing to *green* in its decline. The tempera-

Digitized by Google

ture at sunrise, noon, and sunset was two degrees higher than the previous day.

At 5:45 p.m., a quarter of an hour past sunset, the appearance of the sun was a beautiful *silvery green*—such colouring I have never witnessed before; but something marred its effect to-day, which was not noticed the preceding sunset, and that was large clearly-defined spots on the sun, to be seen with the naked eye, and several smaller through an ordinary telescope. What seemed strange to me at the time was that they looked to be detached, *c'est-à-dire*, a long way from the sun, and as if floating in the atmosphere. The following is a fac-simile of a sketch I took from the ship's deck at the time mentioned:—Being an electrician my first thought on observing these spots was to ascertain if the submarine cables were in any manner interrupted by earth currents. Sun-spots proper always have had considerable effect on cables, at times so much as to stop the working; but on this occasion I found the cables were working as usual, and the earth currents very slight, with no particular change noticed. Of course on the following day I was anxious to see whether these spots remained, and to my surprise they had disappeared altogether. All this was a perfect enigma to me then, not having heard of the terrible



and wonderful eruption in the Straits of Sunda. The sun appeared for four days as above stated; the spots were not seen by me *only* on the 13th September. On each day after sunset the sky was of that deep red colour.—Yours, &c.,

WILLIAM H. COTTRELL,
Electrician, SS. "Great Northern," Eastern and South African Tel. Co.

## SPIRAL TELEPHONE WIRE.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: In Mr. Lumley's certificate, under date 25th ult. (which, so far as known to any person connected with this syndicate, was never intended to be used "privately"), it will be observed that he distinctly states that the tests when made by him were made and compared with the *wires*, not "one wire," as stated by Mr. Bennett. Then Mr. Bennett in his letter admits that the speaking on all the wires was good, *i.e.*, *including the spiral wire*. He, however, forgets to touch upon that part of Mr. Lumley's certificate which reads as follows:—

"The wire is No. 13 gauge, and weighs 110lbs. to the mile, against 220lbs. of the ordinary No. 11 iron wire, generally in use for telegraphic and telephonic purposes. Its lightness makes it much easier to manipulate; the cost of erection will thus be reduced as against the No. 11, and the public safety much increased. At one time the tests were made under specially disadvantageous circumstances for the spiral wire, it being in contact with another wire, but this seemed in no way to affect the speaking."

This, and the fact that the spiral wire speaks well, as admitted both by Mr. Lumley and Mr. Bennett, is all that can possibly be expected from the spiral wire for short distances.

The inventor, however, asserts that with the spiral wire he has talked, and can talk *clearly* and *in whispers* in all kinds of weather, at a distance of nearly ninety miles. This fact has been fully proved in the United States, and a sufficient quantity of the wire is now on its way from that country, so that positive proof will also be afforded in England.

The following communications recently received from gentlemen of the highest standing, and who are all connected with telephone companies, fully corroborate the statements made by the inventor.

The vendor will not touch one penny of the money belonging to the syndicate until the long distance speaking has been fully verified to the satisfaction of the directors.—Yours, &c.,

W. H. SMITH and SON, Solicitors to the Company.

Gresham House, March 18, 1884.

(Copies.)

No. 48, Central-street, Lowell, Massachusetts.
February 19, 1884.

My Dear Sir: I hereby certify that I have had occasion to use the line of spiral wire strung from Boston to our city, a distance of thirty miles, and also the line strung from Boston to Concord, N.H., a distance of eighty miles. I have also from time to time had occasion to use the old lines of common wire over the same routes, and I have found the difference to be very marked. First, induction on the spiral wire in all instances was almost entirely obviated, articulation was very clear and distinct, and a whisper from Boston to Lowell could be distinctly heard. I have also had occasion to talk with business men in Boston and Lowell who had talked over the wire in question, and it was their unanimous opinion that it was a great improvement in telephone service. I talked with the Attorney-General for the State of Maine over the line, he being in Boston and I in Lowell, and his remark in reference to the spiral wire was, "Why, Mr. Harris, this is perfectly wonderful." I conversed over the line from Lowell to Boston, standing 20ft. distant from the transmitter and speaking in an ordinary tone. My conversation was repeated by the person whom I was talking to to a third person who stood with the handpiece at his ear at the transmitter.

With reference to the line which has been strung from Boston to Concord, a distance of 80 miles, I was informed by telephone managers that prior to the stringing of the new wire it was impracticable to converse over the old lines from the two points mentioned. On the opening of the new line I conversed over it with different persons, one of whom was ex-Governor Weston, of N. H. I said, "Well Mr. Weston, what do you think of the new line?" He replied, "This is just what we want; we never before have had telephone service from here to Boston that amounted to anything. This talks all right." On another occasion I talked with one of the operators at Concord. I asked, "How does the new line work?" He replied, "All right, we talk from Concord to Boston without any difficulty. It is certainly a great improvement over the old wires."—Respectfully yours,

(Signed) Simon B. Harris.

Office of Fish, Kimpley, and Plummer,
27, Central-street, Lowell, Mass., Feb. 20, 1884.

Sir: I congratulate you on the success of your invention of the spiral telephone wire. The line constructed between Boston, Mass., and Concord, N.H., 80 miles, works like a charm. A short time since I with others experimented in talking over the line from this city to Boston and Concord, and from Concord to Boston. The result was perfectly wonderful. Could talk with parties 80 miles away with perfect ease, in the lowest tone of voice, even in whispers. It was remarked by some present that the parties to whom we were talking did not seem to be more than a few feet apart. This wire seems to overcome the induction so troublesome in other wires. With proper management the spiral wire will take a high rank in the telephone business of this country.—Yours truly,

(Signed) Chas. Fish.

Boston, Feb. 20th, 1884.

Dear Sir: I have had several opportunities of testing the spiral wire stretching from the office of the company to Concord in New Hampshire—a distance of 75 miles in a direct line, but 84½ miles by the wire—and have been surprised at the results. Not only is the voice heard with clearness, but even a whisper was heard with distinctness from Concord. The message was also heard when the operator at the other end was at a distance of 18 feet from the transmitter. This he told me at the time. Whatever may be the theory that explains this extraordinary improvement, the fact must be

Digitized by Google

admitted that the improvement shown by the spiral wire over all others hitherto in use is clear and undoubted.

I am, very truly yours

(Signed), F. E. Oliver, M.D.

P.S.—I ought to add that on one of the days when I tried the wire the weather was damp and rainy, and while the ordinary wire was entirely useless, as was proved by our vain attempts to use it, the spiral wire showed no diminution of power. F. E. O.

Lowell, February 21st, 1884.

Dear Sir: Having talked over your Concord wire, I am satisfied that it is the best wire I have ever used. The sounds came to the ear clear and distinct, and owing to your wire having less induction and leakage than other wires, conversation can be carried on in whispers.

I consider your wire a decided improvement over all other telephone wires now in use.

Yours truly,

(Signed), Wm. E. Livingston.

## RESISTANCE EXPRESSED AS A VELOCITY.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: I thank you for your note on the above subject in last week's issue. I will endeavour shortly to formulate a table of results as suggested, and should be glad if any one would undertake a similar task for the sake of comparison.—Yours, &c., SYDNEY T. DOBSON.

Ealing, March 19th.

## A BATTERY FOR ELECTRIC LIGHTING.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: I should be extremely obliged if any of your readers could tell me how to make a battery, either primary or secondary, small enough to carry about to light a half candle-power incandescent lamp?—Yours, &c., CONSTANT READER.

ERRATUM.—THE PHYSICAL THEORY OF THE GRAMME MACHINE.—Mr. FitzGerald writes to point out that in the diagram accompanying his letter (p. 422), the reverse direction to that shown by the arrow heads upon the line should be indicated at C.

## RECENT PROGRESS IN DYNAMO-ELECTRIC MACHINES.*

By Professor SILVANUS P. THOMPSON, B.A., D.Sc., M.S.T.E.
University College, Bristol.

(CONTINUED FROM PAGE 419.)

The height of the ordinate of this second curve at any point is proportional to the total area enclosed under the first curve up to the corresponding point. Thus the height at 90° in the second curve, is proportional to the total area up to 90° below the first curve. And it will be noticed that though the induction (first curve, Fig. 5) decreases after 90°, and falls to zero at about 102°, the sum of the potentials (second curve, Fig. 6) goes on increasing up to 102°, where it is a maximum, and after that falls off, because, as the first curve shows, there is from that point onwards till 180° an opposing false induction. If this potential curve were actually observed on any dynamo, we might be sure that we could get a higher electromotive force by moving the brush from 108° to 102°, or to 258°, where the potential is higher. Any dynamo in which the curve of potentials at the commutator presented such irregularities as Fig. 6, would be a very inefficient machine, and would probably spark terribly at the collector. It is evident that the induction in some of the coils is opposing that in some of the adjacent coils.

Two questions naturally arise—Why should such detrimental inductions arise in the ring; and how can they be obviated? The researches of Dr. Isenbeck supply the answer to both points. Dr. Isenbeck has calculated from the laws of magnetic potential the number of lines of force that will be cut at the various points of the path of the ring. He finds that the complicated mathematical expression for this case, when examined, shows negative values for angles between 12° and 90°. The curves of values that satisfy his equations have minima exactly in those regions where his experiments revealed them. This is very satisfactory as far as it goes. But we may deduce a precisely similar conclusion in a much simpler manner, from considering the form and distribution of the lines of magnetic force in the field. These are shown in Fig. 7, together with the exploring coil situated as in Fig. 4. A simple inspection of the figure will show that at 0° a certain number of lines of force would thread themselves through the exploring coil. As the coil moved round toward the S pole, the number would increase at first, then become for an instant stationary, with neither increase or decrease; after that a very rapid decrease would set in, which, as the coil passed the 90° point, would result in there being no lines of force through the coil. But at the very same instant the lines of force would begin to crowd in on the other side of the coil, and the number so threaded through negatively would increase until the coil turned round to about the position marked T, where the lines of force are nearly tangential to its path, and here the inversion would occur, because, from that point onwards to 180°, the number of lines of force threaded through the coil would decrease. We see then that such inversions in the induction must occur of necessity to a small coil rotating in a magnetic field in which the lines of force are distributed in the curved directions, and with the unequal density which this disposition of the field-magnets presents. The remedy is obvious; arrange a more uniform field, in which the lines of force are more equally distributed, and are straighter.

If an iron core be substituted for the wooden core, the useful induction is greater, and the false induction less; there is still an inversion, but it takes place at about 25° from the pole, and is quite trifling in amount. The introduction of iron pole-pieces extending in two nearly semi-circular arcs from the magnets on either side has, if the wooden ring be still kept as a core, the effect of completely changing the induction, so that the curve, instead of showing a maximum at 90° from starting, shows one at about 10°, and another at 170°! If, however, we make the double improvement of using the iron pole-pieces and the iron core at the same time, the effect is at once changed. There are no longer any inversions, though the induction shows some peculiarity still. Fig. 8 shows the curve of induction adapted from Dr. Isenbeck's paper, and Fig. 9 the curve of potential, which I have had integrated from it. Looking at Fig. 8, we see that on starting from 0° induction soon mounts up, and becomes a maximum at about 20°, where the coil is getting well opposite the end of the encircling pole-piece. From this point on, though the induction is somewhat less, it still has a high value, showing a slight momentary increase as the coil passes the pole at 90°, and there is another maximum at about 160°, as the coil passes the other end of the pole-piece. My integrated curve (Fig. 9) tells us what would go on at the collector if this were the action in the connected set of coils of a Pacinotti or Gramme ring. The potential rises from 0° all the way to close upon 180°. Still this is not perfect. In the perfect case the potential-curve would rise in perfect harmonic wave form, like that shown in Fig. 2. Fig. 9 departs widely from this, for it is convex from 0° to 90°, and concave between 90° and 180°. But there are no inversions. The cause of the improvement is easily told: the field—such as there is between the pole-piece and the core—is "straighter," and the density of the lines of force in it more uniform. I proved this experimentally in 1878, by the simple process of examining the lines of force in such a field by means of iron filings; the actual filings, secured in their places upon a sheet of gummed glass, were sent to the late Mons. Alfred Niaudet, who had requested me to examine the matter for him. Fig. 10 shows the actual field between the encircling pole-pieces and the iron ring. It will be seen that, though nearly straight in the narrow intervening region, they are not equally distri-

* Paper read before the Society of Arts, Feb. 28, 1884.

Digitized by Google

buted, being slightly denser opposite the ends of the pole-pieces. One other case examined by Dr. Isenbeck we will glance at. The effect of introducing within the ring an interior magnet, having its S pole opposite the external S pole, and its N pole opposite the external N pole, was found to assist the action. The induction-curve is represented in Fig. 11. As will be seen, there are two maxima at points a little beyond the ends of the pole-pieces, as before; but in between them there is a still higher maximum, right between

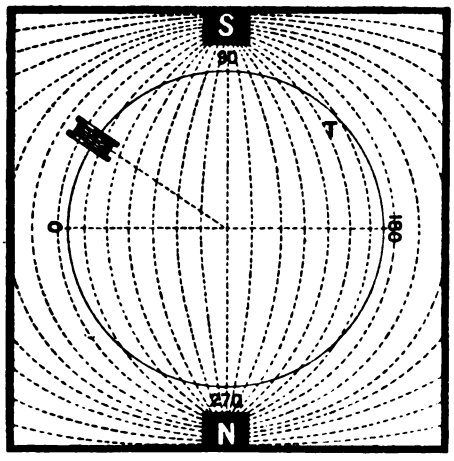


Fig. 7.

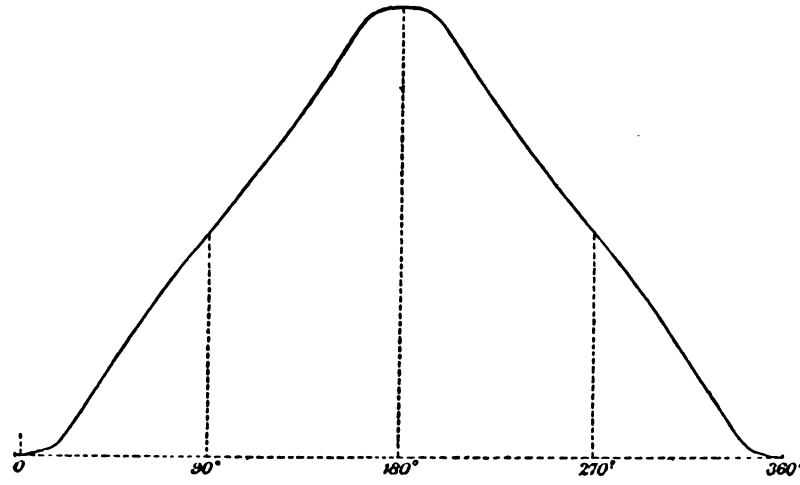

Fig. 9.

the poles. This case also has been integrated on Mr. Boys' machine, and shows the potential curve of Fig. 12. This curve is a still nearer approach to the harmonic wave-form, being concave form 0° to 90°, and convex from 90° to 180°.

I pass from Dr. Isenbeck's researches, and the integrated curves of potential which I have deduced from them, to some further researches of my own, which were undertaken with the view of throwing some light on the question whether the

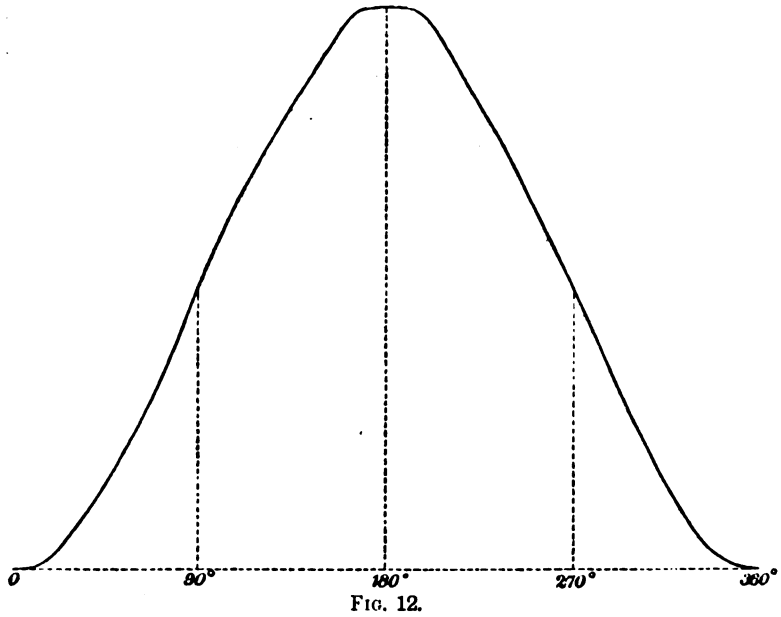

Fig. 12.

Pacinotti form of armature, with protruding iron teeth, or the Gramme form, in which the iron core is entirely overwound with wire, is the better. It has been assumed without, so far as I am aware, any reason assigned, that the Gramme ring was an improvement on that of Pacinotti. Pacinotti's was of solid iron, with teeth which projected both outwards and inwards, having the coils wound between. Gramme's was made "either out of one piece of iron, or of a bundle of iron wires," and had the coils wound "round the entire surface." Now, the question whether the Gramme construction is better than the Pacinotti or not, can readily be tested by experiment. And experiment alone can determine whether it is better to keep a thickness of wire always between pole-pieces and the core, or to intensify the field by giving to the lines of force the powerful reinforcement of protruding teeth of iron. The apparatus I have constructed for determining this point is now before you. It is sketched in Fig. 13.

First, there are a couple of magnets set in a frame so as to give us a magnetic field, and there are pole-pieces that can be removed at will; in fact, there are three sets of pole-pieces for experimenting with different forms. Between the poles is set an axis of brass, upon which the armatures can be slid These armatures are three in number. One is shown in Figs. 14 and 15, and consists of two coils of fine wire wound upon a wooden ring; another armature is exactly like this, but is built up on a ring of iron wire; a third (shown in

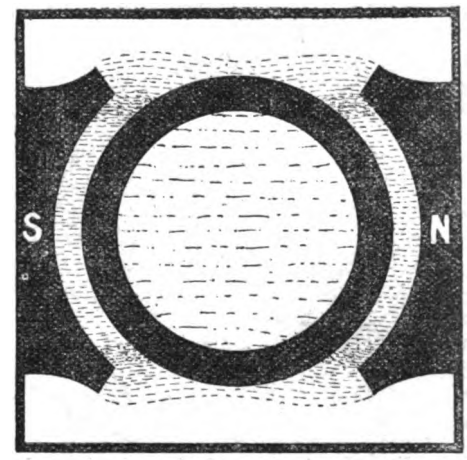

Fig. 10.--Iron Ring in the Magnetic Field.

its place in Fig. 13) is constructed upon a toothed ring made up of a number of plates of ferrotype iron cut out and placed flat upon one another. On each of the armatures are wound two coils at opposite ends of a diameter. The coils contain precisely equal lengths of silk-covered copper wire, cut from one piece. The cross section of the core within each of these coils is in each case a square, of one centimetre in the side, so that the number of turns in each coil is as nearly equal as

Digitized by Google

possible. I can slip any one of these armatures into the field, and connect it with a galvanometer. There is a lever handle screwed to the armature, by means of which it can be moved. I have used two methods of proceeding in order to compare the coils. One of these methods is to turn the armature suddenly through a quarter of a revolution, so that the coils advance from 0° to 90°, when the "throw" of the needle of the galvanometer—which is a slow-beat one—gives me a measure of the total amount of induction in the armature. The results are as follow :—

(TO BE CONTINUED.)

## AURORÆ, MAGNETIC STORMS, AND SUN SPOTS. By G. W. von Tunzelmann, B.Sc. *(Concluded from page 427.)*

We have already alluded to the earth currents which invariably accompany magnetic storms, and observations at magnetic observatories show that the magnetic disturbances vary according to the strength of these currents. This is what we should have expected, for we know that an electric current always produces magnetic effects in its neighbourhood, and indeed if we take a hoop of wire through which an electric current is passing, this hoop will simply be a magnet so long as the current continues. If it be freely suspended it will set itself, under the action of the earth's magnetism, in such a position that its plane is at right angles to the direction of a freely-suspended magnetised needle, and the direction of the current is the same as that of the hands of a watch placed within the hoop with its face southwards. The exact similarity

Digitized by Google

found to exist between the magnetic action of electric currents and that of ordinary magnets led Ampère to his explanation of magnetism as being due to the circulation of small electric currents round the molecules of a magnetic substance, and although the theory still presents some difficulties, these difficulties are probably due to the small extent of our knowledge about the nature of the molecules of which all kinds of matter are composed, together with our ignorance of what electricity really is. Ampère's theory completely explains all the known relations between the behaviour of magnets and that of electric currents, and is now the generally accepted explanation of magnetic action.

In the case of the earth it has been proved that all the phenomena of the earth's magnetism could be produced by electric currents in the earth, and if we suppose them to be confined to the surface, we can even determine the system of currents which would produce the observed magnetic effects. We may note also a series of observations made by M. Quetelet at Brussels, and extending over a period of about five years, which show that the atmospheric electrification is subject to a diurnal and an annual variation, both of which closely correspond to the similar variations in the magnetic declination. This identity of electrical and magnetic actions will naturally suggest the explanation of the observed connection between auroral displays and magnetic storms to be that the aurora is itself a phenomenon of electrical origin.

Humboldt, who observed a large number of auroræ in different parts of the world, gives an admirable description in his "Cosmos" of the commencement and successive phases of a complete display. He tells us that low down on the horizon, near where it intersects the magnetic meridian, the sky, which was previously clear, becomes darkened by an appearance resembling a dense mist, which gradually rises, and attains a height of about eight or ten degrees. The colour of the dark segment passes into brown or violet, and stars are visible through it, as in a part of the heavens obscured by thick smoke. Around the dark segment there soon arises a luminous arch, first white, but gradually turning yellow, and this arch undergoes frequent changes in its form, and sometimes remains for hours before rays and streamers are seen to shoot from it and rise to the zenith. The more intense the auroral discharges the more vivid is the play of colours, from violet and blueish-white through all gradations to green and crimson. At one moment the streamers rise singly, and are even interspersed with dark rays, resembling dense smoke; at another, they shoot upwards simultaneously from many and even opposite points of the horizon, and unite in a quivering sea of flame, whose splendour exceeds description, as its luminous waves continually assume new forms. The rays finally cluster round the point in the sky corresponding to the direction of the dipping needle, and these form what is called the corona—a canopy of light of milder radiance, streaming but no longer undulating. It is, however, only in rare cases that the phenomenon proceeds so far as the complete formation of the corona, and when this does take place the display is virtually over. The streamers now become fewer, shorter, and less intensely coloured, the corona and the luminous arches break up, and soon nothing is seen but irregularly scattered, broad pale shining patches of an ashen-grey colour; and even these vanish before the disappearance of the last trace of the dark segment, and the last that is seen of the display is often merely a delicate white cloud, feathered at the edges, or broken up into small, round masses, like cirro-cumuli.

The rays seen in the aurora are always parallel to the dipping needle, that is, they are in the same direction as the magnetic force, and the arches are portions of circles concentric with the magnetic pole.

The electrical origin of the aurora is very well illustrated by a common lecture experiment, bearing in mind that auroral displays always take place at considerable heights, and therefore in exceedingly rarefied air. We take a glass cylinder closed at the ends with brass caps, one of which is furnished with a stopcock communicating with an air-pump. To the brass caps are attached the terminal wires from a very powerful galvanic battery, or from a large induction coil, and we begin to work the pump. At first we perceive no result, but as the exhaustion proceeds, a soft tremulous light begins to play about the ends of the cylinder, and gradually extends right through it as the rarefaction of the air increases, but if the exhaustion be continued beyond a certain limit the light will gradually die away, showing that a certain amount of air is necessary for the discharge to take place.

If very powerful intermittent discharges of electricity are passed through tubes containing exceedingly rarefied air or other gases, striæ are formed, which look like a row of luminous discs at regular intervals along the tube, and these striæ are exactly analogous to the luminous arches of the aurora. Mr. Warren de la Rue, who has made these striæ the subject of elaborate investigation with his battery, which consists of over 16,000 cells, has also remarked how closely many of the colours seen in the aurora resemble those seen in the electric discharge as the rarefaction is varied. He finds that the colour of the discharge, which at a certain stage of the exhaustion is carmine, a tint so frequently seen in the aurora, changes as the exhaustion proceeds to a salmon colour, which gradually becomes paler, and ultimately when a still greater rarefaction is attained, becomes pale milky white.

Some experiments made by M. Planté with his powerful secondary battery, which has recently been improved upon by M. Faure and others, and has attracted so much attention in connection with the storage of electricity, show very clearly how the phenomena of the aurora may be reproduced on a small scale by means of the electric discharge. M. Planté immersed the negative terminal of his battery in a glass vessel containing salt water, and then placed the positive terminal in contact with the inside of the vessel which had been previously moistened with the liquid, and by varying the depth of immersion of one terminal, and the distance of the other from the surface of the liquid, he obtained a wreath of light surrounding the wire which was not immersed, or an arc bordered with a fringe of bright rays, or again, a sinuous line rapidly folding and refolding upon itself. Owing to the employment of salt water the light was chiefly of a yellow colour, but purple and violet tints similiar to those of the aurora were also observed at the parts where the water from the condensed vapour was less charged with salt. A dark segment surrounded the terminal, analogous to what Humbolt describes as seen in the aurora, and, as in the aurora, the fringe of light surrounded the segment. The liquid was violently agitated during the passage of the electric discharge, producing luminous vortices and rings, and when the experiments were made with only a small quantity of liquid, a luminous ebullition was produced, corresponding to the fluctuation of light so characteristic of the aurora. These experiments are of special value, because in them the discharge took place in the presence of aqueous vapour, which we know to be present in the atmosphere. M. Planté noticed that the greater the depth to which the negative terminal was immersed, the more abundantly and rapidly was aqueous vapour formed, and he suggests that this may explain the abundant falls of rain and snow which occur so frequently during the prevalence of polar auroras. When a magnetic needle was suspended near the wires leading from the battery, it was found that the deviation of the needle increased or diminished according as the luminous arc became more or less devoploped, showing a perfect analogy with the magnetic perturbations observed during an auroral display.

As the result of these investigations, we are warranted in concluding that the aurora is due to electrical action, and therefore the connection shown to exist between auroral displays and magnetic storms is satisfactorily accounted for; it remains for us to inquire into the relation between these magnetic disturbances and the spots on the sun's surface. It is now completely established that sun spots are really great cavities in the chromosphere or atmosphere of the sun, which is composed of exceedingly hot gases, including the vapours of a large number of metals. These cavities are due to tremendous cyclones or whirlwinds in the chromosphere, and the formation of such a cavity is frequently accompanied by an uprush of glowing hydrogen gas, and it is in this way that the protuberances so often seen during a total eclipse of the sun are produced. The darkness of the spot is considered

Digitized by Google

to be due to the cavity becoming filled with gas somewhat cooler than the surrounding portions, which therefore absorbs some of the light given off from the lower part of the cavity just as the flame of a candle will cast a shadow if it be placed in the path of the rays of the electric light.

We use the term cyclone to describe these terrific solar storms because the terrestrial cyclones present the only analogy within our experience, but we must bear in mind that our most terrible hurricanes only extend over an area of some few thousand square miles, and the greatest velocity attained even by the most violent gusts is not greater than from 120 to 150 miles an hour, and then the general velocity is certainly not much more than 100 miles an hour. In the great solar storms, on the other hand, masses of glowing gas are carried up to heights of many thousand miles with a velocity which often reaches 120 to 150 miles a second, and the area of disturbance represented by the spot is often so great that our whole earth might be engulphed in it; for example, in the case of the great sun-spot which was seen during the prevalence of the auroræ of November, 1882, our earth might have passed through the mouth of the cavity at its broadest part, and yet not have come within some two thousand miles of the edge upon any side. On the 7th September, 1870, Professor Young, an eminent American student of the sun, was observing through a spectroscope attached to his teleseope an enormous protuberance, or hydrogen cloud, upon the edge of the sun. Professor Young tells us that observing it on that morning he found that it had undergone very little change since the preceding noon. It consisted of a long, low, quiet-looking cloud, neither very dense nor very brilliant, and indeed in no way remarkable except for its size. It was made up of nearly horizontal filaments, and floated over the chromosphere at an elevation of some 15,000 miles, but was connected with it, as is usually the case, by three or four vertical columns brighter and more active than the rest. It was about 100,000 miles long by 54,000 miles high. At half-past twelve Professor Young was called away, and there was no indication of anything unusual being about to happen, excepting that one of the connecting stems had grown considerably brighter, and was curiously bent to one side, and near the base of another a little brilliant lump had developed itself. On returning at five minutes to one Professor Young was astonished to find that the whole thing had been literally blown to shreds by some inconceivable uprush from beneath. In the place of the quiet cloud which he had left there was nothing but *débris;* a mass of detached filaments had replaced the pillars and these filaments were much brighter and closer together than the pillars, and were rapidly ascending. At the time of his return some of them had already reached a height of about 100,000 miles, and as he watched them they rose with a motion almost perceptible to the eye, until in 10 minutes the uppermost were more than 200,000 miles above the solar surface, the velocity of ascent being about 166 miles a second. As the filaments rose they gradually faded away like a dissolving cloud, and at a quarter past one only a few filmy wisps, with some brighter streamers lower down near the chromosphere, remained in place. In the meantime the little brilliant mass before alluded to had grown and developed into a mass of rolling and ever-changing flame. At first it appeared low down upon the solar surface, afterwards it rose like a pyramid to a height of about 50,000 miles, then its summit was drawn out into long filaments, curiously rolled backwards and downwards, and finally it faded away, and by half-past two it had completely disappeared.

If we contrast these mighty cataclysms with our own puny hurricanes, and remember the, to our ideas, tremendons displays of thunder and lightning with which the hurricanes of the tropics are accompanied, we may be able to form some faint idea of the enormous development of electrical action which may be expected to take place in the sun. The question will here probably occur to some, how is it that this electrical action can be transmitted through the ninety-three million miles of space which separate us from our great luminary? But to this we have an answer, for we have learnt from the study of the phenomena of light and heat, that the whole of the known universe, the whole space included between our earth and the most distant stars revealed to us by the piercing eye of the telescope, is filled with an exceedingly elastic medium which has received the name of luminiferous ether, from its first discovered function of transmitting those vibrations which, when received upon the retina of the eye, produce the sensation which we call light. In the case of the sun, the vibrations of light and heat reach us in about eight minutes after starting on their journey, which they accomplish with the enormous velocity of about 186,000 miles a second, but in the case of the more distant stars, which are really distant suns, some smaller, some larger than our own, the rays of light which now enter our eyes have existed as vibrations in the luminiferous ether for many hundreds, probably in some cases for many thousands of years, as they sped on in their tremendous journey from distances utterly beyond the grasp of the human intellect. This medium gives us the solution of our difficulty, for the theoretical deduction from certain electrical measurements tells us that the velocity of transmission of an electrical disturbance is the same as the ascertained velocity of light within the limits of the errors incidental to both determinations. As yet the reason of the periodicity of sun-spots, and therefore of the corresponding terrestrial phenomena, is unknown to us, although some observations made by Messrs. Warren de la Rue, Balfour Stewart, and Benjamin Loewy, have led them to believe that this periodicity is connected with the relative positions of the sun and planets. If these results are confirmed by further investigations they may be expected to lead us on to fresh discoveries by a path of fascinating interest, but any attempt to follow such a path until this confirmation has been obtained would only result in leading us from the fertile fields of legitimate scientific inquiry into the arid deserts of futile speculation.

## THE SOCIETY OF TELEGRAPH ENGINEERS AND OF ELECTRICIANS.

At the meeting of this society, held on Thursday, 13th inst., Mr. W. H. Massey's paper, entitled "Notes on a Train Lighting Experiment," was read by the secretary, and was followed by a lively discussion. Mr. Massey's notes related to a recent experimental trial of electric lighting for train purposes conducted by him on the Metropolitan District Railway. Previous to this trial little had been known as to the cost of such lighting, but it was generally assumed that it would be higher than that of compressed gas or oil; but the result of his practical trial went to show that the original plant would not cost so much as had been expected, and that if the dynamos ran long enough at a time the system would be as cheap as compressed gas, which was considered the best and cheapest of existing lights. Gas was said to cost 12s. per 1,000 cubic feet; but the railways find that in making it for themselves it costs more. Taking this as the lowest price at which existing light was supplied he had compared with it that of the recent experiment with electric lighting, and he found that it worked out something less. The experiment itself was described in our issue of January 12th. The engine and dynamo were placed in a separate van attached to the train, the total weight including coal and water not exceeding three tons. As the trains on that line are permanently made up, the cable was simply run along the roofs of the carriages, suitable branches being inserted in the lamp-holes for connecting with the electric lamp. Fifty Swan lamps were used—thirty in the carriages and twenty more in the break, the idea being to ascertain the total expense of maintaining about fifty lights, which would usually be sufficient for a train of average length. The train on which the experiment was tried was one running between High-street, Kensington, and Putney. It worked well for 15 days without any hitch, and was resumed again with equal success subsequently. The light was excellent, and, if anything, rather too strong. One important point established was that with the conversion of 240lb. of water into steam 50 lamps could be maintained for one hour. Better results might be anticipated with specially-designed engine and dynamo, those employed on this occasion being simply the handiest available at the time. The consumption of coal was heavy, and he was himself in favour of using the steam from the locomotive. He estimated the cost of plant would be £170, the interest on which, added to the cost of coal, water, oil, and renewals of lamps, would bring the annual cost to £40, which was as 11s. compared with gas at 12s., and gave double the illuminating power. Mr. Massey thought, on the whole, that the system could be worked as cheap or cheaper than gas, and that the railway would be willing to incur the outlay on plant, as the damage done to their carriages by passengers' reading lamps was very serious. Mr. Massey then referred to the use of primary batteries, and to Mr. Preece's suggestion for employing air engines, but he thought that the direct method as tried on the District Railway was the best.

Professor Adams (president) spoke as to the life of the incandescent lamp. An 18-candle lamp worked at 10 candle-power would cost four-fifths of what it costs to work it at its full power, but its life would be much longer. It was therefore desirable to find out a medium of power

Digitized by Google

at which the cost of renewal and the cost of working would fairly counterbalance each other.

Mr. W. H. PREECE, after drawing attention to the general gloom in which passengers were compelled to travel, especially on the long journeys from London to the north, pointed out that these great main line trains were not made up in solid bodies, as on the local lines in and around the metropolis, but were in sections, which had to be separated at various junctions, each for their several destinations. The objection to employing steam from the engine was that the same engine did not go the whole journey ; and that in fact any system dependent on the continuous running of the train or engine would not answer, as the passengers would be frequently left in darkness. Secondary batteries had been used on the London, Brighton, and South Coast Railway with very satisfactory results no doubt to the railway company, but with probably very little satisfaction or profit to the company that supplied them. Their light, as a light, was a success, and perhaps the same could be said of the lighting by primary batteries, which had been recently tried on the Midland, the Great Northern, the South Eastern, and the South Western Railways ; but the cost of such lights was altogether unknown, the only certain thing about them being that they were very expensive. He himself was now engaged in experiments for the storing of compressed air pumped into reservoirs by the action of the wheel axles, and he was pretty confident that in this way he would get a cheap and efficient power with which a dynamo could be maintained at constant and uniform speed. The cost, considered in relation to the general working expenses of the great railway companies, was a mere fleabite.

After some eulogistic reference to the Holmes and Burke primary battery by a gentleman connected with one of the railway companies, but whose name did not transpire,

Mr. LANGDON gave his experience of this form of battery on the Midland Railway. He had found that 15 cells would maintain a lamp for ten hours, but that the liquid had to be replenished daily, and the plates twice a week. The battery gave off very offensive fumes, but no doubt the objection on that score could be obviated in practice by placing them in positions where they would not be a nuisance. The light produced was, however, insufficient, and the cost uncertain. He added the opinion that for all electric lighting of trains there should be not less than two lights, in case one of them should fail.

Mr. ALEXANDER SIEMENS stated that the firm he represented had on several occasions and many years ago offered to light trains by electricity, and had submitted estimates, but that the railway companies had invariably declined any proposals of a business-like character, pleading that they had no funds. As to employing primary batteries for this purpose, it was simply throwing money away. Over and over again inventors of primary batteries had been told by his firm that if they would leave the inventions in its hands for a week's test, and the result were satisfactory, the battery would certainly be taken up by the firm ; but up to this moment nobody had ventured to submit to such a test.

Mr. COLLETT warmly defended the employment of secondary batteries, stating that Mr. Knight, of the London, Brighton and South Coast Railway, had purchased the batteries used on that line outright, and the inference, therefore, was that he would not have done so if they had failed to give satisfaction. Seventy cells had been so purchased, and had been running well for 18 months, only one of them having had to be changed.

Mr. CROMPTON spoke in high terms of the Willans engine for electric lighting purposes employed by Mr. Massey in his experiment ; and expressed an opinion that, for the advantage of having the electric light in trains on long journeys, the public would not object to being deprived of it for a brief period at stopping or changing stations.

Mr. SPAGNOLETTI carefully reviewed the various schemes that had so far been tried or suggested for lighting trains by electricity, and pointed out many practical objections to any system that depended on the integrity of the make-up of the train. Neither the engines nor the carriages could be relied upon to complete the whole journey, and as different companies' carriages were mixed up on one and the same train, uniformity was out of the question. On the whole he thought that accumulators which could be stored at convenient stations, and placed in receptacles provided for them under or alongside the carriages would be the best method, involving the least outlay in converting the rolling stock, and the simplest as avoiding all mechanical difficulties.

The discussion showing no signs of flagging, the President suggested an adjournment, which was agreed to.

## THE BRITISH INSULITE COMPANY (LIMITED).

An extraordinary general meeting of the shareholders of this Company was held at the Cannon-street Hotel on the 18th inst., the Right Hon. E. P. Bouverie in the chair.

The SECRETARY (Mr. E. P. Greenhill) having read the notice convening the meeting,

The CHAIRMAN said : Gentlemen, when we met in this room about six weeks ago an examination of our accounts led to the impression, which seemed to be justified by the figures, that our business could in no circumstances be a profitable one. That, in a company whose object was profit, was a most material consideration, and the figures certainly rather startled ourselves as well as the meeting, as they seemed to indicate that. I promised that we would have a more thorough investigation of the accounts by our skilled auditors, Messrs. Price, Waterhouse, and Co., and that I would call you together on the part of the Board as soon as we could get the result of the investigation which they might make. The whole result of that inquiry is before you in the report we have had printed, and the simple explanation of the circumstances which startled us at the last meeting is this—that a very large addition had been made to the manufacturing charges, which was not due to them, but consisted of salaries to clerks and travellers, for goods, and also for a considerable amount of wages which had been spent in the early part of last year on experiments. These errors amounted altogether to £1,403, the mistake with respect to wages being £1,161. The total result was that we were £1,223 better with respect to manufacturing profit than we appeared to be by the accounts. The result was summed up in a paper I received from Messrs. Price, Waterhouse, and Co. After stating these facts, it showed a balance of gross profit for the year of £179. In the first five months of the year scarcely any sales were made, in fact none, and a considerable loss must have been made ; but the second half of the year recouped that loss, and left the nominal gross profit I have mentioned. Taking into consideration also the experiments referred to, a fair profit on the manufacture would have been shown on the half year. Messrs. Price, Waterhouse, and Co. recommended that we should have the stock taken for the two months' operations ending the 25th February. That was actually done, and an investigation made, and the outcome is laid before you in their report, from which it appears that a gross profit has been made on the two months' operations of between £700 and £800. Estimates are always unreliable, as there are variable elements, but it would appear from the investigation that, allowing for no increase of output for the year, and making a fair estimate of what the establishment expenses will be, at the present rate there will be a moderate net profit —something small, I will not say inappreciable, but not giving a large net profit. We, however, consider—and I think justly—that this business after all is in what we hope is only its infancy, and that it has in it the elements of successful boyhood and manhood. I do not wish to enter into the controversy raised on previous occasions, but I would say that we are quite as thoroughly satisfied as ever of the scientific value of the material with which we deal. We have every reason to suppose so, because the result of the trade we have had has been to induce people who have had our goods to come again. We have a large number of repeat orders from people of standing and position, and if the material were not what it professes to be, and if what we turned out were of no value people would not come again. The tendency of the position, therefore, is to induce us to believe that the business is capable of considerable expansion. Some of the most prosperous companies connected with the electrical trade have begun in great financial difficulties in the first few years of their existence, and have paid no dividends. I believe what is known as Silver's Company for a very long time yielded very little return, and there are one or two well-known companies in the City which have been in like plight before they paid dividends, and I do not think there is any ground for supposing that if we have the right stuff we shall be less successful than those companies have been. There is a firm who had some of our material in the shape of cells for a particular purpose for which the cells ordinarily used have proved an utter failure —Messrs. Lunds—and just after the meeting they wrote to say that they required more of our cells, and the letter expressed surprise that Dr. Fleming had not made more point of the successful test by the firm. I believe the result of that experiment, which was quite successful by these gentlemen, has proved thoroughly satisfactory since. I do not think there can be any well-founded doubt of the value of this material for any particular purpose. The result of Messrs. Price, Waterhouse, and Co.'s investigation brings us to this—that with a larger and increasing business (if we can succeed in making one) we ought to do very well. If our business does not increase we should live, but with an increase we should do very well, because we have turned the point where the gross profit of the manufacturing pays for the expense of the establishment. Our object (and we have been rather trying to effect this already) will be to reduce the cost of our establishment as low as possible. But that would be a comparatively trifling element if our business were relatively larger, and I think our efforts should be directed as much as possible to get as much business as we can. The charges will not at all increase in proportion to the extent of the business. If it had turned out on the investigation of Messrs. Price, Waterhouse, and Co. that our figures were what they appeared to be, and showed what they appeared to show, we should have had a very critical question to consider, because we should have had either to increase the price of the article we sold (always a delicate operation), or we should have had to consider the still graver question of closing the doors of the Company and bringing the whole affair to en end. But fortunately the result of the investigation has shown us that the elements of the calculation of the cost of what we produce were soundly based, and that it is possible—and probable, I would add—that the business may be made successful and profitable. I mentioned when here last that I was in communication with the parent company who sold us our patents. I was a shareholder in that company, as, I believe, most shareholders were and are. (No, no.) I was so confident of the material—as I am still—that I have put a great deal more into this Company than I got out of the old one ; and I should mention, when talking to you of the directors, that they hold a larger proportion of the shares themselves—very nearly one-fourth, I think, of the whole of the shares. That is by the way. I have been in communication with the chairman of the parent company, and I think we feel that the prosperity of both companies is largely mixed up together. If we prosper very much the shareholders of the original company will benefit by their "B" shares. They are entitled under these shares to half the profits after we pay 6 per cent., and I think this consideration was both a valid and sound one to induce the chairman of the parent company—as I hope it will induce the shareholders of the original company generally when the proposal is put before them—to consent to transfer their foreign patents to this Company on very moderate terms. The basis of those terms has been sketched out between the chairman of

Digitized by Google

the parent company and myself. I think they are highly satisfactory for the advantage of this Company, while they will not be injurious to the interests of the parent company. Practically it would amount to this—that those foreign patents would be transferred to us, which we hope in some cases would be of considerable value, and the main onerous condition would be that a moiety of any capital sum obtained for those patents on their sale should be for the benefit of the shareholders of the original company. So we should get the patents, the right of working them, the right of selling their produce for export, and we should also get a moiety—in case they were sold—of the capital amount which they would produce. This is substantially the basis of the terms provisionally agreed upon between the chairman of the parent company and myself. There is only one other point, which I have kept to the last, though not as a sort of *bonne bouche*. We have thought it necessary that we should make a call of £1 a share. We owe a considerable amount of money to our bankers. We think we see our way finally to carry on the affairs of the Company with this call. We are conscious that in the first place we had not enough floating capital to carry on the business in the way we have had to carry it on. We have had to erect some very costly machinery, which was at one time not contemplated. I ought to mention that what we sell is sold upon credit sometimes of two or three months, while we try to pay for most of our goods ready money. This keeps us out of our money for some time and necessitates the having an additional amount of floating capital. We have considered this very carefully at the Board. We believe that what we propose is sound and will ultimately conduce to the success and prosperity of the Company, and we trust that that call will be met readily, with a feeling of assurance on the part of the shareholders that the money will be carefully husbanded. We have agreed that the call shall be due at the end of next month—the 30th April. These are the principal points on which I wished to address a few observations to you. I ought to say that though the sales fluctuate, I notice a decided tendency upward in the amount of those sales, which I think is another demonstration of the public taking to what we can produce, and I feel perfectly sure myself that the merits of the manufacture are such that, when it becomes more generally known and the public are alive to its advantages, we are certain to reap the benefit of fair profits. I have never discoursed to you in an over sanguine spirit about these matters, but I entertain the same confidence I have ever felt in the merits of the invention from a scientific point of view. I believe the times we have fallen upon for our manufacture have been peculiarly unfortunate for us and all who are connected with the manufacture of electrical appliances. Every one knows that there was an extraordinary rush for electrical appliances two years ago, and every one knows that there has been an extraordinary relapse in the last twelve months in the demand. We shall give every attention to your business, and try and make it a successful one. More than that we cannot undertake to do. I think we have shown our interest in it—first by the large number of shares we have, and secondly by the fact that we have never drawn a penny of fees from the concern.

A SHAREHOLDER: They remain a debt, do they not?

The CHAIRMAN: Yes, but it is a matter which is in the womb of the future. I will now move that this meeting receive and approve the report of the auditors.

Sir GEORGE RICKARDS seconded the motion.

Mr. GEORGE FERGUSSON opposed the motion. As far as he could understand it, the Company was, he said, in a practically bankrupt condition, and he moved that it should be wound up.

The CHAIRMAN stated that no motion could be put that was not on the paper, and to submit such a motion an extraordinary general meeting must be called.

Mr. PRICE (of the firm of Messrs. Price, Waterhouse, and Co.) subsequently addressed the meeting, recapitulating the statements made by the chairman as to the recent investigation which had been made of the accounts of the past year and of the two months of the current year, and indicating how the mistake in the previous accounts had arisen. In the investigation which they had recently made he said each particular account had been analysed, and they had seen in what respect every liability had been incurred. Although the general result of the examination of the balance-sheet for the past year was precisely the same as that which appeared by the balance-sheet produced at the last meeting, yet when they came to apportion the items to various other entries the manufacturing account was seen to be relieved of some very large sums that should not have been debited to it. As to the examination which had been made of the working for the two months of the current year, the accounts showed that during that period there had been a manufacturing profit of about £750. That was at the rate of something even exceeding 50 per cent on the cost of the manufacture. He entertained no doubt as to the correctness of that account. If, therefore, they could make a profit, he would not say of 50 per cent., but of 40 per cent., or even less, upon the manufacturing account, and they could increase the sales, they would get a dividend, while if they reduced the expenses the concern would be so much the more benefited. He thought it was possible to reduce the expenses, and that the sales might be increased almost indefinitely; and as it appeared that the article itself bore a considerable profit, if it were true that the material itself was good in itself, and one likely to be in demand—and in increasing demand as its alleged merits were known—all he could say was that if they increased the sales by £2,000, £3,000, or £4,000 in the course of a year they would have to the good something like £3,000 or £4,000. They could make insulite if present prices were realised so as to give a satisfactory profit.

A SHAREHOLDER: What is a satisfactory profit?

Mr. PRICE said it depended on surrounding circumstances. He thought in a manufacturing company, if they could get anything between 5 and 8 or 9 per cent., it should be regarded as satisfactory. He was confident that with proper energetic management, assuming that there was a demand for the article, it could be produced at such a price that would yield a satisfactory dividend to the Company.

A SHAREHOLDER asked if there had been any net profit yet?

Mr. PRICE answered in the negative.

A further discussion ensued, and in reply,

The CHAIRMAN said that they had had to start a manufacturing establishment, and to get peculiar machinery to carry it on. They found that the article which they made in a particular stage, for which they thought there would be a considerable demand, did not meet with a ready sale, owing a great deal to the depression in the demand for electrical appliances generally. He thought, that being so, that they acted as sensible men in seeing whether they could not, by a modification of the material as previously made, get a sale for it, and the experiments which they had carried out were to find out in what way the article could be made to do so. If they could keep on their sales at the rate of those of January, February, and for the first two weeks of March they would get a fair profit. There seemed to be fair evidence to show that there was a demand for the article, and that there was an increasing demand for it. He was interested in other electrical companies, which had, he believed, the elements of success in them, but not for a time. The business to be a prosperous one must begin with a beginning, and until they had advanced it to a certain extent they could not expect it to be so prosperous as it would be after some experience, and after the public had been shown the advantages which the manufacture offered. It had been said that there had been mismanagement, but such a statement was easy to make. All that he could say was that they had done their best, and he thought that on the whole they had not been unsuccessful. He considered that their circumstances and the figures which had been mentioned to them had no discouragement about them. Dr. Fleming, a man of very great scientific experience, had been making experiments, and they derived immense advantage in having the voluntary assistance of such a gentleman. The material when they bought the patent was, as far as he knew, perfect, but the application of it was not fully developed. The process of making the material was perfect before they bought the patent, and the machinery was calculated to turn out a very large amount of what they wanted in a very short time. At first some of their critics told them that they could not make anything like the quantity that would be required, but with a little practice and skill their machinery turned out more than was required in a given time. They therefore shut off steam until they had used up the stock which had been made. If their business extended as they hoped, then it would be greatly to the advantage of the Company that the machinery was capable of turning out a great deal more than was wanted at the present time. He thought it was wise having the machinery devised and made on the assumption that there was to be a demand on a large scale, as up to a certain considerable point there would be no further expense for machinery. He hoped that the next call would be the final one. They did not contemplate calling up more than another £1. The directors had no disposition to call up any more money than was requisite for what they considered the fair development of the business. There was no profit in the raw shape of the material, but they did not sell the raw material. It was originally contemplated to manufacture the material in a very imperfect way, and the profit on the material in that condition would have been rather less than it was now when made up into a more complete article. There was nothing in the things which they turned out apart from the material.

Dr. FLEMING, in further reply to questions, stated that there was a profit on the material itself. It was perfectly absurd to say that a patent could not be held for a material, and there was a patent for this material. He was perfectly sure that there was a very large business indeed to be done not only in England but in the colonies, with all of which they could open business. They had executed some large orders for Egypt, and a large amount of goods had been sent out to the Cape of Good Hope, where there were no patents. They could transact business with all the other colonies. Not only had he not parted with a single share, but he had bought shares since the formation of the Company, and his holding in the Company was about one-eighth of the whole capital.

After some further discussion the motion was adopted by a majority of 18 to 9, and the proceedings terminated.

## THE SOUTH EASTERN (BRUSH) ELECTRIC LIGHT AND POWER COMPANY (LIMITED).

An extraordinary general meeting of this Company was held on Tuesday at the Cannon-street Hotel, Sir Michael Kennedy in the chair.

Mr. ALFRED JERMYN (the secretary) having read the notice convening the meeting,

The CHAIRMAN said that after the recent extraordinary general meeting, which passed off so pleasantly, the directors were rather surprised to be required to carry an arrangement under which the capital of the Company would be reduced to the amount already paid up. They thought that they had satisfied the great majority of the shareholders that they had inaugurated a hopeful business, and that they had their confidence in carrying out their programme to that effect. He took it, therefore, that the measure that had now been pressed upon them had been called for in consequence of something that had subsequently occurred and outside of this Company. He supposed that there was a sort of general feeling that the prospects of electric lighting were not at the present moment good, and there was a desire to wait and to restrict the outlay of capital as much as possible, waiting for better times. There might be, and perhaps there was, something in that, but he ventured to remark that this Company, at least in the opinion of the directors, was in a better position than that of most other companies which were started upon similar lines, and for

Digitized by Google

similar purposes, inasmuch as they had paid comparatively very little for their concessions. They were the first company that had started an installation upon a large scale to be worked from a central station, and under the provisions of the Electric Lighting Act; they had also large interests in a manufacturing company which they believed to have very good prospects of success. At the ordinary general meeting they explained as far as they were able to do so exactly what their position was, and at a conference that they had had quite recently with several of the principal shareholders of this Company, amongst others the gentlemen who had signed the requisition, they had done the same. The directors still thought that it would be better if no reduction were made in the capital, but that if any reduction were imperatively called for that it should not go beyond a reduction to £3 per share. As, however, they were unable to convert the gentlemen who met them to that view they consented to reduce the capital to £2 10s. per share. Beyond this they could not go, for the very good reason that their liabilities were in excess of any further reduction, and they could not, if they passed any resolution to that effect, obtain the consent of the Court to it, and therefore it would be futile and abortive. Even the reduction that they had now agreed upon would involve the loss of the provisional order, which had cost them not only a great deal of time and trouble and difficulty in obtaining, but also some £2,000, and if their prospects should turn out to be as good as they anticipated they would be, and if hereafter they should go in for extending their business, they would have to go through the whole of that trouble and expense again in order to get parliamentary powers to work their district. They told the gentlemen who conferred with them that if they would consent to reducing the capital to £3 per share they would agree not to call up more than £2 10s. per share, unless they had the consent of the consultative committee, before whom they would lay their reasons for the additional call, but they could not carry it to that extent. This proposal was not accepted, and therefore they were reduced to accept the utmost they could get, which was £2 10s. per share. At the same time they indicated to those gentlemen certain reductions in their usual charges which they were about to make, and in order to show that they had confidence in their judgment of the case, they also agreed that they would not receive any further remuneration as directors until they had been able to earn and declare a dividend. What they wanted to see was the success of this Company, and what their chief desire was was of course that the shareholders should not lose the money that they had already invested in the undertaking. They thought that this could be done in the way that they had indicated. They made this proposal as regarded foregoing their remuneration in connection with a proposal to reduce the capital to £3, but they were not going, of course, to retreat from that position because they had been compelled to accept a reduction to £2 10s. They would still carry out that arrangement in the future, and they trusted that they would be able to show a good result. He would now, as a matter of form, call upon some gentleman to propose the first resolution upon the paper. He had already said that he did not think that it would be any use if it were carried, because it must fall to the ground as abortive.

Mr. BLEWITT asked whether, if the resolution was negatived, it was the intention of the directors to support, by their own personal votes and proxies, the proposition to reduce the capital to £2 10s.?

The CHAIRMAN: Certainly.

Admiral INGLEFIELD asked what was the liability that had necessitated the call, and if that liability had taken place since the last general meeting?

The CHAIRMAN replied that the liability was borrowed money from the bank. They owed the Anglo-American £1,164, sundry creditors £115, the Consolidated Electric Company they owed money, and also the Provincial Brush.

Admiral INGLEFIELD asked if those debts had been incurred in reference to works now going forward.

The CHAIRMAN said that they were debts that had been incurred before the last general meeting.

Admiral INGLEFIELD continued to say that he was one of the members of the Metropolitan Brush Investigation Committee, and after sitting forty days, and carefully examining the affairs of that Company in reference to certain proceedings that were to take place afterwards, the result was that the shareholders were unanimously of opinion that the Company should be wound up. In the course of that investigation they had to go into very voluminous papers, and the result was that they were satisfied that, notwithstanding all the money that had been spent in the Metropolitan Brush, and notwithstanding all the good work that had been done, and all the good work that there was to be done, it was impossible to make the Holborn concession pay.

Mr. FRY rose to order, and said that this was not a meeting of the Metropolitan Brush Company.

The CHAIRMAN thought that they would be very glad to hear what Admiral Inglefield had to say.

Admiral INGLEFIELD said that what he wanted to say was this: They found there were enormous sums being spent annually on the staff, and next to no electric lighting going on. He and the other gentlemen on the Metropolitan Brush Committee had satisfied themselves that it was impossible in the present state of things, and in view of the enormous sums paid for concessions, to make electric lighting pay beyond a possible 2 per cent., and that, after all, would be a very small return on a very large capital. He was a large shareholder in the Metropolitan Brush. He was a shareholder in this Company and in the Provincial, and had been two years chairman of the Maxim-Weston, and therefore he had had some experience, and he did think that at the present moment there was no company which could make electric lighting pay. He believed they would do better if they had some inquiry on the subject, and see how far their money was going to be spent for their benefit.

A SHAREHOLDER asked for an explanation with regard to the £4,923 owing to the Consolidated Company. That appeared to be a large sum, and he should be glad to know if it was for the storage batteries, which had never been submitted to or tested by any competent electrical authority. He inquired whether any large portion was for the work done at Colchester? He also asked whether it was true that some £10,000 was likely to be spent at Colchester, and if so, on what they based their prospects of that installation paying?

Mr. BLEWITT said that he should have been very glad if they could have seen their way to reduce the capital £3, but if that could not be done it was far better in the interest of a large body of shareholders to have a certain reduction of £2 10s. He suggested that under the circumstances they should unanimously reject the resolution to reduce the capital £3, and vote for the one that it be reduced £2 10s.

It was then moved and seconded that the capital of the Company be reduced by £3 a share.

The CHAIRMAN in reply to questions said that the accounts before the ordinary general meeting were made up to the 30th of June, at which time certain liabilities had not arisen. As to the question with regard to the Consolidated Company, he might explain that, according to their arrangements with that Company, they were under a liability to them of £10,000 if required. Of that about half had been paid, and the balance remained. As regarded the Colchester installation, the shareholder was perfectly correct in supposing that the estimate amounted to about £10,000, and according to the estimates they had framed, and according to the rates they were already receiving at Colchester, when they attained to the estimated amount of lighting which they anticipated—that was about 2,200 lamps—they expected a return of about twelve and a half per cent. upon their outlay.

The motion was then put to the meeting and lost.

The CHAIRMAN said that he would now propose the second motion on the paper, and in doing so he only hoped that the expectations of the gentlemen who called this meeting would be realised, and that it would not hamper them should they be successful elsewhere in raising further capital, and that it would not in any way materially impede the progress of the Company's business. He moved that the capital of the Company be reduced from £100,000 divided into 20,000 shares of £5 each, to £51,000 divided into 400 fully paid up shares of £5, and 19,600 shares of £2 10s. each, and that such liability be effected by reducing the liability on each of the 19,600 shares to the extent of £2 10s.

Mr. FESSER seconded the motion.

A SHAREHOLDER asked when they anticipated making a further call of 10s., and if that would meet all the liabilities of the Company?

The CHAIRMAN replied that they would not make the call until they were absolutely compelled to do so, probably not for some months, and it would meet all the liabilities of the Company.

Mr. BLEWITT said that it frequently happened that, when application was made to register a resolution of this kind, from some informality the Court refused to register it, and he asked the directors to give the meeting a pledge that if it were refused the shareholders should be called together to give them an opportunity of expressing their views before carrying on the business.

The CHAIRMAN said that the directors' action in this matter must be perfectly well known to the gentlemen who had met them in conference, and that it was in good faith, and in good faith it would be carried out.

The motion was then put and carried unanimously.

The proceedings then terminated.

## THE GULCHER ELECTRIC LIGHT AND POWER COMPANY (LIMITED).

An extraordinary general meeting of the shareholders in this Company was held at the Cannon-street Hotel, on the 18th inst., under the presidency of Mr. Daniel de Castro.

The SECRETARY (Mr. Russell Day) having read the minutes of the meeting of the 27th ult., the notice convening the present meeting was taken as read.

The CHAIRMAN said that the object of the meeting was to confirm the special resolution which was passed at the last meeting, as follows:—

"That the regulations of the Company be altered by the addition of the following regulations:—(*a*) The directors may accept surrenders of shares on such terms as they think fit, provided that no part of the assets of the Company representing paid-up capital be employed in the purchase of the Company's own shares. (*b*) The directors may sell any surrendered shares, and register the purchaser as the holder thereof, and may cancel any share acquired by surrender, and may (unless the Company otherwise resolve) issue new shares in lieu thereof."

The CHAIRMAN formally moved the confirmation of this resolution.

Professor CROOKES seconded the motion.

The CHAIRMAN put it to the meeting, and declared it carried unanimously. Continuing he said: Gentlemen, now comes the real substantial business of the day, and it is really to give effect to the working of the past six months. I shall have to propose to you the following resolution: "That the conditions contained in the Memorandum of Association of the Company be modified by reducing the capital of the Company from £300,000 in 60,000 shares of £5 each, to £150,000 as in 30,000 shares of £5 each, and that such reduction be effected as follows:—1. By extinguishing 11,000 fully paid up shares of £5 each, and 12,000 shares of £5 each having £3 10s. called up, and £1 10s. per share paid up or credited thereon, agreed to be surrendered by Messrs. Charles James Fox, David Johnson, and Newson Dunnell Garrett. 2. By extinguishing 2,010 fully paid

Digitized by Google

up shares of £5, agreed to be surrendered by William Crookes, F.R.S., and 880 fully paid up shares of £5 each, agreed to be surrendered by Robert Jacob Gulcher, and 880 fully paid up shares £5 each agreed to be surrendered by Lorentz Albert Groth. 3. By cancelling 3,230 unissued shares of the Company which have not been agreed to be taken by any person." I feel it would be wasting your time to refer at any length to the meaning of these resolutions. They have been placed before you, first of all at your first meeting, and afterwards by a circular, which has been addressed to you, and which I have no doubt has been received by all of you. This is substantially the result of the negotiations with the promoters of the Company, by which they gave up the £70,000 mentioned in the circular which you have received. Over £20,000 has also been surrendered by Messrs. Crookes, Gulcher, and Groth, the vendors to the Company. The other money which we propose to reduce is the 3,250 unissued shares, which we propose to strike off in order to reduce our capital by one-half. I shall move now substantially that the resolution as read to you be passed at this meeting. It will have to be confirmed, if passed to-day, at a subsequent meeting in the same way as the first resolution, which you passed a little more than a fortnight ago, has been confirmed to-day.

Mr. KELLY seconded the motion.

The CHAIRMAN, having put it and declared it carried unanimously, said: A meeting will have to be held in not less than a fortnight to confirm the resolution. The real business of the meeting is now at an end, but if any shareholder has any suggestion or observation to make we shall be happy to hear him. At the last meeting I mentioned to the shareholders present that instead of making a further call on the shares we proposed to raise the money, which we really now urgently require for carrying on the business of the Company, by the issue of debentures. Your Board have agreed among themselves to subscribe £5,000 out of the £12,000 which we propose to issue. We hope you will supplement that subscription, and let us have the money to go on with. There is a very large amount of business being done and to be done. In the course of half an hour we are sending in a contract, which we have reasonable hope of getting accepted, involving an expenditure of £6,000. The Crystal Palace contract will involve, and is involving, a very considerable expenditure. This cannot be done without money. We have three or four other installations going on just now—one at Margate, which may lead to large results; one at Liverpool, which I mentioned before, only just completed; and we have another at Huddersfield, in Yorkshire, from which we expect very good things. All these are being carried on at the present moment, besides an installation we have the offer of, which the want of immediate funds alone prevents us from closing with at once. The last installation which I mentioned would bring into your Company at least £700 a year. The installation from the Crystal Palace brings another £700. Altogether we have now coming in in the way of income over £1,500 a year—and nearer £2,000; but this work cannot be done without money. We are very loth to call on the shareholders once more, because some of them were not prepared for the rapid calls which have been made on them. A large number of our shareholders are very wealthy men, and we look to them to ease those to whom these calls are more or less a burden by advancing money upon what we believe as a Board is ample security. We have given the best earnest of our belief by subscribing ourselves, and we shall be very glad of the assistance of the shareholders. The debentures will bear 6 per cent. interest, secured on the whole of the property of the Company. We have at present uncalled capital amounting to about £25,000—that is assuming the arrangements we have made to-day for reducing our capital to £150,000 are carried into effect. On this amount of uncalled capital these debentures will be a first charge. There are also the stock, plant, and material of the Company, which I think I am within the mark in saying are worth another £12,000, and there are with arrears of calls and with cash at least another £8,000 or £10,000, and then there will be the investment of this money itself. We should pay all our debts off, and I think, after we have received this £12,000 of debentures, we should have besides our stock, which I have put at £12,000, at least £8,000 to work with. That is really giving us £20,000, and with that we feel convinced that we shall not only declare a dividend, but make your shares, which are at present doubtful, of really marketable value.

In reply to questions, the CHAIRMAN added that the directors would be quite willing, instead of taking subscriptions from the shareholders in the form of debentures, to accept payment of the balance uncalled on the shares, giving 5 per cent. interest. They wanted at least for their work during the next two months to carry out their contracts £6,000. They would take payments on the debentures by instalments, and it was proposed to extend the debentures over three or five years. They were not at present ready to make an absolute proposal, but they would do so at the next meeting. It had been suggested that the debentures should be in sums of £50 or £100, and the directors would prefer that a large number of the shareholders should subscribe for small sums. The agreement as to Messrs. Fox, Johnson, and Garrett was not yet completed, and it would be idle to suppose that it would be until it had been confirmed by the shareholders.

On the motion of Mr. BLUNDELL a vote of thanks to the chairman and directors was passed.

The CHAIRMAN, in acknowledging the compliment, said that almost all they were doing was contingent on the agreement with the promoters being carried out. The agreement, however, was so eminently advantageous to both parties that he could not think there was the least doubt as to its being carried out. Before any debentures were issued, they were entitled to receive from any shareholder under the Articles of Association payment of his calls in advance. He had just heard of one matter which he thought it right to mention. One of the directors had withdrawn his subscription to the debentures as to £500, and proposed, instead of taking debentures, to pay up his shares in full. Therefore the subscription of the directors to the debentures would be £4,500, and not £5,000.

The proceedings then terminated.

## DIRECT SPANISH TELEGRAPH COMPANY (LIMITED).

Report of the directors for the half year ended 31st December, 1883, to be presented at the general meeting of shareholders, to be held on Thursday, March 27, 1884.

The annexed accounts for the half year ended 31st December, 1883, show a balance to the credit of profit and loss of £4,645 2s. 6d. The traffic receipts show a falling off of £870 17s. 7d. as compared with the corresponding half year of 1882, during which no interruption of the Bilbao cable occurred, whereas during the last half year this cable has been interrupted from the 6th to the 27th August, and from the 24th November to the end of the year. The Bilbao cable again broke down on the 10th February last, and steps have been taken for its restoration. The Marseilles-Barcelona cable has continued in excellent working order. The directors have concluded a contract with the Telegraph Construction and Maintenance Company for the construction and laying before the 15th June next of a duplicate cable between England and Bilbao, upon satisfactory terms. As will be seen by the accounts, the directors have paid for the repairs of the Bilbao cable in August last, amounting to £2,052 11s. 1d., out of revenue, but have deducted the cost of the repairs of the second interruption in November from the reserve fund, which is thereby reduced to £638 19s. 4d. The dividend on the preference shares for the half year will absorb £3,000, and after appropriating £200 to the reduction of preliminary expenses account, there will remain a balance of £1,445 2s. 6d., which it is proposed to carry to the reserve fund. The dividend warrants on the preference shares will be issued when the remittances from Spain for the balance of telegraph accounts to Dec. 31 last are received. With a view to more rapidly extinguish the preliminary expenses account, the directors propose to apply to the reduction of that account the £935 10s. 6d., amount of premium on the sale of the balance of preference shares disposed of since 1st January, 1883. Messrs. Bannatyne and Etlinger are the directors retiring by rotation, and being eligible, offer themselves for re-election. Mr. Herbert R. Duke is eligible as auditor for the present year.

## NOTES.

THE UNITED TELEPHONE COMPANY'S BILL.—The Westminster District Board of Works have petitioned against this Bill.

SUNSPOTS.—*Longman's Magazine* for April contains an article from the pen of Mr. R. A. Proctor, on "A New Theory of Sunspots."

ELECTRIC LIGHTING IN BRISBANE.—The *Colonies and India* says that it is expected the Parliament Houses will be lighted by means of electricity next session.

GERMAN UNION TELEGRAPH COMPANY.—The directors of this company announce a final dividend of 6s. per share in respect of the year 1883, making a total distribution of 11s. 9d. per share.

UNDERGROUND WIRES IN MONTREAL.—A system of underground wires is now being tried in Montreal. Ten wires have actually being laid, two of which are being tried in connection with the city fire service.

MILITARY TELEGRAPHISTS.—We are informed that it is contemplated to add considerably to the number of telegraph signallers in the Army Reserve. The men will be selected from the Post Office volunteers.

ELECTRICAL EXHIBITION AT PHILADELPHIA.—Progress is being made with the buildings for this exhibition, which is to be held at Philadelphia in the autumn of this year under the auspices of the Franklin Institute.

EARTHQUAKE AT SAN FRANCISCO.—Telegrams to the daily papers state that two shocks of earthquake were experienced at San Francisco on Tuesday afternoon, several buildings standing on ground near the water being damaged.

FRENCH ELECTRICAL POWER STORAGE COMPANY.—A petition for the winding up of this company was presented on the 14th inst. by Messrs. Woodhouse and Rawson, of 11, Queen Victoria-street, E.C., and will be heard before Vice-Chancellor Bacon to-day (Saturday).

TELEGRAPHIC EXTENSIONS.—The Royal Engineers are engaged in fixing several additional telegraph wires along the route between London and Bristol, and a new telegraph service is to be established between the metropolis and Exeter *viâ* Basingstoke and Salisbury Plain.

LANCASHIRE MAXIM-WESTON COMPANY.—The creditors of this company should send their names and addresses, with particulars of their claims, before the 9th April to Messrs. T. Whitworth and J. Brown, of 17, Warwick-street, Regent-street, W., the liquidators.

WEST INDIA AND PANAMA TELEGRAPH COMPANY.—The estimated traffic receipts of this company for the half-month ended March 15 are £2,765, as compared with £4,339 in the corresponding period of 1883. The December receipts, estimated at £4,466, realised £4,565.

THE HEALTH EXHIBITION.—We are informed that the Commissioners of the International Health Exhibition, South Kensington, have contracted with Henley's Telegraph Works Company for the supply of all electric light cable they require for the purposes of the exhibition. Their patent ozokerited India rubber insulation will be used.

ROYAL COMMISSION ON ACCIDENTS IN MINES.—According to a statement made by Sir W. Harcourt in the House of Commons a few days since, the draft of the final report of this commission has been prepared. Their investigations have extended over five years. It is hoped that the report itself will be presented before the end of the present session.

PRIVATE HOUSE LIGHTING.—The contract for the lighting of Astley Bank, the private residence of Mr. D. P. Huntington, has been placed in the hands of Mr. F. D. A. Goold, electrical engineer and contractor, of 29, Arcade-chambers, St. Mary's Gate, Manchester. The plant will consist of 100 60-volt incandescent lamps, the current for which will be derived from a "Victoria" dynamo of the latest pattern, which will be driven by one of Messrs. Crossley's "Otto" gas engines.

ELECTRIC LIGHTS FOR LIGHTHOUSES.—The French Government has given notice that it is intended shortly to substitute electric lights in the lighthouse on Touquet Point at the south side of the Canche River entrance for those already in use. The works in connection with this alteration will be commenced on the 1st April next. The electric lights will be flashing lights, with white flashes every four seconds, visible in clear weather from a distance of about nineteen miles; they will be exhibited about 15th July, 1884.

ELECTRIC LIGHTING AT DEAL.—A company has been formed under the title of the Deal and Walmer Electric Light Company to supply electricity for public and private purposes in these towns. We should have thought that company mongering, so far as electricity was concerned, was at a discount. Electric lighting has not prospered in the hands of companies, whatever some of them may have made of the manufacturing part of the business. So we hope that the towns above-mentioned will prove a deal too canny to be taken in and done for, though we should be glad enough to see legitimate business done there.

CHESS BY TELEPHONE.—A match by telephone between the Cardiff and County and the Swansea Chess Clubs was played a few days since, and resulted in a victory for Cardiff. The match excited considerable interest among local chess-players, and there was a large attendance of members of the Cardiff Club at the office (kindly lent for the occasion) of Messrs. Poingdestre and Mesnier, James-street, Docks. The postal authorities, through the kindness of Mr. Gavey, superintending engineer of the South Wales district, gratuitously placed the telephone between the two towns at the disposal of the clubs, and did everything possible to make the match a success.

ELECTRIC LIGHTING IN POLAND.—A correspondent of the *Bulletin* de la Compagnie Internationale des Téléphones writes that the electric light has been introduced into the spinning mill of Messrs. Leon Allart and Co., at Lodz, Government of Petrokow, Poland. This mill has an area of 5,000 square metres, and is lighted by 40 arc lamps, the invention of M. Gravier, of Varsovia, to which are to be added shortly 25 others, as well as 20 incandescent lamps. The cost of the lighting is put at 3 roubles, 21 per hour for the 40 lamps, one lamp costing, therefore, 8 copecks, or 20 centimes. Each lamp is said to be of 400 candle-power, or 50 carcels (the French standard).

PICKING AND STEALING.—The *Electrical Review* (New York) makes some invidious remarks in its issue of 13th inst. concerning two English journals which it names, and one which it does not name, but accuses it of picking and stealing. Speaking for ourselves, we have no fault to find with its ideas of picking, seeing that it has the good taste to pick from our columns, frequently and without stint. But its ideas of stealing must be peculiar, for the very number in which the accusation is made contains no fewer than four notes or translations,

Digitized by Google

copied word for word from our pages, without once acknowledging *The Electrician*. In England we call this stealing. What do they call it in America?

THE TELEPHONE IN BRADFORD.—In October, 1880, the National Telephone Company opened their exchange at Bradford with half-a-dozen subscribers, the calls at that date being about twenty-three per diem. Now there are 280 subscribers, and the calls per day reach 1,996 on the average. To show the rate of rise we may mention that in April, 1882, there were 135 subscribers, and the average calls per subscriber per day were 2·11. In April, 1883, the subscribers had increased to 224, and the average calls per day to 4·08. Now, as will be seen above, this average has risen to 7·12 for each subscriber per diem. The company have replaced all their heavy iron wires with phosphor bronze wire, which is much lighter and less likely to break.

MR. FAWCETT AND THE POST OFFICE STAFF.—On Wednesday night a *conversazione* in connection with the East London Postal and Telegraph *Employés* Circulating Library and Institute was held in the Victoria Hall, Victoria Park, E., the Postmaster-General being present. The institution has been established for the purpose of providing the postal and telegraph *employés* of the East London districts with a constant supply of good literature, and for promoting their rational recreation, mental, moral, and social improvement. In the course of the evening Mr. Fawcett addressed those present, and expressed his pleasure at the progress made by the society and its prosperity. He hoped it would continue to prosper in the future, and extend its sphere of usefulness.

GAS EXPLOSIONS.—We have had quite a number of explosions of gas of late. One, that in Paris, resulted in several deaths, and severe injuries to those who escaped with their lives. The others have all been accompanied by considerable destruction of property and more or less personal injury. From a letter, the pith of which we published in these columns last week, it appears that an incandescent lamp will explode—the record of such explosions is a remarkably small one—with the result that some one is rather frightened. We presume that most folks would rather receive a small shock—of fright—(though there are those who say they would rather be killed than frightened, an opinion chiefly confined to the fair sex, we believe) than be blown to bits without the option of being frightened instead.

SCINTILLATION.—In an interesting article in last week's *Knowledge*, describing the scintillometer, designed by M. Montigny, Professor at the Brussels Athenæum, and his researches into the cause of scintillation, a Fellow of the Royal Astronomical Society says:—"The stars twinkle most in January and February, and are most quiescent in June and July. The approach of rain and gales is heralded by an alteration in the scintillation; and it is much affected by the aurora. Hence it will be seen that the scintillometer furnishes us with a means of predicting coming atmospheric changes with considerable accuracy. One of the most remarkable results, however, at which M. Montigny has recently arrived is, that magnetic storms and violent scintillation are absolutely coincindent in point of time, a result which seems to open out a new field of investigation."

THE PRODUCTION OF HYDROGEN.—In a recent number of *La Nature* the expensive nature of the process of producing hydrogen by the decomposition of acidulated water by means of dynamos is pointed out. Our contemporary shows that with a perfect dynamo and perfect voltameter—things which, it is unnecessary to say, do not exist—the horse-power expended in the dynamo will decompose 166 grammes of water in an hour, and set free 18·5 grammes of hydrogen, measuring 296 litres, which are equal to 7·27 cubic feet. But our dynamos and voltameters are not perfect. Therefore, says our contemporary, if we suppose that the useful effect in the voltameter represents 70 per cent. of the total energy, 1 horse-power will set free in an hour 13 grammes of hydrogen, measuring 146 litres. To produce a cubic metre of hydrogen by this means would therefore require nearly 7 horse-power, or, to go further, it would take 200 horse-power to produce 1,000 cubic feet of hydrogen.

ARCHITECTS AND THE ELECTRIC LIGHT.—At a recent meeting of the Architectural Association Mr. Hampden W. Pratt read a paper on "Shams," in which he pointed out the variety of impostures that have arisen in architecture. Towards the end of his rather caustic paper Mr. Pratt said:—"With the general adoption of the electric light we shall be called upon to consider the appropriateness of fittings for it. We are too conservative in this respect, I think; there is too much resemblance, for instance, between the fittings used for candles, gas, and the electric light, and imitations easily creep in. An example of what I mean you will find in the Arbitration Room in this building, where the gas in the chandelier passes through imitation candles—a very senseless contrivance, I think. I do not know who admires such things; I should not think architects do; and yet this particular chandelier is placed in a room mostly used by such. But probably you will not attach much importance to that, for you will no doubt agree with me that the ventilation of this room is a sham, and if we were anybody else than architects I expect we should have called for or applied a remedy by this time."

ELECTRIC LIGHTING IN BRUSSELS.—A Brussels correspondent writes that the Belgian Government have placed the new Palais des Beaux Arts at the disposal of the Fédération des Sociétés d'Harmonie for the organisation of charity *fêtes* there. The occasion has been taken advantage of to light this vast building with electric lights, the work having been carried out by the Compagnie Générale d'Electricité. The necessary power is provided by means of five locomotives, aggregating 80 horse-power between them. Four self-exciting Gramme machines supply the necessary current to several Jablochkoff lamps, eight Grammes of the ordinary type, giving a current of 24 amperes, feed Jaspar lamps. Each of these machines will require three horse-power; and, finally, two Gramme machines are used to supply current to two groups of Edison 16 candle-power lamps, each group comprising 75 lamps. The grand concert-hall, which is 120 metres long and 40 wide, is lighted by five Jaspar lamps suspended high up. The corridors of the Exhibition of Industrial Arts are lighted by 40 Jablochkoff lamps. The large room in which flowers and plants are exhibited is lighted by Edison lamps, whilst Jablochkoff lamps illuminate the vestibule and staircases. The work has been rapidly carried out under the able superintendence of M. Nothomb, and the preliminary trials were all that could be wished. A Somzee secondary battery, with an incandescent lamp fitted on it, is used to inspect the machines, cut-outs, &c., whilst another battery of the same type is placed in the circuit of the machines and acts as a regulator.

ELECTROLYSIS OF SODIUM CHLORIDE.—In the *Gazzetta*, Vol. 13, pp. 279-80, Signor E. Rotondi gives the results of his experiments in this direction. We take the following abstract of his article on the subject from the *Journal* of the Chemical Society for March:—"The author's first experiments were made with a glass cylinder closed at bottom with parchment

Digitized by Google

paper, and placed within a glass jar, both vessels containing a saturated solution of sodium chloride. On passing a current through the liquid, the positive pole of the battery being placed in the inner vessel, chlorine was there evolved, and hydrogen in the outer vessel, where also sodium hydroxide was formed, which was subsequently converted into carbonate by a stream of carbonic anhydride. In other experiments the inner vessel was made of porous earthenware—in others again of poplar wood. By these means solutions of sodium carbonate were formed, equal in strength to those obtained by Leblanc's process. In all the experiments, however, free chlorine was detected after a certain time in the inner vessel, its presence there being due to an alteration in the diaphragm. To avoid this inconvenience, the inner vessel was filled with distilled water, and the outer with a solution of sodium chloride, which was kept constantly saturated. With this arrangement, the chlorine separated at the anode, being insoluble in the saturated solution, was evolved in the free state, and thus the alteration of the diaphragm and the formation of chlorinated compounds were avoided. The electrolysis of sodium chloride in this manner may be utilised in several branches of industry, as in the bleaching of vegetable fibres, in calico printing, &c., since by the expenditure of a moderate amount of mechanical power to generate the electric current a powerful bleaching and oxidising agent may be obtained, together with caustic or carbonated alkali."

THE ELECTRIC LIGHT IN MANCHESTER.—The story of the cessation of the electric light at the Royal Exchange, Manchester, was told last week at the annual meeting of the proprietors, by the chairman, Mr. J. Jardine. He said it had been a great disappointment to the directors, as it must also have been to the subscribers, that the electric light had disappeared, and at a time when it was perhaps most important that they should have a good light—in the shortest days of winter. He might tell them, as some justification of the directors, that they entered into an arrangement with the British Electric Light Company some two years ago. The company undertook the sole responsibility of supplying the light at a cost not exceeding the price which the directors had previously been paying for gas. The directors scarcely expected that the company would be able to supply the Exchange on such terms as these, because the electric light was what might be termed in its infancy. It was anticipated that the outlay to the company would be about £1,000, but it turned out to be something like £3,000; and no sooner had the light been brought to that condition when they could look upon it with some satisfaction than they received notice from the company to terminate the agreement. The directors were anxious to retain the electric light if possible; and a correspondence was opened with the company, in which a proposition was made to pay them double the price previously fixed upon if they would continue to supply the light. The directors were, however, met with the statement from the company that they were not prepared to carry on the lighting of the Exchange even on these terms, but that they would hand over the plant; and at the same time the company gave figures showing that the cost of producing the light was something like six or seven times more than that of gas. The directors could not, of course, undertake the responsibility of the plant and engines which had been put down, and applying the light themselves; and, in the meantime, the plant was lying idle in the basement of the Exchange. What use would be made of it, or what would become of it, he did not know.

CENTRAL NEWS v. EASTERN TELEGRAPH COMPANY AND OTHERS.—This case, which has already been referred to in our columns, *vide* our issue of the 8th inst., came up again before the Lord Chief Justice and Mr. Justice Cave on Wednesday. It was an appeal by the plaintiffs from an order of Mr. Justice Field, at Chambers, disallowing the inspection of certain documents to be used at the trial of this action, which has been brought by the Central News against the Eastern Telegraph Company, for having divulged the news of the fall of Tel-el-Kebir, transmitted by the correspondent of the Central News through the defendants' wires from Port Said, by reason of which this intelligence was anticipated in London, where it was circulated amongst the clubs and throughout the country, by about forty minutes in time, whereby the plaintiffs had lost the advantage that would have accrued to them had they been the first to afford public information on the subject. The defendants denied the disclosure as alleged, and an application was then made that they should allow an inspection of documents in respect of which interrogatories were put to them. To these they answered that they had only sent out three telegrams in cipher, which were wholly unintelligible to them, and which were delivered to them an hour and a half before the telegram alleged to have been divulged had been handed in, and further that these cipher telegrams did not go to England, but were stopped at Alexandria.—Mr. Justice Field held that the plaintiffs had no right to inspect the documents—firstly, on the ground that they were immaterial to the issue; and, secondly, that they were privileged.—Mr. Waddy, Q.C. (with Mr. C. Dodd), appeared for the plaintiffs in support of their appeal, urging that it was vital to their case to show that their message was the first received from the field of battle, and that, therefore, it was most material to them to see these cipher telegrams.—Mr. Moulton, on the other side, on behalf of the defendants, urged that it was clear that these cipher telegrams were irrelevant to the question, as they were stopped at Alexandria and not sent on to England at all, so they could not have included the message supposed to have been sent on in front of the plaintiffs'.—Lord Coleridge, after full discussion, said the defendants alleged in their affidavit that these cipher telegrams were irrelevant, and gave reasons showing that they were so. The case for the plaintiffs was that a message to them from their correspondent of the victory of Tel-el-Kebir was stopped by the defendants at Alexandria, and that the defendants having in some way got at its contents telegraphed a message to England in anticipation of the plaintiffs', which was delayed for about an hour. It was essential to this case that the message thus supposed to have been sent in anticipation of the plaintiffs' was one sent after the plaintiffs' was received (and indeed taken from it); and it was essential to the relevancy of these cipher telegrams that they should have been so received and sent. But these cipher telegrams, according to the affidavits, were received prior to the arrival of the plaintiffs' message, and, moreover, they were never sent on from Alexandria, but were delivered there, so that they could not have been the means or instruments of the alleged fraud upon the plaintiffs, and therefore must be irrelevant. The plaintiffs, according to the authorities, were bound by the oath of the defendants on that point, and that being so, the decision of the learned judge at Chambers in refusing to make an order for the production of these telegrams was right and must be affirmed, and the appeal dismissed with costs.—Mr. Justice Cave concurred, and the appeal was dismissed.

THE TELEGRAPH IN CHINA.—The following amusing and instructive account of the erection of land lines in China is given in the *Daily News* of the 26th inst. by their correspondent, who writes from Haiphong under date Feb. 15. He

Digitized by Google

says:—"The wisest expenditure of money which has been forced upon the Chinese Government by the French difficulty, and which is likely to prove permanently beneficial to the country in many ways, is the construction of the telegraph. Shanghai has thus been connected with Pekin, and Hong Kong with Canton. The Chinese Government is now engaged in constructing a line of telegraph from Canton to the borders of Tonquin, crossing the two provinces of Kwang-tung and Kwang-si. A good deal of opposition was experienced in making the Hong Kong-Canton line; the wires were torn down, the posts pulled up, and the men engaged in the work of construction were repeatedly driven away by the mob. Similar or even more determined opposition was anticipated in connection with the works now in progress, for the people of these two provinces are noted for their bitter antipathy to foreigners and foreign inventions. It is, moreover, popularly believed that the telegraph must seriously interfere with the good luck of the land it crosses. The Government, however, caused numerous placards to be previously posted in all the towns and villages through or near which the line of telegraph would pass, informing the people of its value to the Emperor in the difficulties which had arisen, and strictly charging them not to interfere in any way with its construction. A band of about 100 soldiers are engaged in the work under the superintendence of three Danish engineers; and as yet no opposition whatever has been met with. The work, however, is proceeding slowly; it was commenced upwards of a month ago, and has but just reached the first city in the province of Kwang-si; it will take a month or five weeks longer to complete the line to the Tonquin frontier. It is not at all surprising that the telegraph should be a source of continual wonder to a people so ignorant of science as are the Chinese. Little knots of people may frequently be seen gathered round a post listening with gaping astonishment, but with the fullest confidence, to some wiseacre who is pretending to explain the *modus operandi*. He tells them that there is a devil in each post, that the posts are placed close enough together for the devil in one post to make himself heard by the devil in the next, that the wire is placed on the top of the posts merely to keep them in an upright position; anything of a slant would make the devil inside feel very uncomfortable. These devils, of course, speak a language which is both unintelligible and inaudible to the uninitiated; 'foreign devils,' however, understand it well, and so to send a message is a very simple thing. A 'foreign devil' speaks it to the devil in the first post, he passes it on to the next, and so it reaches its destination, where another 'foreign devil' receives and interprets it. Other explanations are sometimes given, but all of them are equally wide of the mark. In any other country the construction of a line of telegraph would not be considered by the outside world a particularly important incident, but in China such an event is to those foreigners who know the country one of great importance. It not only brings the interior of China into direct communication with the other countries of the world, but it breaks the spell of that necromancy which has done so much to prevent the progress of the people; it throws a gleam of light upon that world of science of whose existence the people have been not only content but proud to remain in ignorance; it is a sign that the country is beginning to awake from that trance, like Conservatism, in which it has slept for ages; and so the telegraph in China cannot but be regarded as the forerunner of those arts and sciences, that higher learning, that truer civilisation, which must before long break down the mouldering barriers of China's isolation and unite her to the brotherhood of Christian nations."

Preventing Corrosion and Scale in Boilers.—A paper on this subject was read at a recent meeting of the Society of Arts by Mr. G. Swinburn King. After some preliminary remarks, Mr. King stated that it had long been suspected that "galvanic action or electricity in some form had to do with corrosion and pitting." He then mentions the various theories on the subject, and alludes to the numerous patent compounds for curing these evils, remarking that "some compounds cure one part of the evil, and do not touch others, while some, again, are extremely dangerous to use in a boiler under steam pressure." The author then refers to the results of the labours of committees appointed by the Admiralty between 1874 and 1880 to inquire into causes of decay in the boilers of H.M. ships. "The main conclusion," he says, "at which the committee arrived — the great principle that they asserted and demonstrated—was that galvanic action, induced by the contact of zinc with the iron of the boiler, was the best and only trustworthy remedy for corrosion; and that, so long as the metallic contact was maintained, little or no corrosion would go on. They adopted a plan of hanging slabs or plates of zinc by iron straps from the slags or rods within the boiler, the zinc being held in a clip in which it was tightly bolted. The theory was perfect, but the weak point in practice was found to be in keeping up electric contact between the two metals. The committee endeavoured to circumvent this difficulty—first by fixing in each boiler an excessive number of plates, so that, apparently, if electric contact should cease even in many plates it might chance to be maintained in some; and, secondly, they directed a frequent examination with the view of renewing the contact and putting in fresh plates in lieu of those destroyed by corrosion. This system was the best they were able to arrive at, but it could be maintained only at such a cost that, to use the words of the report, 'the expense of the zinc necessary for efficient protection is undoubtedly an important element in determining how far it should be adopted.'" (It appears that the actual waste of zinc was much greater than that due to the protection of the boiler.) The author then describes a number of experiments, all of which failed from the same cause, viz., destruction of the metallic contact between the zinc and iron from one cause or another. To remedy this, Mr. Hannay, an electrician, of Glasgow, designed what he calls an "electrogen," composed as follows (we quote from Mr. King's paper):—"A ball of zinc, with a copper conductor cast through the centre of it, the copper being so combined and amalgamated with the zinc at the junction of the two metals as to form brass. Thus no corrosion could form between them to stop the galvanic current. The zinc is well hammered at a certain temperature, ensuring long existence in an efficient condition. This ball is fitted in any convenient part of the boiler by a simple device, and a wire from each end of the copper conductor is soldered firmly to the iron. From this moment the electrogen keeps up an uninterrupted galvanic current, and the whole of the interior of the boiler is absolutely protected from corrosion so long as any of the zinc remains. It was ascertained, by further experiments, that a very small surface of zinc was sufficient to afford protection for a radius of twenty-five feet from the point of contact, and the spherical form of the zinc was adopted because it would maintain perfect protection with a minimum of waste, the large surface exposed by plates, in proportion to their bulk, being quite unnecessary. Herein, therefore, was the means of avoiding that waste which the Admiralty Committee stated was 'much greater than that due to the protection of the boiler,' and for which they sought a remedy. Two electrogens are found in

Digitized by Google

practice sufficient to protect an ordinary 'single-ended' marine boiler in which, by some engineers, forty or fifty plates would have been considered necessary. The electrogens will last for about six months, while the plates would probably corrode away in as many weeks. The zinc ball, with its perfect contact, generates a current of greater intensity than zinc plates mechanically fitted, and the consequence is that a portion of the water is slowly decomposed, and the hydrogen that is evolved at the negative pole, all over the surface of the iron and underneath the scale, forces off the scale in thin flakes by mechanical action as soon as it becomes thick enough to be impervious to the hydrogen. In this way the scale is kept forming and re-forming, hanging in loose flakes, or falling off as it becomes detached from the iron. Thus all the evils attending incrustation, which have been before enumerated, are avoided. Fuel is saved, burning of the iron is prevented, and chipping becomes no longer necessary."

THE TELEPHONE FOR PORTSMOUTH.—On Thursday, the 20th inst., a special meeting of the members of the Portsmouth Chamber of Commerce was held at Landport, to receive a reply to the deputation which recently waited on the Postmaster-General on the subject of a telephone exchange for that town. The deputation, it will be remembered, asked that Portsmouth might be placed on the same footing as Liverpool, Bristol, and Birmingham, and made rather invidious comparisons between the telephone system as supplied by the Post Office and the United Telephone Company. A report of the proceedings and Mr. Fawcett's reply will be found in our issue of the 23rd Feb., p. 341. Mr. Alderman King, a member of the deputation, gave an account of their reception at the hands of the Postmaster-General, and said that the latter had written a long letter to the Hon. T. C. Bruce, M.P., one of the members for Portsmouth, who introduced the deputation, in which he dealt with the various arguments advanced by them. There were two points on which the deputation thought that the Post Office would not be able to meet the wishes of the public in Portsmouth and the neighbouring towns. These were (1) an all-night service, and (2) the establishment of local exchanges in each of the four towns, so that all subscribers might be within a radius of one mile from their exchange, and be relieved of the necessity of paying for lines of greater length than one mile. On these points Mr. Fawcett wrote :—"I have carefully considered what was said by the deputation, and I think there will be no difficulty in arranging for attention to be given at night in the event of an exchange being established by the Post Office. I suppose it would only be on rare occasions that the subscribers would wish to speak to each other late at night, and it would not pay to keep an officer in constant attendance at night in the switch room of the exchange; but there is some one always in attendance in the sorting office, and we might arrange to have a bell fixed in the sorting office, so that when any one wished to use the exchange this bell might be rung, and an officer would then go at once to the switch room and attend to the call. This is an arrangement which we have already made at some other places, and it is found to work satisfactorily. As to the establishment of a separate exchange centre for each town, I may say that I do not think this would be in any way to the advantage of the public. A more efficient and expeditious service could be given by leading all the wires into one central exchange. If the wire were led into one exchange there would be only one operation of switching through when a subscriber wished to speak to another subscriber; but, if four separate exchanges were established, there would always be two operations of switching through when a subscriber in one town wished to speak with a subscriber in another. Thus, if a subscriber in Southsea desired to speak with one in Portsmouth he would have to call up the Southsea Exchange, that exchange would have to switch him through to the Portsmouth Exchange, and there again he would have to be switched through to his correspondent. There would therefore be a switching operation at two exchanges instead of only at one. Not only so, but as the two exchanges would probably be connected by means of only a single wire, and as this wire would often be occupied, the subscriber might have to wait before he could get through to his correspondent at Portsmouth. What the department would propose, if the people in Portsmouth were desirous that it should establish a telephone exchange, would be to have one centre, and to carry the whole of the wires into that centre. In this way there would only be one operation of switching when a subscriber wishes to speak to another subscriber, and there would be no waiting for turn on a connecting wire between two exchanges. The question whether the department would have to charge more in any case than the rate for a single mile has been carefully considered, and I have come to the conclusion that a point might be selected from which a circle of one mile could be described to take in the whole of the business portions of the four towns. It would not, therefore, be necessary to charge a higher rate than for one mile in the case of any of the business men in the four towns. In view of the growing objections to over-house wires, I think that the department, if it established a telephone exchange system in Portsmouth, ought to place the whole of the main lines underground; and, to secure secrecy in the working of the exchange, and greater efficiency, I think that double wires ought to be used. If so, the charges of the department would be as follow:—For one mile, £21 10s.; for three-quarters, £19; for half, £16 5s.; for quarter and under, £14 10s. These charges include not only payment for the use of the exchange system, but also payment for clerks at the post office to take messages intended to be transmitted over the public wires, and for sending to subscribers messages which arrive over the public wires." Some discussion ensued on the reading of this letter, and eventually it was resolved to appoint a special committee to consider the matter and reply to the Postmaster-General's letter. This committee met on the day following the meeting (Friday, the 21st inst.), and drafted a letter, in which they stated that the rates quoted by Mr. Fawcett were prohibitory, and such as would prevent a successful exchange being established in Portsmouth. They suggested that it would be more equitable to strike a radius of the business centre of the towns, and charge a uniform rate to all within that radius, because it scarcely seemed reasonable that the accident which placed the department's chosen centre near a particular subscriber should give him the advantage of price, because although he had the exclusive use of the shorter wire he had the general use of all longer wires, for which other subscribers would have to pay. They also felt that the differential charge would deter many from joining the exchange, because it might frequently happen that the subscribers at the longest distance from the centre would be the people who would derive less advantage than the other subscribers who happened to be close to the centre. Finally, if their views met with Mr. Fawcett's concurrence, the committee would like to know the lowest figure at which he would give the uniform rate, say within a mile radius from a centre which embraced the business parts of the four towns. The committee were of opinion that a price more than £15 would not secure sufficient subscribers to make the exchange a success.

## ELECTRO-CHEMISTRY.—INORGANIC.

BY DR. G. GORE, F.R.S.

(CONTINUED FROM PAGE 439.)

**Electrolysis of Argentic Chloride.** Ag.Cl. Molecular weight = 143·5. Aluminium evolves great heat by contact with melted argentic chloride, and separates the silver in melted globules. It also precipitates silver as a fine crystalline powder from an ammoniacal solution of the chloride (A. Cossa, Watts's "Dictionary of Chemistry," Vol. VI., p. 54). Fused argentic chloride is resolved by the current into silver at the cathode, and chlorine at the anode (Faraday). Sodium amalgam reduces the chloride, bromide, and iodide of silver, when in contact with water.

**Electrolysis of Argentic Chlorate.**—Ag. $ClO_3$. Molecular weight = 191·5. A solution of this salt containing free chloric acid was easily decomposed by a current from two Smee cells, with a silver anode. It yielded a copious deposit of loose silver upon the cathode, and upon the anode a black crust, apparently of argentic peroxide, which soon stopped the current. To electrolyse it properly requires a feeble current, a large cathode, and a very large anode (See *Proceedings* Birmingham Philosophical Society, Vol. IV., part. 1).

**Electrolysis of Silver Perchlorate.**—A solution of argentic perchlorate, containing free perchloric acid, with a silver anode, is a remarkably good conductor. It conducted copiously a current from a single Smee element, and was decomposed even more readily than the chlorate. The anode was rapidly corroded, and acquired, first, a thick loose coating of black solid matter, and then one of a dark green colour. To electrolyse this liquid properly requires a very feeble current, a rather small anode, and a very large cathode. (See *Proceedings* Birmingham Philosophical Society, Vol. IV., part 1).

**Electrolysis of Argento-sodic Sulphite.**—An aqueous solution of this salt is said by Roseleur to possess a singular property. When a piece of metal is immersed in a solution of another one, in which it coats itself with that metal, a portion of the immersed one dissolves, and produces an immense number of minute electric currents which pass from an infinity of minute portions of the surface of the metal into the liquid, decomposing it, and re-enter at other minute portions of the metallic surfaces, and deposit an equivalent weight of the other metal as a coating upon the immersed one; but in this particular solution a spontaneous *chemical* change also occurs in the liquid itself, the sulphurous anhydride of the argentic sulphite takes oxygen to itself to form sulphuric anhydride, and sets the silver free, and this silver adheres to any solid surfaces present, *i.e.*, to the immersed metal, and to the containing vessel. The sulphuric anhydride unites with some of the soda of the undecomposed portion of the sulphite, and liberates sulphurous anhydride, and forms sulphate and bi-sulphite of sodium. This action is very similar to that which takes place in certain processes of coating looking-glasses with pure silver.

A solution also composed of sulphite of silver dissolved in an aqueous solution of potassic sulphite has been used for depositing silver by the separate current process. It is a very good one except that it gradually decomposes and deposits its silver by the influence of light. A solution has also been formed by dissolving argentic chloride in an aqueous solution of sodic hyposulphite. It easily yields its metal by electrolysis with a current, but under the influence of light it is decomposed, and its silver precipitated as argentic sulphide.

**Electrolysis of Argentic Sulphate.**—Aq. $SO_4$. Molecular weight = 204. In an aqueous solution of the sulphate of silver, antimony, tin, iron, copper, and the alloys of silver with zinc, tin, or lead, deposited the silver by simple immersion, but bismuth did not.

**Electrolysis of Argento-potassic Cyanide.**—Ag. Cy. KCy. Molecular weight = 199·1. A solution of this salt, containing an excess of potassic cyanide, constitutes the ordinary silver-plating liquid. It may be formed by dissolving the salt in water, say, one or two ounces per gallon—the exact proportion is not material—and then adding about one-tenth of its weight of potassic cyanide. Nearly the same mixture is obtained by electrolysing a solution of potassic cyanide with a silver anode, until silver is freely deposited; in this case, however, caustic potash is formed in the liquid, and gradually becomes converted into carbonate by contact with the air. Electrolysis of the solution yields silver alone at the cathode, and at the anode argentic cyanide, which dissolves. A number of modifications of this liquid have been employed, such as solutions formed by dissolving nitrate, chloride, or ferro-cyanide of silver in one of potassic cyanide, but the above mixture is the best.

By dissolving some bisulphide of carbon in a strong solution of potassic cyanide, and adding *a very minute proportion* of this solution occasionally to the above mixture, the physical character of the deposited silver is greatly changed; instead of being soft and somewhat dull white in appearance, it becomes hard and highly lustrous, like burnished metal. I have found by chemical analysis that it contains a minute proportion of sulphur.

By electrolysing a 33 per cent. aqueous solution of methylamine with a silver anode and a feeble current from a single Smee's cell, the anode slowly dissolved, and a loose deposit of silver crystals formed upon the cathode. Somewhat similar results were obtained with a strong solution of trimethylamine.

Blagden states that the desilvering of lead is facilitated by dissolving about half a per cent. of zinc in the refined metal at 540° C, and passing a voltaic current through it by means of copper wires, until all the zinc has risen to the surface! This crust contains the silver, and may be removed after the melted mass has fallen to 450°. The process must be repeated several times.

For a solution fit for silvering iron, see Watts's "Dictionary of Chemistry," Vol. VIII. part 2 p. 1,119. For deposition of silver from a pasty mixture of salts by simple contact, *see* Roseleur *Jour. Chem. Soc.*, Vol. 34, 1878, p. 538. For the electrolytic analysis of silver, see *Chem. News*, Vol. XLII., p. 331 and p. 76. Watts's "Dictionary of Chemistry, Vol. VII., p. 790. *Jour. Chem. Soc.*, Vol. XXXVIII., 1880, p. 747.

**Separation of Mercury.**—Hg. Atomic weight = 200. A dyad cation. I have observed that solutions of mercurous salts have their metal deposited by simple immersion, by arsenic, antimony, bismuth, zinc, cadmium, tin, lead, iron, copper, brass, and the alloys of silver with zinc, tin, lead, or copper. Iron deposited mercury from a solution of mercury acetate. A. Cossa states that aluminium deposits mercury by simple immersion in aqueous solutions of mercuric nitrate, chloride, and cyanide; also from a solution of mercuric chloride in alcohol, and of mercuric iodide in one of potassic iodide. (Watts's "Dictionary of Chemistry," Vol. VII. p. 54). Thallium deposits mercury from an aqueous solution of mercurous sulphate (W. C. Reid, *Chem. News*, Vol. XII. p. 242). Solutions of salts of mercury have been electrolysed by the mutual contact of two metals in them (*see* Gladstone and Tribe's experiments, *Phil. Mag.*, 4th series, Vol. XLIX. p. 425.)

I have observed that by passing a current from a mercury anode through dilute sulphuric acid into a platinum cathode the latter soon acquires a coating of mercury. E. Obach states that a liquid alloy of sodium and mercury showed no signs of electrolysis by passing through it an electric current.

**Electrolysis of Nitrate of Mercury.**—Copper immersed in a solution of nitrate of mercury deposits the latter, and forms an amalgam. By electrolysing a solution of cupric sulphate into a cathode of mercury a similar alloy is formed. An aqueous solution of mercuric nitrate has been used by electro-platers for "quicking" the surfaces of articles previous to plating them. A solution of nitrate of mercury yields its metal to bismuth, zinc, cadmium, lead, iron, or copper, but not to silver, gold, or platinum, by simple immersion.

**Electrolysis of Mercuric Chloride.**—$HgCl_2$. Molecular weight = 271. From an aqueous solution of this salt magnesium deposits mercuric oxide and calomel (Commaille, *Chem. News*, Vol. XIV., p. 188).

A solution of mercuric chloride, slightly acidulated with sulphuric acid, in a platinum vessel cathode, was electrolysed, and the amount of mercury in it determined by means of a current from six Bunsen cells, the anode being a sheet of

Digitized by Google

platinum. Mercurous chloride was first deposited, but at the end of one hour all the salt was reduced to mercury so perfectly that the supernatant liquid was not rendered cloudy by addition of ammonia. By running a stream of water finally through the vessel whilst the current was passing the whole of the mercury was obtained in a pure state (F. W. Clarke, *Report of the Chemical Society of Berlin*, No. 12, 1878). Gladstone and Tribe noticed that when a weak current was passed through a solution of mercuric chloride into a cathode of platinum a film of mercurous chloride was deposited, but if the current was strong, metallic mercury was set free.

**Electrolysis of Potassio Mercuric Cyanide.** $2KCy.Hg.Cy_2$. Molecular weight = 382·2. The solution of this salt readily deposits its metal by simple immersion upon copper, and various of the base and alkali metals, and is therefore used by electro depositors to prepare, by the process termed "quicking," the surfaces of metal articles to receive an adherent deposit of silver. It also readily yields its metal by means of the other methods of electrolysis.

**Electrolytic Movements of Mercury.**—In consequence of being a liquid, mercury exhibits certain peculiar phenomena of motion and alteration of form when used as an electrode. This effect appears to be partly a consequence of a film of oxide or other salt formed upon it when it is an anode, and of hydrogen or other substance formed upon it when a cathode, and partly also of simple electrification. H. Herwig has observed that a drop of mercury placed on a glass plate, and strongly electrified by either pole of a Holtz machine, becomes flattened, and if the mercury is in a narrow glass tube its capillary depression is greatly diminished. The effect is greatest with the positive pole, probably in consequence of the higher tension of that pole. (*Pogg. Ann.* CLIX., p. 489—492.) As early as the year 1801, Gerboin noticed some of the electrolytic movements of the metal, and the phemomena have since been investigated by Sir H. Davy, Sir J. Herschel, Serullas, Erman, Runge, Poggendorff, Gmelin, and others. (*See* Gmelin's "Handbook of Chemistry," Vol. 1, p. 381—384). Also by T. S. Wright (*Phil. Mag.*, Vol. XIX., 1860, pp. 129—133), by R. Sabine (*Phil. Mag.* [5], Vol. II., p. 481), and Th. du Moncel (Watts's "Dictionary of Chemistry," Vol. VIII., part 1, p. 714). The movements have also been applied by Lippmann to the measurement of extremely feeble electric polarities in his capillary electroscope; and also to the production of motion in his capillary electric engine. In most of these cases the electrolyte employed was dilute sulphuric acid.

(TO BE CONTINUED.)

## CURRENT ENERGY.—XV.

BY OLIVER HEAVISIDE.

(CONTINUED FROM PAGE 368.)

(*d*) Now, with respect to the hypothesis (*d*) of electric layers, widely believed in as realities, we shall endeavour to show that they are myths—that they cannot exist without violating principles where truth is as far as possible removed from being doubtful as anything can be in electrical science. We have already briefly described their supposed distribution in the case of E.M.F. acting at a surface, or through a stratum of small thickness. On one side of the stratum, that *to* which the force acts, there is supposed to be an accumulation of free positive electricity, and on the other side an accumulation of negative, which produce an electric field resembling that of a charged air condenser, whose force wholly cancels the contact force when there is equilibrium, and partly cancels it when there is current. The surface density of the accumulations must depend upon the thickness of the stratum, being great when it is small, and conversely.

If $t$ be the thickness of the stratum, and E the difference of potential, the electric force per unit length = $E/t$; hence, by the definition of the unit of electricity, applied to a surface distribution, the surface density is $\sigma = E/4\pi t$.

These electric layers are brought into great prominence when the E.M.F. acts all over a closed surface, for example, when zinc is immersed in air. To make the force quite uniform we may imagine E.M.F. to be applied at those places where it is supported equal to that acting from the zinc to the air. The electric layers will now form a pair of closed surfaces, very close together, wholly surrounding the conductor, the positive layer outside, the negative within. This combination we may call a closed electric shell, from its obvious similarity to the closed magnetic shell which appears in the theory of magnetism. The electric force of the shell is wholly self-contained, that is, it is situated between the two layers of electricity, directed straight across the stratum from one to the other, with no electric force either within the inner or outside the outer layer. The potentials are uniform inside and outside the shell, but differ by the amount E, if E is the E.M.F. from the zinc to the air. For if a unit charge of electricity be carried from inside the conductor to the external air, it will travel against the electric force of the accumulations, and work must be done on the charge to the amount force × distance, or $E/t \times t = E$, which is therefore the excess of the outer above the inner potential. In this we consider the electric force due to the layers alone, for the resultant force being nothing, no work would really have to be done.

Comparing with a closed magnetic shell, if its positive side be the outer, the outer magnetic potential exceeds the inner by $4\pi$ × strength of the shell. This conforms to the above, remembering that the "strength" of a simple magnetic shell is defined to be the magnetic moment of unit of area, and is therefore = surface density of magnetism × thickness of shell. We might similarly define the strength of the hypothetical electric shell, but it is not worth while doing so, as the amount of the difference of potential sufficiently settles it.

Now, these electric layers, if they existed, would be wholly independent of any real charge that we might communicate to the conductor. Say, for instance, we charge it by contact with some other metal. This will not alter the electric layers in any way. If they were there before, they are there still, for there is still the same difference of potential at the surface. The real charge, being connected by lines of force through the air with other conductors, is of course recognisable, but no tests can be applied to the associated layers. Perhaps it would be most reasonable, as it is simplest, to put the real charge outside the outer layer, rather than within the inner, or between them, if we must have the electric layers. But, although this extraordinary complication of the surface conditions by the presence of the layers may be used as an argument against their existence, still, such argument would be no proof that they do not or that they cannot exist. To obtain this in a plain form, it will be advantageous to both generalise and simplify. As often happens we lose nothing, and gain much by generalising, obtaining a broader view of a question freed from accidentals. The simplification of conditions again is desirable in order to separate the layers from the real charge, and exhibit them apart.

Let there be two wires of different metals and of the same gauge, whose ends are cut off straight across, and then their plane faces firmly pressed into one another to form a continuous wire. There is the Peltier contact force at this junction, and the electric layers corresponding must be very close together. There are also charges on the air surfaces of the two wires, due to the Peltier E.M.F., quite irrespective of the air E.M.F. and its layers. Now the layers do not depend on the special origin of the E.M.F. or upon the fact that the E.M.F is at a junction of two metals. Let us therefore increase the thickness of the stratum in which the E.M.F. acts, stretching it out until from a stratum it becomes a cylinder or tube of E.M.F. of any length. Also do away with the other restriction, and let this tube of E.M.F. exist in any given length of a wire of one metal. If the force is uniformly distributed throughout the given space, then, just as in the case of the thin stratum, there will be the accumulations of free electricity at the plane ends of the lines of E.M.F., whose surface density will be $e/4\pi$ and $-e/4\pi$ respectively, $e$ being the impressed E.M.F. per unit length. Next let the force be not uniformly distributed, but vary in intensity along the portion of wire considered, though still abruptly ceasing at the same places. We still have the terminal layers of course, but now in addi-

Digitized by Google

tion to them there must be a distribution of free electricity between them to correspond with the gradual variation of the force. The volume density of this latter distribution is to be found by the same principle as the terminal surface densities, by reckoning the excess of the number of lines of force, leaving over those entering a small space. In mathematical language, the volume density of the free electricity equals the convergence of the impressed force divided by $4\pi$; this corresponds to the just given statement of the density of the terminal accumulations.

Thus, in general, when any impressed E.M.F. acts in a wire, we have not merely current, if the wire forms a closed circuit and the sum of the impressed forces taken round the circuit be not zero, and the surface electrification depending on the distribution of potential, to be recognised by the electric force in the surrounding air, but also, according to Helmholtz's hypothesis of electric layers, an internal distribution of free electricity depending on the manner of distribution of the impressed force.

Now it may be objected that, although when a distribution of electric force is given in air we can always find the free electricity to correspond by the convergence of the force, yet to apply the same method to the interior of a conductor is not justifiable, a good conductor, as a metal, being so very different in its properties from air, in which electrostatic observations are made. Again, why not apply the method to the actual E.M.F. in the wire? the resultant of the impressed force and that arising from difference of potential. This application is quite correct in a dielectric. If there is no force, or if the force has no convergence within a given space in air, there is no free electricity there. Similarly in the conductor; should there be equilibrium, there is no resultant force and no free electricity; whilst, on the other hand, should there be current, the resultant force, which is proportional to the current, has, like the current, no convergence, so there is still no free electricity.

But the matter is reduced to the simplest form by doing away with the surface charges altogether, by sufficiently enlarging the conductor. Theoretically we may consider an infinitely large conductor; practically, one whose boundary is far removed from the seat of the impressed E.M.F. Let the conductivity of this large conductor be uniform, and let there be a certain portion of it (not insulated from the remainder) in the form of a thin rod along which impressed E.M.F. acts in the direction of its length. The positive "pole" being defined to be that end to which the impressed force acts, the current will flow along this tube of impressed force from the negative to the positive pole, and issuing there, will spread out in all directions, at first in straight lines radiating from the pole, but sooner or later bending round to enter the tube at the negative pole in a similar manner.

Here the contact layers will be represented by an accumulation of positive electricity at the positive pole, and of negative at the negative pole, where the current leaves and enters respectively; and since the boundary of the conductor is indefinitely removed, we have no surface charges to complicate the question. The only accumulations, if there be any, are those at the ends of the tube of impressed force, and the question arises, How did they get there? In the first place, they were certainly not there before the impressed force began to act, so they must have been set up whilst the current was being established, which does not happen instantaneously. Now this establishment of the current is a very complex matter, but we do not need to enter upon it here at all, for this reason: It is admitted that currents in conductors always flow in closed circuits, that across any section of a tube of current (the whole system being divided into tubes) the same amount of current flows. It is clear, then, that no further accumulations than the hypothetical ones can take place after the current becomes steady. But not only that, whatever may have been the nature of the distribution of the induction currents before the steady state was reached, such currents must have formed closed tubes, and this excludes the possibility of any accumulations taking place at any time in the interior of the conductor.

The accumulations depending on the convergence of the impressed force are thus wholly mythical; and since the electric layers in the case of contact force are a special case of the same, they, too, are mythical. At a metallic junction there is no double layer accompanying the Peltier force, and at an air or liquid surface there is no electric shell accompanying the E.M.F. from the metal to the air or the liquid, but only the charge to be determined by the distribution of electric force in the air surrounding the conductor.

*Impressed E.M.F. and Potential.*—In a galvanic circuit with steady current, the impressed force is confined to a certain part of the circuit, namely, portions of the battery, the force in the remainder of the circuit being derived from difference of potential. But in other cases we have distributed E.M.F.'s, as in thermo-electricity depending on the variation of temperature along a conductor, or in current induction; in both cases there is usually impressed force in every part of the circuit, as well as force derived from difference of potential, the actual force being their resultant.

To exhibit their general relation in the simplest manner, start with an infinitely-extended conductor of uniform conductivity, in which there is a given distribution of impressed force. The most general definition of impressed force is that depending on energy, as, in fact, all forces, simple or generalised, are expressed by energy variations. If E be the impressed force within a certain unit volume of the conductor, and there be a current of density C at that place, and in the same direction as E, then the amount of energy taken in per second within that unit volume by the current is represented by the product, $EC = W$, say. Should E and C be in opposite directions, though still parallel, there is corresponding energy given out by the current. Should E and C be perpendicular, there is no energy either taken in or given out. When E and C are inclined to one another at any angle (which is almost sure to be the case in a large conductor, since C does not depend on E only at the spot, but upon the impressed force at other places as well), then to find the energy taken in by the current we must multiply the product of E and C by the cosine of the angle between their directions, which we may represent by EC, using a notation which adapts itself conveniently to common algebra.

[If two numbers or algebraic quantities A,B, be each divided into any number of parts $A_1$, $A_2$, ..., $B_1$, $B_2$, ..., their product is the sum of the products of the components. Or

$$AB = A_1B_1 + A_2B_2 + A_1B_2 + A_2B_1 + \ldots \text{ to include all.}$$

Now, if A and B be vector quantities, as E.M.F. and current, and be similarly each the resultant of a number of separate E.M.F.'s and currents, the above algebraic equation holds good, with this modification, that every product be multiplied by the cosine of the angle between the directions of the two factors. Thus

$$\overline{AB} = A_1\overline{B_1} + \overline{A_2}\overline{B_2} + A_1\overline{B_2} + \overline{A_2}B_1 + \ldots \text{ to include all.}$$

Represented in ordinary Cartesian co-ordinates, we should have very long expressions.]

The frictional generation of heat is directly excluded. It is always a conversion *from* electrical energy *to* heat, and never the other way. Its amount is $\rho C^2$ per unit volume, if $\rho$ be the specific resistance. But the energy transformation concerned in impressed force is reversible with the current.

Given, then, a distribution of impressed force, E, throughout the conductor, we know that the whole amount of energy taken in per second is $\Sigma EC$, summed up to include every place where E exists. We also know by Joule's law that the total frictional heat $= \Sigma\rho C^2$. By conservation of energy these two sums must be equal. This implies some special relation between E and C. By Ohm's law $\rho C$ is the actual resultant force corresponding to the current C; let this $= E + e$, so that $e$ is the force that must be added to the impressed force at any place to make up the actual force. Then $\Sigma E\overline{C} = \Sigma\rho C^2 = \Sigma\rho C.C$, by putting $E + e$ for $\rho C$, becomes $\Sigma E\overline{C} = \Sigma E\overline{C} + \Sigma e\overline{C}$. Therefore $\Sigma e\overline{C}$ must vanish. Whatever be the impressed force, the supplementary force does no work upon the current on the whole. This characteristic will, with other considerations, serve to determine $e$.

Digitized by Google

There are two extreme cases of impressed force that mark themselves out distinctly. First, let the impressed force E be confined to a portion of the conductor forming a closed ring, the direction of E being along the ring, and its strength such that there is the same amount of E acting across every section of the ring. This is a closed tube of force. The current distribution follows immediately. If $k$ be the specific conductivity, the reciprocal of $\rho$, then $C = kE$ simply. For Ohm's law is satisfied everywhere, and the continuity of the current is ensured by the continuity of the impressed force. Thus the current is entirely confined to the closed tube of force, and has no tendency to spread around, although there is no insulation of the tube from the remainder of the conductor. Not only is $\Sigma EC = \Sigma\rho C^2$ or $\Sigma kE^2$ on the whole, but the same is true for every part of the tube. The energy taken in anywhere is exactly equal to the frictional heat in the same space, so that there is apparently no transfer of energy. We have supplied just sufficient impressed force at each place to support the current, with no excess or lack. Examples occur in electro-magnetic induction. The same applies to any number of closed tubes of impressed force, either wholly detached from one another or side by side in contact, and this includes the general case of any completely solenoidal distribution of impressed force, with the simple solution $C = kE$ and no apparent transfer of energy.

The other extreme case is any distribution of impressed force that can produce no current, although there is nowhere want of conductivity to prevent its doing so. For example, let the impressed force be distributed like the force due to a charge at a point, or a charge uniformly distributed over the surface of a sphere, that is, straight lines of force radiating from a centre. There can be no current, because there is no provision for supplying electricity *to* the centre, to satisfy the continuity of the current. Any number of such centres of force may coexist, producing a complex field of impressed force which cannot set up any current. The characteristic of such a field is that the work that would be done by the force on a charge if it were carried round any closed path would amount to nothing on completing a circuit; or, in other words, the work done from one point to another would be the same by any path; which implies that the impressed force is the space variation of a single valued function of position, say P; or $E = \nabla P$. But since there is no current there is no resultant force, hence the impressed force E or $\nabla P$ must be cancelled by an equally great, oppositely directed force of reaction, $= -\nabla P$. This is the supplementary force $e$, and it is derived from a potential, which is of course the electric potential. In the case of the closed tubes of force above, with current to match, there was no potential, nor any need of one. In the present case we have a potential, but no current.

The thermo-electric force arising from difference of temperature furnishes an example. In a single homogeneous conductor differences of temperature cannot keep up current. If $p$ be the thermo-electric power, the force $E = -t\nabla p$ per unit of length, $t$ being the absolute temperature. Here $\nabla p$ is obviously derived from a "potential," viz., $p$, but it is not that which makes its product into $t$ also be derived from a potential. The reason is that the thermo-electric power is a function of the temperature, and the direction in which the temperature falls fastest, also that in which the power varies fastest.

[We have $E = -t\nabla p$. Let E also $= -\nabla P$, where P is another scalar, so that $\nabla P = t\nabla p$. Now curl $\nabla P = 0$, so also curl $(t\nabla p) = 0$. But curl $\nabla p$ also $= 0$, and there is only left the condition that $\nabla t \parallel \nabla p$, or $p$ is a function of $t$.]

Between these two extremes of no potential and no current lie all other possible varieties that may arise. By the properties of the space variation of vectors, any distribution of E.M.F. may be considered as partly belonging to one extreme class and partly to the other. The given arbitrary distribution E considered to extend over all the boundless conductor (putting $E = 0$ where there is no impressed force) may be divided into two distinct distributions, say $E_1$ and $E_2$, of which the second is derived from a potential, say $E_2 = \nabla P$, and which by itself not being able to produce current may be left out altogether, whilst the first distribution $E_1$ consists wholly of closed tubes of force, and is therefore suitable for a current system. The current will be $kE_1$, and $E_1$ will be made up of the impressed force E and of the supplementary force $e$, which is the same as $E_2$ reversed, or $e = -\nabla P$.

As regards the energy, we required to have $\Sigma e\overline{C} = 0$. This is satisfied identically because C consists wholly of closed tubes, and $e$ is derived from a potential. The line integral of $e$ round any one of the tubes of C vanishes, consequently the whole sum vanishes.

The following is from a slightly different point of view; though virtually equivalent, it may be thought less abstract. Start with a single tube of impressed force, with coincident current, and no potential. Next, remove impressed force from a portion of the ring, leaving a discontinuity. The impressed force alone is now obviously insufficient to maintain any current. Supplement it by two fields, consisting of lines of force radiating equally in all directions from the ends of the tube, which fields by their co-existence form a single system of tubes starting from one end and ending at the other end of the tube of impressed force, and by union therewith completing the circuit. The system of force is now complete, and the potential and current are known.

What we have to do in the general case is therefore this. Go over the field of impressed force. Wherever we find it continuous, as much force leaving as entering a small space, leave it alone. But if we come to a small space where more impressed force enters than leaves, or where there is convergence, supplement it by an equal amount of divergence, by letting the proper amount of force leave the space, and spread in all directions equally. Do this wherever the impressed force has convergence, and we make the system of force complete.

The auxiliary field $e$ is thus made up entirely of central forces, varying as the inverse square of the distance, and is derived from a potential, or $e = -\nabla P$. The "matter," self-repulsive, which if it existed, would produce this force, would be distributed at the places of convergence of the impressed force; its volume density would be $\sigma$, if $\sigma$ stands for the convergence of $E/4\pi$. The potential is therefore $P = \Sigma\sigma/r$, as usual.

We have endeavoured in the above to show the nature and necessity of an *electric* potential in the case of a conduction current, quite apart from any consideration of electro-*static* potential, with which we have had nothing to do, having had no surface charges in question and no dielectric. Now, the potential function was originally invented to facilitate calculations relating to the attracting force of gravity, where real matter is concerned, situated at the centres of force, and its properties being equally applicable to electric and magnetic forces naturally led to support the idea that they were also due to attracting and repelling matter of some special kind situated at the centres of force. Now, we may idealise this entity, and let it be a mere symbol to represent the convergence of the force, which is almost what free electricity becomes in Maxwell's dielectric theory. But we have no justification to regard the $\sigma$ above as representing free electricity according to old ideas, or even what free electricity becomes in Maxwell's theory, because there really is no convergence of force. The divergence represented by $\sigma$, that is the divergence of the polar force, is merely introduced to cancel the convergence of the impressed force, which it does, producing continuity.

---

## METHOD OF CALCULATING THE STRENGTH OF THE MAGNETIC FIELD IN A SOLENOID.

BY W. BROOKS SAYERS.

The strength of the magnetic field inside a solenoid is nearly uniform in any plane parallel to the coils, except very near the wire (where the force is greater), and consequently calculations giving the force which would be exerted on a magnet pole in the axial line of the solenoid are sufficient for most purposes.

We may consider any solenoid to be made up of a number of equal rings, placed side by side (the dimensions of each ring may be chosen without reference to the size of the wire),

Digitized by Google

each ring standing for an equal number of similar turns, and making C in each ring equal to $nc$ (where $n$ is the number of turns in each ring, and $c$ the current in the wire), the calculated effect of the rings will not sensibly differ from the effect of the wires of the solenoid, provided we do not make each ring stand for too large a section of the solenoid, in other words, if we use a sufficient number of rings.

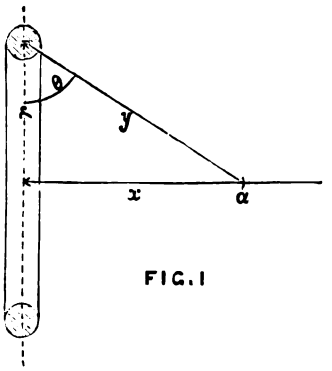

FIG. 1

The direction of the force exerted upon a magnet pole due to a current is in a plane at right angles to the direction in which the current is flowing, and in a circle having its centre in the conductor, it is proportional to the current and inversely proportional to the square of the radius of the circle.

From the definition of the unit magnetic field the force at the centre of a ring conductor in which a current is flowing is

$$f = \frac{2\pi r c}{10 r^2} \quad . \quad . \quad . \quad . \quad . \quad . \quad (1)$$

where $r$ is the radius of the coil measured in centimetres, C the current measured in amperes.

When the point ($a$, Fig 1) to be considered lies at a distance $x$ (Fig. 1) from the plane of the ring, but in a line perpendicular to the plane of the ring and passing through its centre, the formula becomes

$$f = \frac{2\pi r c}{10 y^2} \cos\theta \quad . \quad . \quad . \quad . \quad . \quad . \quad (2)$$

where $y$ is the distance in centimetres between the *wire* of the ring and the point $a$ (Fig. 1), and is equal to $\sqrt{x^2+r^2}$, $x$ being the distance, also measured in centimetres, of the point $a$ from the centre of the ring, and $\theta$ the angle made by the line $y$ with the plane of the ring.

In Fig. 2 let A A represent a ring (shown in section) around which a current is flowing. The force at 0 is readily obtained by formula (1), and similarly the forces at points 1, 2, 3, 4, 5, &c., centimetres distance from 0 along the line 0 ∞ could be obtained from formula (2). We will use only the first part

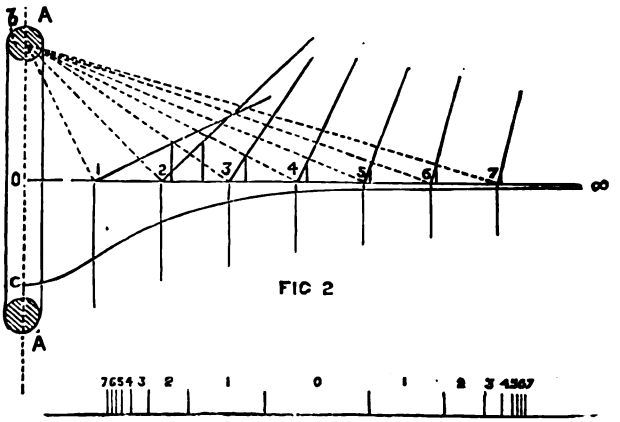

FIG 2

FIG. 3

of this formula, however, now, viz., $\frac{2\pi r c}{y^2}$, the factor cos $\theta$ can be more conveniently introduced by graphic means.

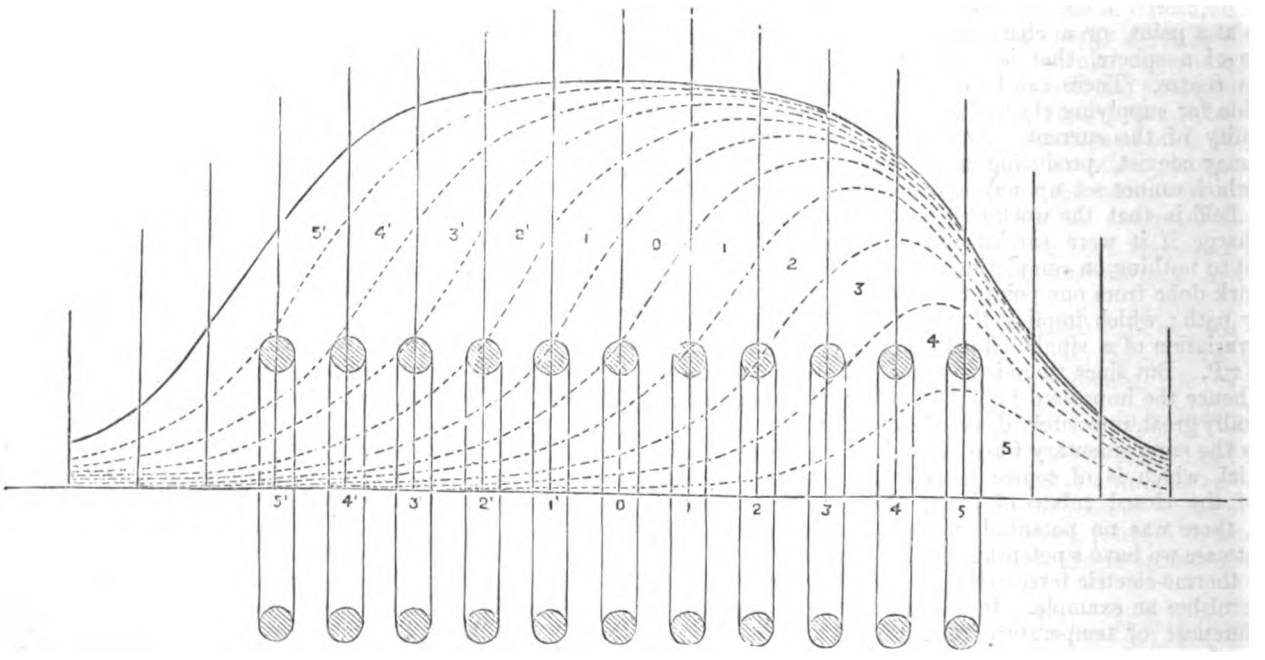

FIG. 4

Let the mean radius of the ring A A equal 2 centimetres, and let C, the current in the ring, equal 50 amperes, then the force at $0 = \frac{2\pi \times 2 \times 50}{10 \times (2)^2} = 15{\cdot}6$ units, and neglecting cos $\theta$ but obtaining $y^2$ (equals $(r^2+x^2)$) in each case, we get the quantities 12·56, 7·85, 4·81, 3·14, 2·16, 1·57, 1·19, when $x = 1$, 2, 3, 4, 5, 6, and 7 centimetres respectively. Let us now draw lines perpendicular to the line 0 ∞ (Fig. 2) at distances 1, 2, 3, 4, 5, 6, and 7 centimetres from the centre of the ring 0 (Fig. 2), and on the other side of the line 0 ∞ draw lines *perpendicular to lines joining the centre* (*b* Fig. 2) *of the wire of the ring* and the points 1, 2, 3, 4, 5, 6, and 7. The factor cos $\theta$ will then be introduced into the above quantities by marking them off on these lines (10 = 1 cent. in Fig. 2), and then taking their components along the line 0 ∞ by simply drawing lines perpendicular to 0 ∞ through the points so obtained. The curve $c$ ∞ (Fig. 2) is then readily obtained by making these components the ordinates (1 cent. = 10 units) at their respective points of action, and the ordinate of the curve at

Digitized by Google

any point in 0 $\infty$ represents the strength of field in magnetic units at that point.

Let us now suppose a number of rings similar to the one we have been considering, say 11, to be placed side by side with their axes coinciding and separated by equal distances—1 centimetre for convenience. The strength of field in the centre (0 Fig. 4) of the solenoid so composed will be the strength of field produced by a ring whose plane coincides with the point 0, plus twice the strength of field produced by a ring whose plane is at 1 centimetre distance, plus twice the strengths of field produced by rings at 2, 3, 4, and 5 centimetres distance.

The ordinates of curve (Fig. 2) supply the value of the field produced by a coil at these several distances, and by summing these ordinates on the edge of a slip of paper, putting the greatest in the centre, the next greatest on either side, and so on, with the decreasing values, as in Fig. 3, we obtain a scale by means of which we can readily plot a curve for *any number* of rings.

For example, in Fig. 4 is a curve for 11 rings. The value for the ordinate marked 0 is obtained from Fig. 3 by taking the 11 middle divisions, *i.e.* 5, 4, 3, 2, 1, 0, 1, 2, 3, 4, 5. The value for the ordinate coinciding with the plane of the end coil is obtained by taking 11 divisions from Fig. 3, starting from 0 and proceeding towards one end (if the divisions become too small to count before 11 is reached, as in our present example, we have simply to take all there are, knowing from this that the effect of the coils farthest off may be neglected), and so on, noticing that the greatest division on the scale (Fig. 3) is in the same relative position to the 11 divisions used as the ring with whose plane the point coincides is to the 11 rings composing the solenoid.

It will be noticed that the entire length of the scale (Fig. 3) represents *very nearly* the maximum strength of field obtainable by placing rings of the given dimensions at distances of 1 centimetre apart, and further, the curve (Fig. 4) shows why for a considerable portion of its length the strength of field in the solenoid is nearly constant.

The curve (Fig. 4) is divided into 11 sections of equal area; each section represents the effect of one ring, that is the ring numbered like it. This, of course, is not needed for practical purposes, but the points for all the curves are obtained by simply marking off the *intermediate* divisions of the scale (Fig. 3), *i.e.*, those lying between the points giving the ordinate required.

The accuracy of the method depends simply upon the number of imaginary rings into which the solenoid is divided. Where great accuracy is required, the value of the component ring of the solenoid may be obtained by again dividing this ring into smaller ones, both in a direction parallel to its plane and also into concentric rings, the sum of the effects of concentric rings being, of course, readily obtained by superposition.

Manufacturers would probably find it convenient to construct scales similar to Fig. 3 for rings of the sizes most frequently found in the solenoids they employ, by means of which they would be able to plot a curve for any solenoid that could be built up with them in a few minutes, as, if the units were chosen, as in the example given, the ordinates of the curve so obtained would only require multiplying by the ratio of the current to be employed in the solenoid to the current used in calculating the scales, viz., 50 amperes, in order to obtain the strength of field in magnetic units.

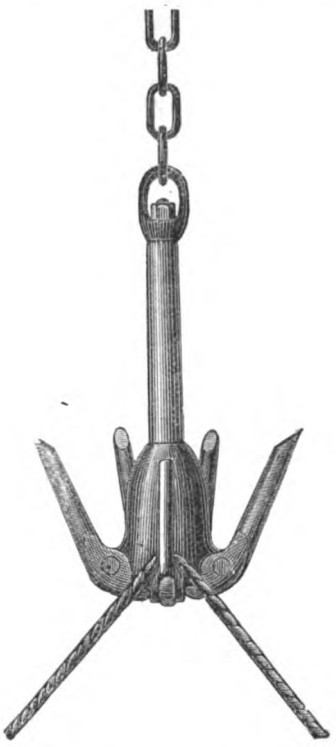
TELEGRAPHIC COMMUNICATION WITH LUNDY.—We understand that telegraphic communication with Lundy Island has been successfully completed. The work was carried out under the personal superintendence of Mr. Legge, telegraph engineer, of Nelson-street, Swansea.

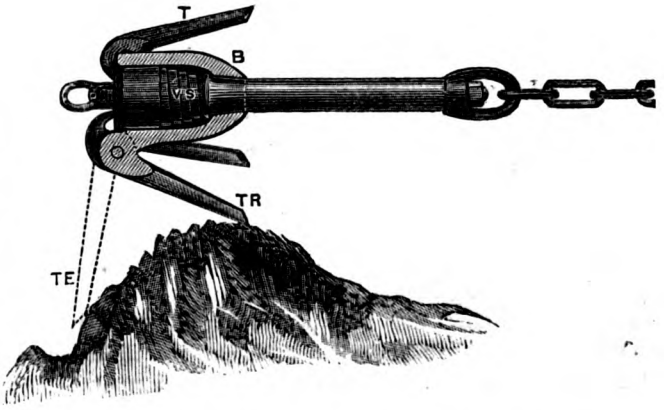
UNDERGROUND WIRES TO SCOTLAND.—Mr. Fawcett estimates that to put the line between London and Scotland underground would cost the country not less than a million and three-quarters sterling.

## JAMIESON'S GRAPNEL.

Some important improvements have recently been made in Jamieson's well known grapnel for raising submarine cables by Mr. Alexander Glegg, managing partner in the firm of Bowen and Co., Phœnix Foundry, Clerkenwell, who are the manufacturers. The grapnel is so constructed that when any of its five hinged toes engage with a rock they bend backwards and relieve themselves, immediately returning to their former position when the obstruction is passed; but the cable, if previously caught, is securely held in the bite of the short toes, which are rigid, and



form a part of the central boss, as shown in the engraving. In grappling with the older form, if the grapnel did not come across the cable at about right angles, the cable was apt to get jammed, and cut between the long movable toe and the short rigid toe. This is now rendered impossible by the long toe embracing the short one, in the same manner as the handle of a pocket knife embraces a short blade within it when shut. The cable, therefore, can be safely caught at any angle when it reeves down to the bottom crutch over the top of the short toe, which lies slightly below, and which only supports the cable when the long toe is drawn back by some obstruction. The shank, which was formerly screwed into the boss at B, occa-



T E, toe engaged with rock. T R, toe relieved. V S, volute spring. B, boss.

sionally got twisted out. It is now coned as shown, and pushed through from bottom end, being kept up to its place by the volute spring VS, which, at the same time acting on the piston, presses back the hinged toes after being engaged by a rock. The shank, although provided with a swivel shackle for chain, can itself swivel round in boss, whereas before it was fixed. The toes are now made of soft cast steel, which can be straightened if bent, or welded if broken, and the boss is made of cast steel or gun metal.

### IMPORTANT NOTICE.

*** All communications should be sent to our new offices, 1, Salisbury-court, Fleet-street, E.C., where *The Electrician* is now printed and published.

## THE FORTHCOMING MEETING OF THE BRITISH ASSOCIATION AT MONTREAL.

The hopes we expressed immediately after its last meeting that the British Association would lose no time in preparing for its Canadian campaign have, to all appearance, been realised. It would be premature to say that the arrangements are completed, or that nothing has been forgotten; but, judging by the programmes and voluminous notes sent to the various members and associates, the information already collected for the convenience of visitors shows that the officers of the Association have been hard at work, and are fully alive to the importance of being in good time. There are still four clear months between now and the assembly in Montreal, which is to hold its first public meeting on the evening of 27th August; but the particulars of routes, of charges, and of general travelling expenses already furnished by the Association are so full in almost every detail that no one need hesitate to make up his, or her, mind on the score of uncertainty as regards outlay and the means of doing the journey. This forwardness in the organisation is the more encouraging because the number of visitors will obviously be greatly increased by an early opportunity of studying ways and means, alternative routes, passage-moneys, and railway fares. On the other hand, the more people decide upon the trip the greater will be the facilities afforded them, and the less the general expenses.

It is gratifying to notice in this relation the friendly co-operation of the steamship companies on our side of the water, the passage-money by most of them having been greatly reduced in favour of members of the Association, whether going direct either to Montreal or Quebec, or to ports in the United States. Some of these companies proffer to run an extra steamer for the occasion early in August if a sufficient number of applications come in. Those who are unable to reduce their fares promise to give first-class accommodation for second-class fares, and second for third, which most people will consider a very satisfactory equivalent. In respect to all of them a liberal interpretation is put upon the term Member, which is to embrace three companions who are relatives and *bonâ fide* inmates of the member's household, provided they have paid their fee (£1) of associateship. This arrangement applies also, if we mistake not, to the privileges accorded on all the Canadian and States railways.

These last-named privileges are most munificent, and are an earnest of the spirit in which this visit is regarded by our hospitable friends on the other side of the Atlantic. A committee of reception has been formed in Montreal, and to its activity no doubt we owe much of the valuable information gathered together in the circular now before us relating to the routes, distances, fares, and so forth for every journey or tour that for business or pleasure is likely to be taken by any members of the Association. To begin with, the committee is authorised by the High Commissioner to announce that members of the British Association, with associates belonging to their family parties, will be conveyed free of charge over the Government railways on presentation of their vouchers. Thus, members landing at Halifax may travel free to Quebec, a distance of nearly 700 miles—the short remaining part of the journey over a line not owned by the Government, or by steamer, costing a mere trifle. The Canada Pacific Railway Company is not behind the Government in liberality; as, besides granting free passes over its lines to the North West, Rocky Mountains, Lake Superior and intermediate points, it offers to provide gratuitously certain special excursions to some famous but remote places of interest, the very mention of which is enough to make everybody wish to become a member of an association so favoured. One or two of the United States railways also, we are happy to notice, have been equally prompt and generous in their concessions, both by allowing a wide latitude in the selection of routes and in greatly reducing the fares, sometimes by one half, and in some instances by the issue of free passes over vast areas of country.

We have not nearly exhausted the catalogue of good things which are in store for visitors to this memorable gathering, and we have left ourselves hardly any room to comment on the business arrangements of the Association itself. That it will be a complete success there is little reason to doubt; besides the local interest manifested among the Canadians, our American cousins are bestirring themselves to share the general hospitalities, and much good may result from the intercourse of representative men of both nations who will come together for the first time face to face. If we have something to learn of Americans, we have much that we can teach them, and the auspices under which this year's meeting is conducted are sufficient guarantee for the honour of English science. We notice as a matter more particularly interesting to our readers that Section A comprises two interesting subjects for discussion, for which papers and speakers are invited, namely, one on The Seat of the Electromotive

Digitized by Google

Forces in the Voltaic Cell; the other on The Connection of Sun-spots with Terrestrial Phenomena. We look in vain, however, for any reference to special facilities for the Press. *The Electrician*, in any case, it is intended, will be represented there, and its readers may count on the fullest reports of the proceedings practicable; but their practicable extent must necessarily depend on what measures are taken by the Association in the interests of the scientific Press of this country.

## CLAUSIUS ON THE THEORY OF THE TRANSMISSION OF POWER BY DYNAMO-ELECTRIC MACHINES.

[We recently published a translation of an important paper by Professor Clausius on the "Theory of Dynamo-Electric Machines"—a translation which has since received special notice from Professor S. P. Thompson, no mean authority on the subject. We now take the earliest opportunity of presenting to our readers the substance of a second paper in prosecution of the same subject which has lately appeared in the *Annalen der Physik und Chemie*. This translation has been made for us, at Professor Clausius's own suggestion, by Mr. Walter R. Browne, M. Inst. C.E., already known as the translator of the same author's work on the "Mechanical Theory of Heat."]

1. *The Equations which hold for each Individual Machine.*

In the previous paper two equations were deduced which determine for any dynamo machine, when in motion, the work done by the mechanical force and the electromotive force. These equations are as follow :—

$$T = -\left[\frac{1}{a+i}\left(p+\frac{q}{b+i}\right)v+\left(\frac{l}{a+i}\right)^2\left(\sigma+\frac{\lambda}{b+i}\right)v^2\right]i^2 \quad . \text{(I)}.$$

$$E = \left[\frac{1}{a+i}\left(p+\frac{q}{b+i}\right)v-\rho v-\left(\sigma+\frac{\lambda}{b+i}\right)v^2\right]i \quad . \quad . \text{(II)}.$$

Here T is the work done during a unit of time by the mechanical force; E is the electromotive force; $i$ is the intensity of the current; $v$ the number of revolutions in the unit of time; and $a$, $b$, $p$, $q$, $l$, $\rho$, $\sigma$, and $\lambda$ are constants, of which those represented by Greek letters (especially the two latter) are small as compared with the others. If in these equations we bring the terms within the first curved bracket to a common diameter, and if we introduce a symbol $e$ with the signification

$$e = b+\frac{q}{b}, \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad (1)$$

then the two equations take the following and more simple form :—

$$T = -\left[\frac{e+i}{(a+i)(b+i)}pv+\left(\frac{l}{a+i}\right)^2\left(\sigma+\frac{\lambda}{b+2}\right)v^2\right]i^2. \quad \text{(Ia)}.$$

$$E = \left[\frac{e+i}{(a+i)(b+i)}pv-\rho v-\left(\sigma+\frac{\lambda}{b+i}\right)v^2\right]i \quad . \quad \text{(IIa)}.$$

These equations can also be used in considering the transmission of power, especially in the case in which two dynamo machines are connected together by a wire, and one of these is driven by a motor of any kind, whilst the other is set in motion by the electrical current within the wire, and can thus perform mechanical work. To make the application to this case as convenient as possible a slight simplification is still necessary. The second machine, which is moved by the electric current, turns in the opposite direction to that which generates the current; and therefore, if this fact is to be expressed in the equations, the magnitude $v$ must have a negative sign for the second machine. Moreover, since the motion of the second machine is in opposition to mechanical force, whilst the first machine is set in motion by mechanical force, we must, in order to express this, give the work T a negative value in the first machine, and a positive value in the second machine.

Finally, the induced electromotive forces in the two machines have also opposite directions, and therefore, for their complete determination, must be also expressed by positive and negative signs.

In practice, however, it would be inconvenient to be always speaking of negative velocities in the case of one machine; and hence it is usual to represent the velocities of rotation in the two machines by the numbers of revolutions, which are absolute magnitudes, and thereby to pass over as obvious the circumstance that the rotation in the two machines has opposite directions. It is also assumed as evident that in the one machine power is consumed, and in the other power is given out, and that the induced electromotive forces in them have opposite directions. Thus, in determining the work done, and the electromotive forces, it is considered sufficient to give their absolute values. In accordance with this we shall use $v_1$ and $v_2$ to signify the two figures for the number of revolutions in the two machines, without reference to the direction of rotation. $T_1$ and $T_2$ will signify the absolute values of the two quantities of work, and $E_1$ and $E_2$ the absolute values of the two electromotive forces.

With these assumptions the equations for the first machine or generator are as follow :—

$$T_1 = \left[\frac{e+i}{(a+i)(b+i)}pv_1+\left(\frac{l}{a+i}\right)^2\left(\sigma+\frac{\lambda}{b+i}\right)v_1^2\right]i^2 \quad . \text{(III)}.$$

$$E_1 = \left[\frac{e+i}{(a+i)(b+i)}pv_1-\rho v_1-\left(\sigma+\frac{\lambda}{b+i}\right)v_1^2\right]i \quad . \quad . \text{(IV)}.$$

In order to form the corresponding equations for the second machine, or the receiver, a remark is still necessary as to the signs to be given to those terms which have $i^2$ as a factor, and as to the term $\rho v$. If for the moment we leave the latter term out of account, the following holds for the other terms. If T and E are determined with their proper signs, we must, in order to transform the equations of the first machine to suit the second machine, replace $v_1$ by $-v_2$. By this means the terms of the first degree would change their sign, but those of the second degree would keep it unaltered. If, on the other hand, T and E are only to be determined by their absolute values, then in the cases where the method just described would give negative values for T and E, we must change all the signs on the right-hand side. The result of this is that in the equations for the second machine the terms of the first degree have the same sign as in the equations for the first machine, but the terms of the second degree have the opposite sign. Again, if we turn to the term $\rho v$, hitherto neglected, the electromotive force which is represented by the product $\rho v i$ always acts in the opposite direction to that of the current $i$. Hence, in the first machine, in which the whole of the induced electromotive force has the direction of the main current $i$, the E.M.F., represented by $\rho v i$, will go to diminish the net absolute value of the E.M.F. This corresponds to giving $\rho v$, in equation IV., the negative sign. On the other hand, with the second machine, in which the whole of the electromotive force acts in the opposite direction to the current $i$, the electromotive force represented by the above product will go to increase its absolute value, for which reason the term $\rho v$ must have the positive sign. Hence for the second machine the equations take the following form :—

$$T_2 = \left[\frac{e+i}{(a+i)(b+i)}pv_2-\left(\frac{l}{a+i}\right)^2\left(\sigma+\frac{\lambda}{b+i}\right)v_2^2\right]i^2 \quad . \text{(V)}.$$

$$E_2 = \left[\frac{e+i}{(a+i)(b+i)}pv_2+\rho v_2+\left(\sigma+\frac{\lambda}{b+i}\right)v_2^2\right]i \quad . \text{(VI)}.$$

In the forming of these equations it is assumed that the second machine is in all respects like the first; if it is different the constants in the equation, which depend upon the nature of the machine, will have different values in the two cases, and this difference must be expressed by some means or other, as by giving different indices to the letters which symbolise them.

The four equations III., IV., V., VI., can now be used to facilitate various calculations as to the common action of the two machines.

## CORRESPONDENCE.

### THE CAUSES OF HEATING IN THE IRON CORES OF ARMATURES.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: At a recent meeting of the Society of Telegraph Engineers the question was raised in the discussion which followed Mr. Mordey's interesting paper on "Certain Prejudicial Action in Dynamo Machines," whether the cause of heating in the iron cores of armatures was due to molecular movement or eddy currents? No demonstration was given to prove the former conclusion, and in his reply Mr. Mordey preferred to attribute this heat development to the latter cause, stating as his reason for this opinion that there was no proof to show that molecular movement produced heat. With all due deference to Mr. Mordey's experience, may I ask his and your readers' consideration of the following note, which is intended to show that certainly *part* of such heating is attributable to molecular movement:—

It has been proved beyond doubt by Dr. Joule that when a piece of iron is magnetised its length becomes increased (this lengthening is not confined to iron, in which the increase is about $\frac{1}{720000}$th) along the axis of magnetisation. This increase of length must take place in the iron ring or drum of an armature, thereby causing a deformation of its shape; but the armature is rotating, consequently every part of it is continually changing position relatively to the direction of the axis of magnetisation. It is inconceivable that such a strain, involving undoubted molecular change or movement, should be unaccompanied by molecular friction. For example, when testing any material, such as iron or steel, for tensile strength, the elongation and diminution of area consequent on the application of stress is always accompanied by a very sensible manifestation of heat. In the armature, as shown above, the strain is continually changing its direction, consequently there is a constant expenditure of energy required to produce the stress corresponding to the strain.

This may not seem a very complete demonstration of the problem, but it may serve the purpose of opening a discussion on a point which, though of minor detail, has an important bearing on the efficiency of dynamo machinery.—Yours, &c.,

Isleworth, March 24th, 1884. F. H. NALDER.

P.S.—The testing of iron before and after magnetisation might afford an investigation by no means devoid of interest.

### OVERHEAD AND UNDERGROUND TELEPHONE WIRES.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: I have waited a week before replying to your correspondent, "Telephonist," because the United, or other interested company, seeing his letter, might wish to repudiate his advocacy in their favour, unless he is writing with their approval, if not at their instigation. I will assume, therefore, that "Telephonist" speaks with full knowledge, if not authority, on the subject. He begins by saying that the policy of the telephone companies cannot be understood without a tedious discussion of technical details. Well, *The Electrician* is a journal devoted to the discussion of technical details, and I feel sure, from the remarks of "Telephonist," that the discussion is not likely to be tedious. He professes to speak from a thorough practical knowledge, and, if he is not afraid of his opinions being examined, he can evidently do much to make this subject interesting, and I sincerely trust he will not be offended or discouraged if his present contribution gets freely handled. He evidently believes in the United Telephone Company, whilst the public is losing faith fast. On the same page as the letter from "Telephonist" is a letter from Mr. J. T. Hutchinson, showing how the United Telephone Company might abuse the confidence which their Bill asks for. Judging the future from the past, that letter is no exaggeration of the advantage they would take of such power where prompted by passion or prejudice, as circumstances might arise. It may seem unreasonable to suppose that passion or prejudice would be allowed to influence a respectable body of gentlemen occupying such a position of trust and honour, but I may have to show that in some cases where they have "put down their foot" it is easy to trace the cloven hoof.

"Telephonist" admits that it is improper to fix overhead wires in long spans diagonally across the streets, and states that the U.T. Co., if they got their Bill passed, would cross the streets at right angles, and run the wires over the housetops, and parallel with the streets. This might be all "plain sailing." At any rate, it would be an interesting sort of "rig," forming a novel "tie," whereby artistically to "pull together" the composition of street architecture, especially as a relief to the "sky line." But if the company seriously entertain such a change of programme, the wording of their Bill would be very different from what it is in many places. Besides, there is not a word from beginning to end that suggests in the slightest degree any such intention. If "Telephonist," therefore, has the least foundation for his statement, he ought to explain the contradiction.

When he says the company requires the Act of Parliament to enable them to meet the constant demands, he again seems to be ignorant of facts, for on comparing the total number of subscribers in the lists published periodically by the company, there seems to be a balance between those taking to the use of the telephone and those giving it up. What has "Telephonist" to say to that?

But the next four lines of his letter seem to be so fully inspired that I must quote them.

"If the company get the power to suspend the wires over housetops without paying anything beyond damages to roofs, they do not expect there will be any necessity to lay wires underground. Is this not clear and reasonable?"

This is really a beautiful specimen of artlessness, for whilst it seems to express the whole scope and objects of the Bill, it would be a scandal and a disgrace to the company if it were proved to be true. In the Bill it is seriously contemplated, and arrangements are specified by which it is proposed to lay wires underground. So that if the proposal is only made to hoodwink Parliament and the public whilst they get full powers over all housetops, it is a trick more contemptible than cunning. And yet I venture to say that if any impartial person will read the Private Bill addressed to Parliament and the speeches of the chairman and vice-chairman addressed to the company's shareholders, they will find the quotation from "Telephonist" the only intelligible explanation of the contradiction, and he follows it up by the usual telephonic claptrap about "induction" to prove that telephone wires underground would be practically useless.

I must pause here for two reasons. "Telephonist" seems to want to leave off just where I should like to begin, and if I were to conclude my answer to him in this letter I am afraid it would be too long for insertion. In my next I will deal with that "induction" question, but I should also like to ask "Telephonist" whether he will not give some reasons of his own why everything that is evil in the working of the telephone system is always put down as "induction." Is it to put off till a more convenient season a number of inconvenient questions? And is that question of "induction" one of those things which, it is assumed, "no fellah can understand?" I will then reply also about the difference between public policy and the United Telephone Company's policy.—Yours, &c.,

MOS LEGEM REGIT.

### THE INTERNAL RESISTANCE OF A BATTERY.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: I observe in your issue of January 5th, under the heading of Students' Columns, a proof by Mr. Rimington of Mance's method of finding the internal resistance of a battery. I am surprised that this proof has remained so long without comment, calculated as it must be to perplex and mislead a thoughtful student. In the interest of those (I hope) numerous students who seek information in your journal, I venture to submit the following criticisms on Mr. Rimington's proof, and

Digitized by Google

also an alternative investigation of the same formula, which my own pupils have found no difficulty in understanding.

Referring to Mr. Rimington's diagram (Fig. 1), and using the same notation, from the fourth equation

$$\frac{a}{b}=\frac{d-f}{c-f} \quad \ldots\ldots \quad (4)$$

is deduced

$$\frac{\frac{O-P}{A}}{\frac{Q-O}{B}}=\frac{\frac{P-R}{D}+f}{\frac{R-Q}{C}+f} \quad \ldots\ldots \quad (5)$$

This I take to be a mere misprint for

$$\frac{\frac{O-P}{A}}{\frac{Q-O}{B}}=\frac{\frac{P-R}{D}-f}{\frac{R-Q}{C}-f}$$

$\frac{P-R}{D}$ is substituted for $d$, but the potential R is higher than the potential P, $\therefore \frac{P-R}{D}$ is negative, whereas $d$ certainly flows from P towards R.

The truth is that $d$ is not equal to $\frac{P-R}{D}$, but to $\frac{V+P-R}{D}$, where V is the E.M.F. of the battery.

Again, it is stated that "For $e$ to remain the same, whether the conductor F be closed or open, in which latter case $f=0$, $f$ must be 0 in the former," and "when $f=0$, $P=Q$." Now,

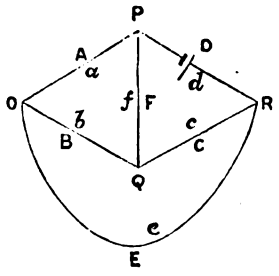

Fig. 1.

according to the figure given, a current flows from Q to O, $\therefore$ the potential O is lower than the potential Q. Also a current flows from O to P, $\therefore$ P is lower than O, and, *a fortiori*, P is lower than Q.

I have no means of experimenting at hand, but if any of your readers will insert a galvanometer in O Q of resistance B, such that $\frac{B}{A}=\frac{C}{D}$, taking care that P and Q are connected by a conductor having practically no resistance, I can confidently predict that a current will be found to flow from O to Q and not from Q to O.

Here, then, we have this difficulty. If the potential Q is to be equal to P, we must have currents flowing in directions O Q and R Q, in which case $f$ cannot be 0. The real explanation is that when the resistance F is very small, the difference between P and Q is also very small, and were F to be actually zero, P – Q would also be zero, in which case $f$ would assume the indeterminate form $\frac{0}{0}$.

Making the above corrections, Mr. Rimington's sixth equation becomes

$$\frac{B\,(O-P)}{A\,(O-Q)}=\frac{C\,(V+P-R-f\,D)}{D\,(R-Q-f\,C)},$$

and it is seen that when $P=Q$ and $\frac{B}{A}=\frac{C}{D}$, $f$ is not zero, but $\frac{V-2\,(R-Q)}{D-C}$.

Closing the circuit P Q alters the total external resistance of the circuit, and therefore the total current leaving the battery, but it also alters the ratio borne to this total current by the part of it, $e$, which flows through the galvanometer. Thus it is quite possible that although in one case there is no current between P and Q, and in the other there is a definite current, yet the deflection of the galvanometer should remain the same.

The following is a direct deduction from Ohm's law, and furnishes, I think, a good example of the calculation of the joint resistance of a complicated circuit :—

When the connection between P and Q is broken, the circuit may be represented by Fig. 2. The total current leaving the battery is

$$\frac{V}{D+A+\frac{(B+C)\,E}{B+C+E}}=C_1,$$

$\therefore$ the current through the galvanometer,

$$\frac{B+C}{B+C+E}C_1=\frac{(B+C)\,V}{(B+C+E)\,(D+A)+(B+C)\,E}=I_1.$$

When P and Q are connected by a conductor having no resistance they become virtually coincident points, and the circuit may be represented by Fig. 3.

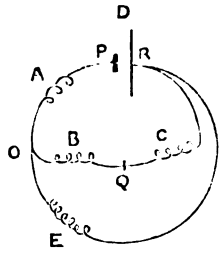

Fig. 2.

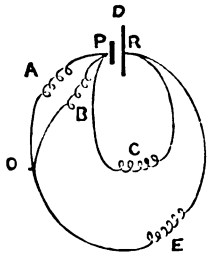

Fig. 3.

The total current leaving the battery,

$$\frac{V}{D+\frac{\left(E+\frac{A\,B}{A+B}\right)C}{E+\frac{A\,B}{A+B}}}=C_2$$

and the current through the galvanometer

$$E+\frac{\frac{C}{A\,B}}{A+B}+C \times C_2=\frac{C\,V}{D\left(E+\frac{A\,B}{A+B}+C\right)+C\left(E+\frac{A\,B}{A+B}\right)}=I_2.$$

Now, when the deflection in the two cases is the same, we know that

$$I_1=I_2,$$

whence

$$\frac{B+C}{D\,(B+C+E)+(A+E)\,(B+C)+A\,E}=\frac{C\,(A+B)}{D\{(A+B)(E+C)+A\,B\}+C\,(E\,A+E\,B+A\,B)}$$

$$D\{(A+B)\,(E+C)\,(B+C)+A\,B\,(B+C)-C\,(A+B)(B+C+E)\}=C\,(A+B)\,(B+C)\,(E+A)+A\,E\,C\,(A+B)-C\,(B+C)\,(E\,A+E\,B+A\,B).$$

$$D\{(A+B)\,(B+C)\,E+A\,B\,(B+C)-E\,C\,(A+B)\}=C\{(B+C)\,(A\,E+A^2+B\,E+A\,B-E\,A-B\,E-A\,B)+A\,E\,(A+B)\}$$

$$D\,B\,(B\,E+A\,E+A\,B+A\,C)=C\,A\,(A\,B+A\,C+E\,A+E\,B).$$

$\therefore$ since the common factor cannot vanish

$$D\,B=C\,A.$$

*Q. E. D.*

I have also applied Kirchoff's laws to this question, obtaining virtually the same equation; this I find is the method adopted by Professor Clerk Maxwell, *vide* Maxwell's "Electricity and Magnetism," Vol. I., Art. 357.

Mr. Oliver Lodge has pointed out that the accuracy of this

Digitized by Google

test rests upon the assumption that the E.M.F. of the battery is the same, whatever current is passing through it, whereas such is not the case, vide *Philosophical Magazine* for 1857, Vol. I., pp. 515—525.—Yours, &c., C. E. HILLYER.

Lausanne, Switzerland.

## THE ELECTRIC LIGHT FOR RAILWAY CARRIAGES.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: I thank you for noticing my short paper, and if, after I have had an opportunity of replying to the discussion, you should return to this subject, I hope to show that you may have got hold of the wrong end of the stick.

You are hard upon us all, but especially so upon those who, being every whit as candid as I tried to be, do not attach much importance to what, from my point of view, appears to be the chief question, viz., the cost of producing the light. When once this can be satisfactorily settled, it may or may not be possible to meet all the sentimental objections which have been raised to the purely mechanical means I recommend, but I believe that most of the practical difficulties will be very easily overcome.

I am not, as you rightly suppose, interested in any particular system, but I trust that Mr. J. Staats Forbes (to whom all the credit is due for the recent experiment on the District Railway) will not allow the matter to drop; for if, as I understand, he has placed it in the hands of the Edison and Swan United Company, it ought to be made a great success.—Yours, &c., WM. H. MASSEY.

6, Westminster-chambers, London, S.W.,
March 25, 1884.

## THE GAULARD-GIBBS SYSTEM OF DISTRIBUTING ELECTRICITY.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: In your impressions of the 23rd February and 2nd March (instant) you referred to the Gaulard-Gibbs system of electrical distribution employed in lighting five stations of the Metropolitan Railway. I have now the pleasure to send you the official report of Dr. Hopkinson, which gives the practical results obtained from the secondary generator.—Yours, &c.,

J. E. PICKERING, Secretary.

The National Company for the Distribution of Electricity by Secondary Generators (Limited), 18, Warwick-street, Regent-street, W., 24th March, 1884.

4, Westminster-chambers, Victoria-street, S.W.,
March 14, 1884.

To the National Company for the Distribution of Electricity by Secondary Generators (Limited), 18, Warwick-street, Regent-street, W.

Gentlemen: Having tested the instruments which I used in the experiments made at Edgware-road on the 11th and 12th inst., I am in a position to give you the precise results which they indicate. The measurements were made with a Thomson quadrant electrometer by the methods first used some years ago by M. Joubert in Paris. The constant of the instrument was determined in my laboratory and was based upon Clark's standard cell. This method is free from the undoubted theoretical objections to the use of the electro-dynamometer for determining alternating differences of potential or work done by alternating currents. On the 11th instant the whole electrical power developed by the Siemens alternating current machine was determined by six readings of the electrometer, agreeing with each other, to be 16,710 watts. The secondary generator, in constant use for lighting the Edgware-road Station, was also tested. This secondary generator consists of sixteen columns, twelve of which were in actual use, no current being taken from the other four; eight were devoted to lighting twenty-seven incandescent lamps, and four to two Jablochkoff candles. During a portion of the time the Jablochkoff candles were extinguished in order to enable me to determine the efficiency of the part devoted to the incandescent lights.

It was noted that when one part alone of the apparatus was in action considerable electrical disturbance took place in the unemployed columns, which would be prejudicial to the economical return of the secondary generator. This being a mere matter of adjustment which may be effected in a few moments is of little consequence. The results, however, were as follow:—

| | | |
|---|---|---|
| Jablochkoff candles lighted— | | |
| Work applied to primary between terminals | 2,767 | watts |
| Work delivered from terminals to incandescent lamp circuit | 1,459 | ,, |
| Jablochkoff candles cut out— | | |
| Work applied to primary between terminals | 2,131 | ,, |
| Work delivered from terminals to incandescent lamp circuit | 1,689 | ,, |

Showing an efficiency of 79·3 per cent.

If we compare the electrical work actually developed by the Siemens machine and the number of lights lighted on the system and the resistance of the main line it would appear that the average efficiency of the other secondary generators must be better than that at Edgware-road, which is explained by my preceding remark, all the columns of the secondary generators supplying the stations at Aldgate and King's Cross being in use. In effect, the total electrical work being, as I have stated above, 16,710 watts may be accounted for thus:—

| | | |
|---|---|---|
| 151 incandescent lamps × 63 watts | = 9,513 | watts |
| 5 Jablochkoff candles × 375 ,, | = 1,875 | ,, |
| Resistance of main line 30 ohms, Primary current 11 amperes | = 3,630 | ,, |
| | 15,018 | ,, |

Giving an efficiency of secondary generator 89 per cent.

On the 12th instant a small secondary generator, a recent invention of Messrs. Gaulard and Gibbs, was tested. The simplicity of construction of this apparatus is remarkable. The second circuit was closed upon a resistance of German silver wire, reported to me to be 1·8 ohm, but which I find to be 1·9 ohm. The results obtained were:—

| | | |
|---|---|---|
| Work applied to primary between terminals | 230 | watts |
| Works delivered from terminals to German silver resistance | 198 | ,, |

Giving an efficiency of 86·1 per cent.

As a check upon my results, a Siemens electro-dynamometer was introduced into the secondary circuit, and the current through the same resistance was measured 10·3 amperes, equivalent to 201·4 watts, a result agreeing well with the electrometer measurements, considering the great difference between the two principles of the two methods of measurement. The amount of work absorbed and delivered by this generator was small, but I have very little doubt that this is simply due to the resistance interposed in the secondary circuit being much too small, and I would recommend that some experiments be tried with other resistances. The measurements could easily be made with the Siemens electro-dynamometer any evening if you will have the following resistances prepared—30, 20, 10 and 5 ohms.—I am, Gentlemen, yours truly, (Signed) J. Hopkinson.

## HYDROGEN AMALGAM.

Hydrogen amalgam is the name given to a compound of the fluid metal mercury with the gaseous metal hydrogen, which is used in a new process for the "quickening" of mercury employed for amalgamating the precious metals contained in ores and other compounds. It is known that if gold and silver and certain other metals be brought into contact with clean or "quick" mercury, that this latter dissolves out the former from the ore. When, for instance, gold is thus dissolved by mercury, the compound of gold and mercury thus formed is termed a "gold amalgam." By means of this property of dissolving certain other metals which is inherent in mercury, a very large proportion of the gold and silver in use has been obtained. The value not alone of the gold thus dissolved out, but also of the large quantities of mercury required for the purpose render any improvement in

Digitized by Google

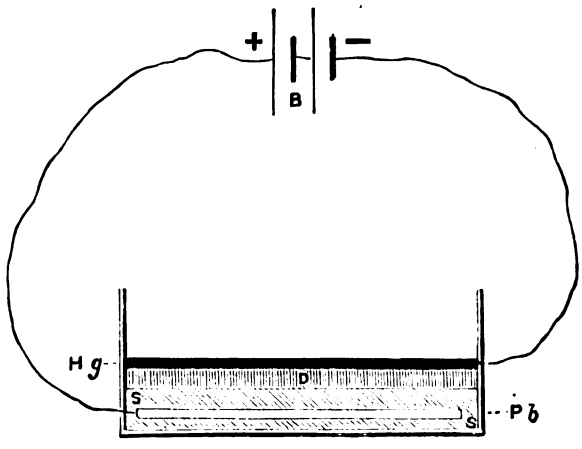
using the fluid metal not only interesting but also commercially very important. When it is remembered that mercury cannot in practice be made to absorb at one time more than a small percentage of its own weight of the precious metal, and that in very many cases considerable loss of mercury results from causes mentioned below, it will be realised how imperative is the demand for a more perfect and economical method of using the fluid metal.

We may shortly explain for the benefit of our readers not experienced in the use of mercury for the extraction of the precious metals from ores the outline of the operation in general use. Given an ore which, say, contains one ounce of gold to the ton, the ore in the first place is crushed into a fine powder by means of an ordinary stamping or crushing mill. The very fine particles of gold disseminated through the ore are thus to some degree laid bare, the degree or quantity of exposed surface being more or less in proportion to the fineness of the crushing. Having by this means exposed the particles of gold, the next step is to bring these particles into contact with the mercury. There are numerous devices for effecting this, and we will take for the purpose of explanation one in ordinary use, viz., the "table." This consists of an inclined plane made of wood, or other suitable material, about 4ft. wide, and of varying lengths. At short distances from each other are transverse shallow grooves filled with mercury, thus forming a succession of ditches containing the fluid metal. The finely-crushed ore is now carried down this inclined plane by means of a stream of water, and as the ore and water cross each of these ditches, or "riffles," as they are technically called, the particles of gold are to some extent at least brought into contact with the mercury contained in each riffle, thus enabling the fluid metal to dissolve out the gold. When the mercury has dissolved out sufficient gold, the gold amalgam thus obtained is placed in a sealed iron retort, and subjected to heat. The mercury is vaporised by the heat, carried through a condensing tube, and collected in water. The gold left in the retort when the operation is completed is collected and fused in the usual manner. So far we have outlined the ordinary process without adverting to any of the difficulties met with in gold and silver amalgamation.

There are two well-known difficulties, viz., the one where the dissolving power of the mercury is impaired by the metal becoming "sickened," and the other the case of "float gold," that is gold in such fine particles that it floats upon the surface of the stream, and so does not come into contact with the mercury. We have mentioned that mercury, when in proper condition, has the power of dissolving gold and silver, thus acting as the agent for the extraction of the precious metals from their ores. When, however, the surface of the mercury becomes oxidised, or otherwise chemically affected by air and certain ingredients in the ore to be heated, as happens more or less in all cases, then the power of the mercury to dissolve the precious metals is impaired, for the following reason :—A sulphide or oxide of the mercury, for instance, will form a thin non-fluid scum upon the surface, and prevents contact between the particles of gold and the clean mercury. When mercury is thus injuriously acted upon by deleterious components in the ore it is said to be "sick." When the mercury is so sickened, then the friction of the ore passing over it breaks up the scum into small particles, an effect which is technically called "flouring." This floured mercury is easily carried away with the residual ore or "slimes," thus leaving fresh surfaces of the fluid metal to be sickened. More than this, the mercury under such conditions becomes less mobile and fluid, and particles of the unaltered metal are easily carried away with the sickened portion of the mercury. In some cases this sickening action is so rapid that the whole of the mercury is carried away in the slimes and is lost. A large proportion of the auriferous and argentiferous ores contain in varying quantities these deleterious ingredients. Such ores are termed "intractible," *i.e.*, difficult or impossible to treat by amalgamation. This "sickening" and consequent "flouring" is, it will be readily understood, a great difficulty in gold and silver amalgamation. The second difficulty above alluded to is that of "float gold." Our readers will probably have observed in workshops where very fine particles of iron are to be found that, notwithstanding the greater specific gravity of the metal, the fine particles will float upon the surface of the fluid, even when the water is agitated. In the same manner fine particles of gold will float upon the surface of the stream of water running over the "tables." Where the gold thus floats upon the surface of the stream it does not come into contact with the mercury, and consequently passes away and is lost in the slimes. In many ores there is found considerable quantities of this "float gold," and in some cases all the gold present is of this character. To sum up, therefore, we may say that a perfect process should overcome both these difficulties.

We have lately seen a process designed to overcome both of the difficulties in question. It is the invention of Mr. Bernard C. Molloy, M.P., a barrister, of the Middle Temple.* Mr. Molloy's invention involves the electrolysis of acid, alkaline, or saline solutions, and the use of a porous diaphragm in the process, as will be seen below. The process is applicable to all existing classes of amalgamating machinery, but for the purpose of explanation we will refer to its application in the case of the "riffle" in an amalgamating table, as above described. Mr. Molloy constructs the bed of the "riffle" of a porous material, such as cement, non-resinous wood, untanned leather, or like material. Lying underneath this bed, or porous diaphragm, is supported a thin layer of sand, or other suitable material, saturated with a dilute acid or an alkaline or saline solution, such as ($H_2SO_4 = xH_2O$) dilute sulphuric acid; ($KHO = xH_2O$) caustic potash, or ($Na_2SO_4 = xH_2O$) sulphate of soda. A small platinum wire dips into the mercury, and is connected by a copper wire with the zinc element or negative pole of a source of electricity. In the bed of sand saturated with the solution as above mentioned is a plate of lead or other suitable material, and this latter is connected with the carbon element or positive pole of the same source of electricity.

The following diagram will render the arrangement clear.



$Pb$ is the lead anode, which is preferably constructed of the metal in the porous condition. SS is the layer of sand in which the anode is embedded, D is the porous diaphragm, $Hg$ the amalgamating mercury constituting the cathode, and B is the battery or other source of electricity.

For a bed of mercury of about 100lb. Mr. Molloy uses only two, or at most four, chromate of lime cells. He finds that two cells having an electromotive force of about two volts each suffice for his purpose. The requisite electrical power can, of course, be obtained from a very small dynamo machine. In connection with the electromotive force which is necessary, it may be observed that an amalgam of sodium containing only a small quantity of this metal would, when constituting a positive element in connection with a lead negative and an aqueous electrolyte, give an opposing electromotive force of less than three volts. The electrical resistance of the apparatus is so small that no electrical power is wasted. The electrolyte is so

* Mr. Molloy is one of the inventors of the chromate of lime battery, the apparatus for which is more commonly used as a bichromate or nitric acid cell. He is also one of the inventors of the process for the regeneration of nitric acid, which was recently mentioned in our columns (p. 349).

Digitized by Google

small in quantity, so cheap, and so easily to be obtained that its cost is negligible, as it is scarcely subject to waste.

The apparatus being so arranged, when the circuit is closed the mercury is rapidly agitated by the evolution of hydrogen from its surface. Mr. Molloy maintains, and we think rightly, that there is a definite chemical compound of the gaseous metal hydrogen and the fluid metal mercury, and that the hydrogen evolved is only the excess over that retained by the fluid metal. In the case of an electrolyte composed of dilute sulphuric acid the compound obtained is a simple "Hydrogen Amalgam," but where the electrolyte is one containing sodium or potassium, then the compound is, as the case may be, a "Potassium-Hydrogen Amalgam" or a "Sodium-Hydrogen Amalgam." In these latter cases some quantity of these metals is dissolved out, enters into combination with the mercury, and in the presence of water is converted by this latter into the hydrate of the alkaline metal, and also gives hydrogen to the mercury.

The presence of this hydrogen in the mercury thus obtained prevents the possibility of the sickening of the fluid metal, and renders it highly mobile and fluid. When it is in this state the ore passes over it without in any way disturbing the fluid metal, and the mercury, thus "quickened," rapidly and with certainty dissolves any gold that is brought into contact with it; and in this manner not only is the mercury saved from loss by "flouring," but the precious metals are most effectively dissolved by amalgamation. The cost of the electricity is so small that a quarter of a horse-power would be sufficient for works treating large quantities of ore, and the method of application to apparatus in present use in no way affects the mechanical working of the latter.

The second portion of the process, viz., that which ensures absolute contact between every portion of the gold and the mercury "quickened" in the manner just described, we must reserve for a future article. The method employed is based upon a very simple principle, in the adaptation of which Mr. Molloy secures a contact between the gold and the mercury, prolonged at will from 30 to 60 seconds.

It is not our province to give a verdict as to the mechanical suitability of apparatus employed in metallurgical or mining operations, but we may say that, from an electrical point of view at least, the apparatus devised by Mr. Molloy is superior to anything of the kind that has yet been brought to our notice.

---

## RECENT PROGRESS IN DYNAMO-ELECTRIC MACHINES.*

By Professor SILVANUS P. THOMPSON, B.A., D.Sc., M.S.T.E.
University College, Bristol.

(CONTINUED FROM PAGE 450.)

My second method of using these armatures consists in jerking the coils through a distance equal to their own thickness, the coils being successively placed at different positions in the field, the throw of the galvanometer being observed as before. Each of the coils occupies as nearly as possible 15° of angular breadth. Accordingly, I have two stops set, limiting the motion of the handle to that amount, and at the back there is a graduated circle enabling me to set the armature with the coils in any desired position. If we move the coils by six such jerks, through their own angular breadth each time, then starting at 0° the sixth jerk will bring us to 90°. I have plotted out in Fig. 16 the three curves thus obtained, and the corresponding numbers are given in Table A.

These figures leave no doubt as to the question at issue. The Gramme pattern of ring armature, so far from being an improvement on the Pacinotti, is distinctly a retrograde step; always supposing that the cost of construction, liability to heating, and other kindred matters be equal for the two. The significance of this point will be resumed at a later period in this paper.

Before leaving the theory of armatures, to pass to that of field-magnets, I should wish to say that the experiments which I have made, and also those of Dr. Isenbeck, have been so instructive to myself, that I have already begun a similar series of observations on other forms of armature. I hope in due time to make known the results of my investigations.

But little advance has been made in theory so far as relates to the field-magnets. The law of saturation of an electro-magnet remains still an empirical law. It is satisfactory, however, that such widely differing authorities as Professor Clausius, M. Marcel Deprez, and Professors Ayrton and Perry agree in accepting the empirical formula of Fröhlich as a sufficiently accurate expression for the law of saturation.

TABLE A.

| | GRAMME. | GRAMME. | PACINOTTI. |

| 75°—90° | 30 | 220 | 360 |

Some progress has been made in the theory of the lead that must be given to the brushes of the dynamo. Formerly this was ascribed to a sluggishness in the demagnetisation of the iron of the armature; but in 1878, the late M. Antoine

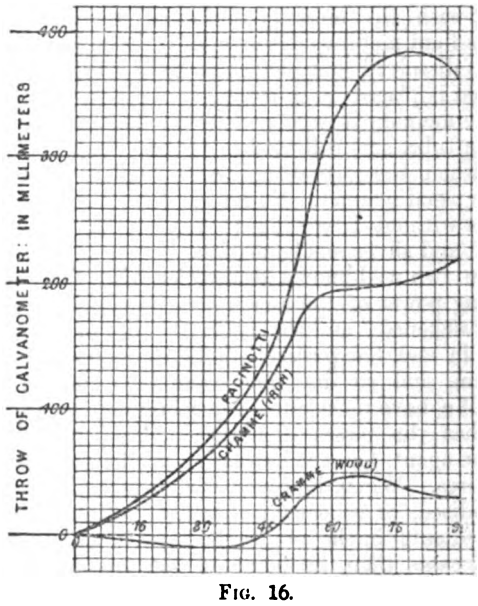

FIG. 16.

Breguet suggested as a reason the influence of the actual current circulating round the armature coils, which would tend to produce in the iron of the armature a magnetisation at right angles to that due to the field-magnets.

Breguet showed that there would be a resultant oblique direction of the lines of magnetisation in the field, and therefore, since the "diameter of commutation" is at right-angles to this direction, the brushes also must be displaced through an equal angle. Clausius accepts this view in his recent theory, and adopts for the angle of the resultant field that whose tangent is the ratio of the two magnetising forces due to the field-magnets and the current in the armature respectively. Professors Ayrton and Perry have also pointed out that there will be an additional displacement of the resultant pole of the armature, consequent upon the self-induction going on in the armature coil between its different sections. In their paper on the government of motors, in which they have brought out this point, they, however, take the view that part of the displacement of the pole is due to the sluggishness of demagnetisation of the iron. I do not think, however, that this can be maintained. No experimental proof has ever been given that there is any such thing as a true magnetic lag; the apparent

* Paper read before the Society of Arts, Feb. 28, 1884.

Digitized by Google

magnetic sluggishness of thick masses of iron is demonstrably due to internal induced currents; and no one uses solid iron in armature cores for this very reason. Neither has it been shown that thin iron plates or wires, such as are used in armature cores, are slower in demagnetising than magnetising. Indeed, the reverse is probably true; and, until further experimental evidence is forthcoming, I shall assume that there is no magnetic lag in properly laminated iron cores.

It may here be pointed out that, assuming as a first approximation that the rule that the tangent of the angle of lead represents the ratio between the magnetising power of the field-magnets and of the armature coils, the lead may be diminished to a very small quantity by increasing the relative power of the field-magnets, a course which is for many other reasons advisable. All practice confirms the rule that the magnetic moment of the field-magnets ought to be very great as compared with that of the armature. Further than this, there ought to be so much iron in the armature as to be just saturated when the dynamo is working at its greatest activity. If there is less than this, it will become saturated at a certain point, and when any currents greater than this are employed, the lead will alter, for then the magnetic effect due to the current in the armature will be of greater importance relatively to that due to the field-magnets. For the same reason, the lead will be more constant when the field-magnets are under their saturation point than when quite saturated. In short, every cause that tends to reduce the lead makes the lead more constant, and therefore tends to reduce sparking at the brushes. And the best means to secure this is obviously to use an unstinted quantity of iron—and that of the softest kind—both in the field-magnets and in the armature, for then the currents circulating in the armature will have less chance of perturbing the field.

In relation to the magnetisation of field-magnets, it may be pointed out that the "characteristic" curves, now so much used for the study of the action of dynamo machines, which show the rise of the electromotive force of the machine in relation to the corresponding strength of the current, are sometimes assumed, though not quite rightly, to represent the rise of magnetisation of the field-magnets. Now, though the magnetisation of the magnet may attain to practical saturation, it does not, under a still more powerful current, show a magnetisation less than saturation. But the characteristics of nearly all series-wound dynamos show—at least, for high speeds—a decided tendency to turn down after attaining a maximum; and for some machines, for example the Brush, this diminution of the electromotive force is very marked. The electromotive force diminishes, but the magnetism of the field-magnets does not. An explanation of this dip in the characteristic has lately been put forward by Dr. Hopkinson, in his lecture on "Electric Lighting," before the Institution of Civil Engineers, attributing this to the reaction of self-induction and mutual induction between the sections of the armature. No doubt this cause contributes to the effect, as all such reactions diminish the effective electromotive force. I am inclined, however, to think that the greater part of the effect is due to the shifting of the effective line of the field in consequence of the iron of the field-magnets becoming saturated before the armature is so. It is at least significant that in the Brush machine, where the reduction of electromotive force is very great, there is also such a mass of iron in the armature, and so variable a lead at the brushes.

Another point in which theory has for long been ahead of practice is in the advantage to be gained by working as nearly as possible with closed magnetic circuits; that is to say, with a nearly continuous circuit of iron to conduct the lines of magnetic force round into themselves in closed curves. The enormous importance of this was pointed out so far back as 1878 by Lord Elphinstone and Mr. C. W. Vincent, whose dynamo embodies their idea. Every electrician knows that if a current of electricity has to pass through a circuit, part of which consists of copper and part of liquids—such as the acid in a battery, or the solution in an electrolytic cell—the resistance of the liquid is, as a rule, much more serious than the resistance of the copper. Even with dilute sulphuric acid the resistance to the flow of the current by a thin stratum is 200,000 times as great as would be offered by an equally thick stratum of copper. And in the analogous case of using a field-magnet to magnetise the iron core of an armature, the stratum of air—or, it may be, of copper wire—in between the two pieces of iron, offers what we may term a relatively enormous resistance to the magnetic induction. If we take the magnetic permeability of iron as 1, then the permeability of air is something like 1-20,000th, and that of copper is not very different. Or, in other words, a stratum of air or copper offers about 20,000 times as much resistance to the magnetic induction as if the space were filled up with soft iron. Obviously, then, it would be a gain to diminish as much as possible the gaps between the portions of iron in the circuit. The values of the magnetic permeability for iron, air, and copper have been known for years, yet this simple deduction from theory has been set at defiance in the vast majority of cases. We have had, a few minutes ago, an experimental proof that the Pacinotti ring, so far from having been "perfected" or "improved" by Gramme, as some very high authorities say, is vastly inferior to it. It will, perhaps, be intelligible now why Pacinotti's design was essentially right.

I now pass on to the progress recently made in the practical construction of dynamo-electric machines. Thanks to the kindness of several of those by whom this progress has been achieved, I am able to put before you their very latest results.

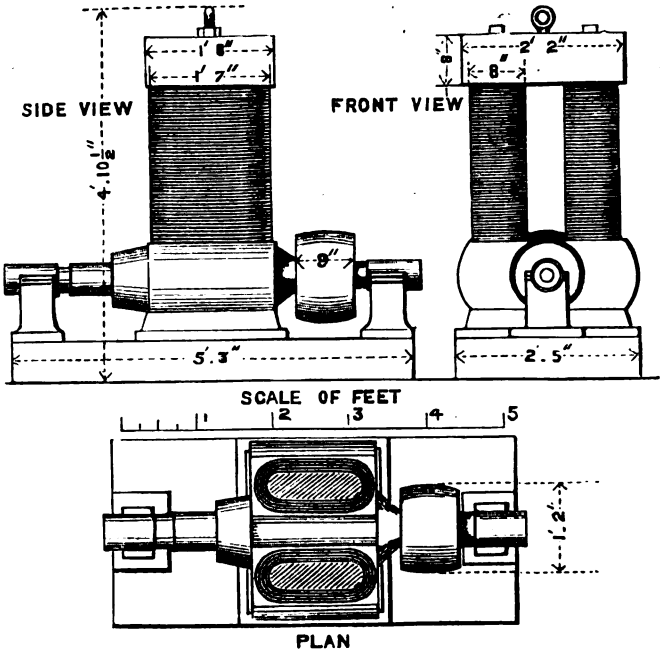

FIG. 17.—Edison-Hopkinson Dynamo.

The Edison dynamo has, during the past eighteen months, received very material improvements at the hands of Dr. Hopkinson, F.R.S. Some of these improvements relate to the field-magnet, others to the armature. Dr. Hopkinson has, in the first place, abolished the use of the multiple field-magnets, which in the Edison "L" "K" and "E" machines were united to common pole-pieces, and instead of using two, three, or more round pillars of iron, each separately wound, he puts an equal mass of iron into one single solid piece of much greater area of cross-section and somewhat shorter length. One such iron mass, usually oval or oblong cross-section, is attached solidly to each pole-piece, and the two are united at the top by a still heavier yoke of iron. The machines have, consequently, a more squat and compact appearance than before (Fig. 17). It may be remarked, in passing, that the use of multiple pillars of iron used by Edison in the "L," "K" and "E" machines must have been prejudicial, because the currents in those portions of the coils which passed between two adjacent iron pillars must have been opposing each other's magnetising effect. Dr. Hopkinson has also introduced the improvement of winding the magnets with a copper wire of square section, wrapped in insulated tape. This wire packs

Digitized by Google

more closely round the iron cores than an ordinary round wire. In the armature the following change has been made:—The iron core in the older Edison machines was made of thin iron discs, separated by paper slipped on over a sleeve of *lignum vitæ*; and held together by six longitudinal bolts passing through holes in the core-plates, and secured by nuts to end plates. These bolts are now removed, and the plates are held together by great washers, running upon screws cut on the axle of the armature. The size of the central hole in the plates has been diminished, thus getting into the interior more iron, and providing a greater cross-section for the magnetic induction. By these improvements a machine occupying the same ground space, and of about the same weight as one of the older "L" 150-light machines, is able to supply 250 lights, the efficiency being at the same time improved. In the new 250-light machine the diameter of the armature is 10 inches; its resistance, cold, is 0·02 ohm; that of the magnet is 17 ohms. The characteristic curve of the machine shows that even when doing full duty the field-magnets are far from being saturated. It will be remarked that, in the older construction, the bolts and their attached end-plates furnished a circuit in which idle currents were constantly running wastefully round, with consequent heating and loss. An Edison 60-light "Z" machine of

Fig. 18.

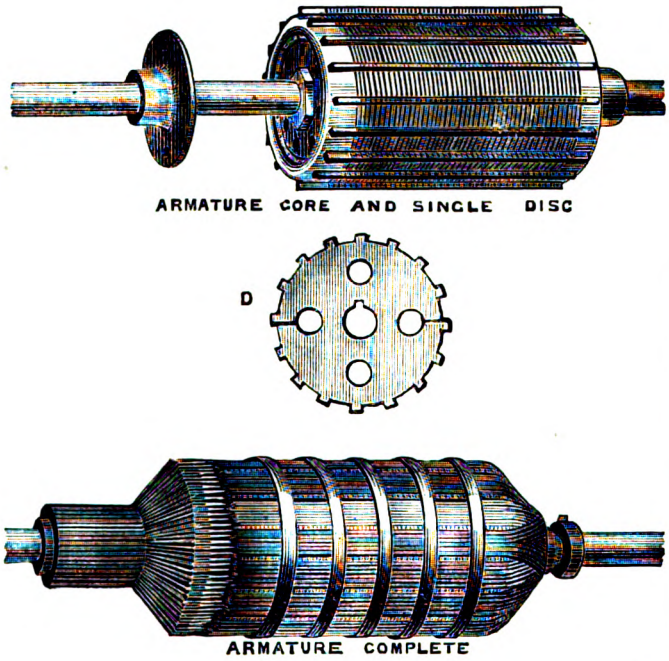

Fig. 19.

the older pattern, tested by the committee of the Munich Exhibition, was found to give an efficiency which, if measured by the ratio of external electric work to total electric work, exceeded 87 per cent.; but its commercial efficiency—the ratio of external electric work to the machanical energy imparted at the belt—was only, at the most, 58·7 per cent. In a recent test made by Mr. Sprague, at Manchester, on an improved dynamo (a 200-light machine), the efficiency of electrical conversion exceeded 95 per cent., and the commercial efficiency 85 per cent.*

The Edison Company states that "the weight and cost of the machines per lamp are greatly reduced," but they add a table from which it appears that the old 250-light machine costs £250, whilst the new 250-light machine costs £265, if made as a fast-speed machine, and £425 if constructed as a slow-speed machine.

The Siemens machines have not been much altered during the past year; and it is a little difficult to describe the improvements which have been made, as the firm of Siemens Brothers decline, for commercial reasons, to furnish data for publication. Progress has, however, been made by this firm, especially with their compound-wound machines, of which some account has been given by Herr E. Richter, in the *Elektrotechnische Zeitschrift*. It appears that three methods of combination have been tried. The shunt and series coils have been wound on different arms of the magnets; they have been wound on separate short frames, and slipped on to the cores side by side; and they have been also wound over one another. In the latest machines, the series coils are wound outside the shunt windings. The regulation, judging by the curves given by Herr Richter, is not perfect. The best regulation was from a "*g* D 17" machine, of which two of the magnet limbs were wound with shunt coils of 29 layers of a 1 millimetre wire, and the other two with two layers of a 3·5 millimetre wire. The potential varied from 64 to 69 volts when the number of lamps was reduced from 20 to 9.

The Weston machine has an armature more or less resembling those of the Siemens machines. The core is built up of discs of iron, of the form shown in Fig. 18, strung together, and presenting projecting teeth all along the surface of the cylinder. Fig. 19 shows the armature when completed. In this machine, as is also evident from Fig. 20, the pole-pieces are laminated, to obviate eddy currents and heating. Recently, Mr. Weston has adopted a method of winding the armature with two circuits, so that an accident to one section shall not completely break down the machine. The latest of the Weston machines show substantial design, and many improvements in detail upon the older forms.

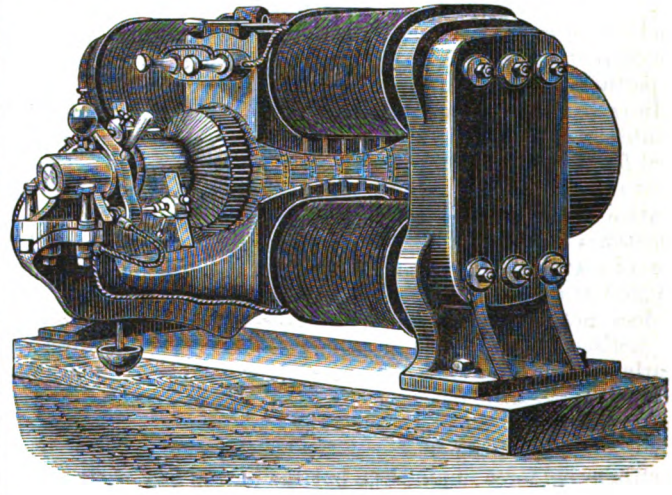

Fig. 20.—The Weston Dynamo Machine.

The machines of the Gramme type next come in for consideration. In those of the actual Gramme pattern I cannot learn that any important improvement has been made in this country; but in the States, the Fuller Electrical Company, which holds the Gramme and Wood patents, has brought out several improved forms of machine, in which mechanical engineering skill of a high order is apparent. The field-magnets, frames, and pole-pieces are very substantial, the ring is better built than the European types, and the collector bars are prevented from flying to pieces by the addition of an insulated ring shrunk on over their ends. In France, too, the machine has received important modifications at the hands of M. Marcel Deprez. M. Deprez's dynamo has two Gramme rings upon one axle, which lies between the poles of two opposing field-magnets, each of the two-branched, or so-called horseshoe form. These are laid horizontally, so that the north pole of one is opposite the south pole of the other, and *vice versâ*, the poles being provided with curved pole-pieces between which the rings revolve. M. Deprez, who has given much attention to the question how to design a machine which, with the least expenditure of electric energy gives the greatest actual couple at the axle, is of opinion that the horseshoe form of electro-magnet is the most advantageous. The iron cores and yokes of the field-magnets are very substantial; but the pole-pieces are not very heavy. M. Deprez's machine has a very elaborate system of sectional windings of the field-magnets and a switch-

* These values assume the B. A. unit as the true ohm, and are therefore probably about 1½ per cent. too high.

Digitized by Google

board, enabling him to couple up the connections in various ways. The circuits of the two rings are quite distinct, and each armature has its own collector and brushes. M. Deprez has also constructed other Gramme machines, with armatures of very fine wire, for his experiments on the electric transmission of power.

Another machine, having as an armature an elongated ring somewhat like that of the Maxim dynamo, was shown during last autumn at the Fisheries Exhibition, under the name of the Hochhausen dynamo. The field-magnets of this machine are very strangely disposed, the ring being placed between two straight electro-magnets placed vertically over one another; the upper magnet being held in its place by curved flanking-pieces of iron, which run down the two sides of the machine, and connect the topmost point of the upper magnet with the lowest part of the lower. This arrangement, which strikes the eye as being both mechanically and magnetically bad, is claimed as one of the virtues of the machine, which, in spite of its magnets, appears to be a very good working machine. Its armature is constructed of four separate curved iron frames, upon which the previously wound coils are slipped, and which are then bolted together and secured to

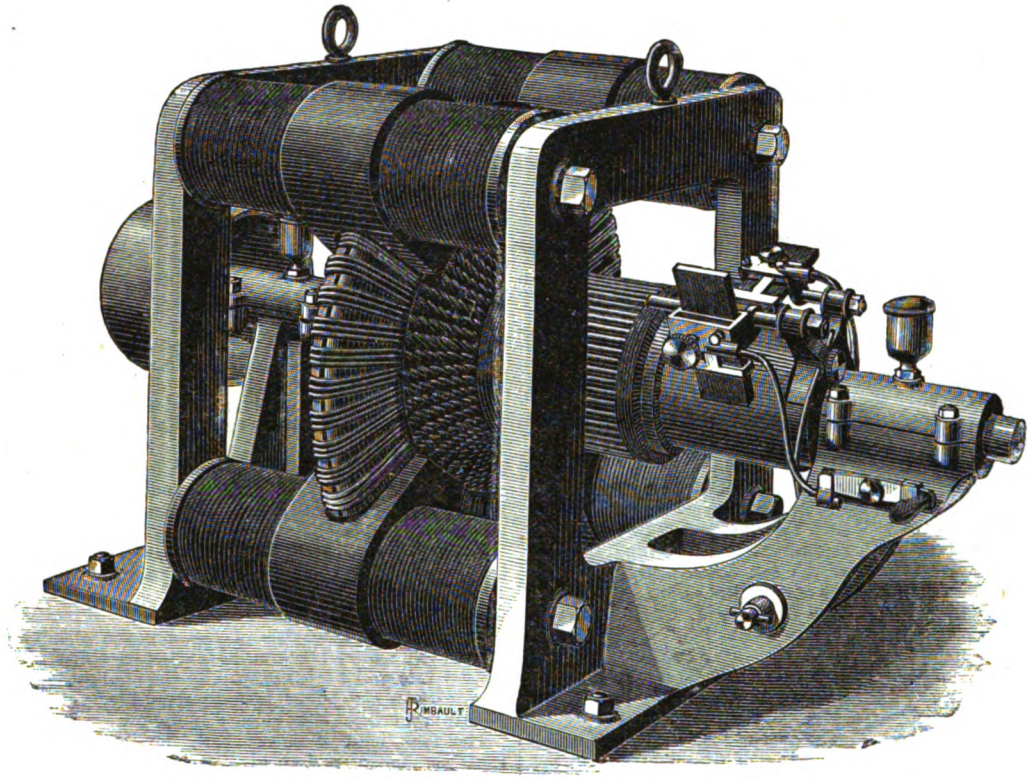

FIG. 21.—Victoria (Schuckert-Mordey) Dynamo (4-pole).

strong end-plates. I have not seen any report on the efficiency of this machine.

We next come to the class of machines in which a flattened Gramme ring is used, and of which the machines of Fein, Schuckert, and Gülcher are the best known types.

Mr. Gülcher has been steadily at work improving his dynamo in its various mechanical and electrical details. In particular, he has devoted attention to the winding of the field magnets, so as to secure a constant potential at the terminals. After experimenting with various methods of compounding, he finds that the best results are arrived at in the following way :—In his 4-pole dynamo there are eight cores to be wound. Each of these receives a shunt coil of fine wire, and outside this a main coil of stout wire. The eight fine wire coils are then joined up in series with one another, and connected as a shunt to the terminals; whilst the eight main circuit coils are joined up in parallel. In proof of the degree of accuracy attained by this method, Mr. Gülcher has given me many numerical data from actual tests. All of them show a very fair approximation to a constant potential, and an actually attained constancy for a considerable range. For example, a 4-pole machine, intended to give 65 volts, gave that figure exactly, when the external current varied from 30 to 88 amperes; and gave 64 volts at 105 amperes, 63·5 volts at 130 amperes. With one ampere only, the potential was 61·5 volts. Mr. Gülcher adds that, in spite of all possible care in manufacture, very large machines do not give results as satisfactory as those given by machines of somewhat smaller dimensions, though the machines are of identical type, and their parts calculated from the same formulæ. He thinks this, to indicate that to obtain the same ratio of out-put and efficiency to weight, there ought to be a corresponding increase made in the electromotive force of the machine. In other words, the means taken in large machines to keep down the electromotive force to equality with that of the smaller machines are detrimental to the action of the machine.

The Anglo-American Electric Light Corporation has been manufacturing during the past year a dynamo of the flat-ring type, under the patents of Schuckert and Mordey, to which the not very apt name of the "Victoria" dynamo has been given. By the kindness of Mr. F. Wynne, general manager of the Corporation, and of Mr. Mordey, and Mr. P. Sellon, I have been able to learn a great deal about this machine, and to test personally its capabilities. There are two types of the new Schuckert-Mordey dynamo, one having 4, the other 8 poles arranged round the ring. As mentioned earlier in this paper, Mr. Mordey has given great attention to the form of the pole-pieces. These pole-pieces, in the earlier Schuckert machines, consisted of hollow iron shoes or cases which occupied a large angular breadth along the circumference of the ring. Similar hollow polar extensions are still used in the Gülcher machines (see Fig. 26 of my Cantor Lectures). Mr. Mordey has found my opinion, based upon the diagrams of potential at the collector, to be correct, that these wide-embracing pole-pieces were responsible for false inductions, giving rise to opposing electromotive forces and setting up secondary neutral points at the collectors. He has, therefore, by long extended experiments, arrived at a form of pole-piece which completely obviates these effects. As will be seen from Fig. 21, which represents the 4-pole Victoria dynamo, the pole-pieces, though they embrace the ring through its whole depth, from external to internal periphery, are quite narrow, and do not cover more than 30° of angular breadth of the circumference of the arma-

Digitized by Google

ture. They are of cast iron, and are cast upon the cylindrical cores of soft wrought iron which receive the coils. It may be mentioned that, in the 4-pole Gülcher machines, the wide box-like pole-pieces are also cast on wrought-iron cores. The armature of the Victoria dynamo resembles in its structure the Pacinotti rather than that of the Gramme type. Its core is built up of rings cut from sheet charcoal iron, and Mr. Mordey has taken special pains to ensure that there are no electric circuits made in the bolting together of these cores, each plate being both electrically and magnetically insulated from the adjacent plates. Eddy currents in the core are thus almost entirely obviated. This was far from being the case with some of the earlier machines, in which, as in the Edison machine until Dr. Hopkinson improved it, the bolts holding together the cores constituted an available path for wasteful inductions. The core rings of the Victoria dynamo are toothed, as in the Pacinotti ring, and the wires are wound in the intervening gaps. There is, moreover, ample ventilation in this armature, a point not to be overlooked.

(TO BE CONTINUED.)

## THE SOCIETY OF TELEGRAPH ENGINEERS AND OF ELECTRICIANS.

### INAUGURAL ADDRESS.

Delivered by Professor W. GRYLLS ADAMS, F.R.S., 10th Jan., 1884.

I will not occupy your time in speaking of myself or of my own feelings, nor will I attempt to discover on what grounds you have conferred on me the great honour of selecting me as your president; but I trust that our society will advance no less rapidly than it has done in the past, and that it will continue to lead the way in electrical science.

I propose to draw your attention this evening to the rapid growth of electrical science, and to those principles of the science of energy of which dynamic electricity now forms a part. In tracing the history of the science of electricity, one cannot but be struck with the number of distinguished men who within the period of one hundred years have devoted themselves to its development.

About the middle of the last century, the discovery of the first accumulator of electricity by Cuneus, and the experiments and theory of Franklin, drew the attention of the scientific world to the phenomena of electricity, and induced men like Æpinus and Cavendish, and after them the Earl of Stanhope and Coulomb, to apply their powerful intellects to the working out of the principles of statical electricity. They were men who were capable of treating the subject both experimentally and mathematically—*i.e.*, of first making sure of their facts by testing them experimentally, with apparatus often of their own construction, and then of working out by mathematical treatment the full consequences of those facts, and gathering them up into the laws of electrical action. From that most interesting volume edited by the late Professor J. Clerk Maxwell, "The Electrical Researches of the Hon. Henry Cavendish," we are able to see exactly the point to which the science of electricity had been pushed by him just one hundred years ago, and we find that he was a man who had stepped far beyond the men of his time, and whose work remained quite unknown to those who came after him.

The idea of electrical potential was clearly present to the mind of Cavendish. He defines what he calls the "degree of electrification" as the compression—*i.e.*, *pressure*—of the electric fluid. He compares the ratios of the charges of bodies to that of a sphere, and speaks of a body as capable of holding so many "inches of electricity"—*i.e.*, a body whose capacity is equal to that of a sphere whose diameter is that number of inches. In fact Cavendish took a sphere of *diameter* 1 for his unit of capacity, whereas we now take a sphere for our unit whose *radius* is unity.

In estimating capacities he employed the method which recently Weber and Kohlrausch have employed to determine the ratio of electrical units. He proved that there is no free electricity in the interior of a closed conductor (the globe and two hemispheres), and proves from this that the electric force varies inversely as the square of the distance. He also compared and measured the numerical value of the specific inductive capacities of different substances.

In the absence of galvanometers, Cavendish compared the resistances of iron wire and salt water by making his body and the iron wire the branches of a divided circuit, and discharging a condenser through them; he then replaced the iron wire by such a length of salt water as would make the shock appear to be of the same strength. From this he concluded, rightly, that the resistances of the iron wire and salt water were equal. The accuracy of Cavendish's results was remarkable, for his results agree with the resistances of these substances found by our present methods at a temperature of 11° C. Taking himself for the galvanometer, he employed the method adopted by Professor Barker and Mr. Crookes, at the Paris Exhibition, to determine the electromotive forces in their tests of incandescent lamps. As they knew the value of the shunts, they could determine their electromotive forces, whereas he employed the method to get the value of his shunt, or rather to find when two shunts were equal.

Cavendish's electrometer consisted either of a pair of straws with cork balls on their ends, or a pair of pith balls suspended by silk strings from a glass rod, and yet with these he was able to compare the capacities of insulated conductors. His experimental determinations of the capacities of long narrow cylinders have been compared by J. Clerk Maxwell with their capacities as calculated by himself, with the following results:—

| | Cavendish. | Maxwell. |
|---|---|---|
| Capacities ..... | 5·669 ..... | 5·668 |
| ,, ..... | 5·754 ..... | 5·775 |
| ,, ..... | 6·044 ..... | 5·907 |

While Cavendish was working in England, Coulomb, in France, was investigating, by means of his delicate torsion electrometer, the laws of electrical attraction and repulsion; he also investigated, both experimentally and mathematically, the laws of distribution of electricity and of loss of charge from conductors, and his results were given to the world about 1785, after Cavendish's work was done. Coulomb's torsion balance was almost the only electrometer for accurate determinations until the electrometers of our own time, invented by Sir W. Thomson. After the times of Cavendish and Coulomb there was a lull in the pursuit of electricity, and the attention of the scientific world was drawn more especially towards the study of chemistry, which advanced rapidly toward the end of the last century, until in the year 1800 the uniting of these two sciences by Volta gave rise to the further development of electrical science in the form of voltaic electricity, and led the way to the grand discoveries of Davy, and of Faraday, and of Daniell on the relation of chemical action to electric currents.

I cannot stay to dwell on the early days of magnetism—the days of Gilbert and of Halley—nor need I do so, since one of my predecessors, Sir Wm. Thomson, has given us some account of the early progress of terrestrial magnetism, but would again point out that it was by the uniting of the two sciences of magnetism and of current electricity in the year 1819 or 1820 that Œrsted paved the way to the very rapid spread of electrical science, when almost each succeeding year gave birth to some new group of facts or some new instrument, or saw some new step taken which was important enough to be regarded as a new principle. Thus from 1820 we have Ampère's theory of magnets and of terrestrial magnetism, his laws of the action of currents on magnets, and on the mutual attraction and repulsion of currents; also the magnetic action of solenoids. We have also the invention of the multiplier, or galvanometer, and improved forms of this useful instrument, and the discovery of the first principles of electro-magnetism, all crowding on one another. The eleven-year period, from 1820 to 1831, not only embraced all these discoveries, but gave us also the laws of Ohm, and the work of Faraday on the induction of electric currents and on the evolution of electricity from magnetism, laying the foundations of the subject of magneto-electricity. As regards the growth of new principles, probably no period of eleven years has seen the science advance with such rapid strides.

These principles having been established, a new era in the history of the science begins with the methods of absolute measurement adopted by Gauss in 1832, in which he showed how the intensity of the earth's magnetic force and the magnetic moment of a magnet could be measured, so taking the earth's force as the standard of comparison for the measurement of magnetic forces; and this was soon extended by Weber to electric currents.

I will not dwell further on this branch of my subject, as it has already been treated by another of my predecessors in this chair.

In looking back over the history of a science, it is important to take into account the order in which scientific discoveries have been made. Since the earlier researches of Faraday, the labours of Joule, of Clausius, of Maxwell, and of Thomson have given us a new science, and have shown us that it is probably universal in its application, and that all the physical sciences may be regarded as linked together and as forming branches of this new science—the science of energy.

Had the science of energy been developed before Faraday's investigations were made, we shall hardly be wrong in conjecturing that his master-mind would have arrived at the conclusion which has been since established by Helmholtz and by Thomson, that the phenomena and the laws of induction currents are but deductions from the applications of the laws of energy to the discoveries of Œrsted and Ampère.

In Œrsted's experiment on the motion of a magnet in the neighbourhood of a current in a conductor, the potential of the magnet with respect to the conductor is altered by its motion, and the energy communicated to the magnet depends upon the rate at which this potential changes.

This work done by the current, together with the work done in heating the circuit, must be equal to the work spent in keeping up the current in the circuit. If no work is so spent, *i.e.*, if there is no electromotive force, but only a conductor forming a complete circuit, then the motion of the magnet will generate a current in such a direction as to oppose the motion, whose energy will be spent in heating the conductor. Here, then, we have Faraday's induction current. Maxwell has shown us how both the induction of currents and the mechanical force between them depend upon their coefficients of mutual induction through the medium surrounding them, and that in estimating electrical energy a portion is spent outside the conductors on the medium through which the induction takes place.

The principles of energy tell us that the mechanical energy spent in carrying the conductor across the magnetic lines of force of the earth, or of a magnet, is equivalent to the electrical energy produced within and around the conductor by the induction current.

We see here that there is some distinct and intimate, but as yet mysterious relation between the sciences of motion, of magnetism, and of electricity, and we also see that in these simple experiments are involved the principles with which we are concerned in our consideration of electric motors. The accurate measurements of Joule, of Peltier, and of Thomson

Digitized by Google

have shown the definite relations which the sciences of motion, of electricity, and of magnetism bear to the science of heat. The labours of Maxwell, based on measurements of the velocity of light and of specific inductive capacities, have given us some clue to the relationship between electro-magnetism and the phenomena of radiant heat and light, which must be regarded as only different effects of the same form of energy.

In electrical science, then, as in the science of motion of masses, we have to do with the principles of energy, the first law of which, the principle of conservation of energy, tells us that *whenever work is performed by means of heat, an amount of heat disappears which is equivalent to the work performed, and whenever work is spent in inducing heat, the heat produced is equivalent to the work performed.* Applying this to magneto-electricity, Joule showed that heat may be created by working a magneto-electric machine, and that if the current is producing no other kind but thermal energy, the total quantity of heat is equivalent to the work spent in producing the current. To which Thomson has added, that when a current produced by heat is made to work an engine, the difference between the heat absorbed, and the heat given out is equivalent to the mechanical work done by the engine.

The advantages of exact observation and measurement, when a science has passed through its early stages are seen in the power it gives of making new discoveries, by determining precisely how much of the observed phenomena may be due to well-known causes, thereby showing how much still remains to be accounted for. Let me illustrate my meaning by an instance. A magnet suspended by a silk thread oscillates about its position of rest in the magnetic meridian, and is gradually brought to rest by the resistance of the air and the stiffness of the thread. But the effect of these causes being exactly known, it is found, as was first shown by M. Arago, that if a copper disc be brought near to the magnet it will come to rest much more quickly than when the copper is absent; hence, in order to damp the oscillations of a galvanometer needle and bring it quickly to rest, it may be surrounded with a mass of copper. From the investigations of Faraday we know that currents of electricity are set up in the copper by the motion of the magnet, and that these currents react upon the magnet and check its motion.

Now let us see how the exact investigations of Joule on the principles of energy clear up our ideas on these and similar phenomena. In consequence of the earth's magnetic action upon it, the oscillating magnet has a certain amount of energy of position when it is at the extremity of its swing, which is transformed into energy of motion as it swings across the magnetic meridan in which it is suspended. Part of this energy is spent in overcoming the energy of torsion of the suspending fibre, in consequence of which the swings are diminished in extent. Another part is spent in communicating energy to the air by friction and by producing eddies in it. Another portion is spent in producing electric currents in the copper damper. The energy so spent may be determined experimentally by vibrating the needle of a galvanometer first without, and then with the copper damper.

(TO BE CONTINUED.)

## DIRECT SPANISH TELEGRAPH COMPANY (LIMITED).

The twenty-first ordinary general meeting of this Company was held on Thursday, at the offices, Leadenhall-buildings, 101, Leadenhall-street, Mr. Neil Bannatyne in the chair.

Mr. C. GERHARDI (the manager) read the notice convening the meeting, and the report of the directors was taken as read.

The CHAIRMAN thought that the report and accounts gave the shareholders so full a statement as to the position of the Company that it would not be necessary that he should add much more than a few remarks before proposing the first resolution. As regarded expenditure, it would be seen that, as compared with the previous half year, although there was a slight increase in some items in the working expenses for the half year ending 31st December, 1883, there was a considerable decrease in several others, showing a total decrease in the working expenses, as compared with the previous half year, of £93. They had been very unfortunate for some time past in regard to the frequent interruptions of their cable. As regarded the most recent interruption, the ship employed for the repairs had already repaired one break, and was on the point of repairing another. With reference to the new cable, for which the shareholders were aware they had contracted, the cable was nearly completed, only about fifty miles more having to be constructed, and it was confidently expected that the contractors would complete the laying of the cable in the early part of May, when it would at once be opened for traffic, and would, it was hoped, put an end to the constant interruption of communication so detrimental to the interests of the Company. The types of the various portions of the cable were such as their past experience had found to be suitable for the bottom on which the new cable would be. The course to be followed by the new cable had also been sounded with great care, and specimens of the cable were there for the inspection of the shareholders. The debentures for the new cable had been issued to the contractors so far as was required for their indebtedness to them. The total price of the new cable would be as nearly as possible £65,000. In consequence of the change of Ministry in Spain there had been some delay in obtaining their remittance of the balance due to them on telegraph account, but there was every reason to believe that this would be again regularly paid, and if so the balance for the fourth quarter of 1883 might be expected to reach them at the beginning of May, when the dividend warrants would at once be issued. He had only to add that they of course regretted very much that they had from time to time for some time past been unable to recommend a dividend on the ordinary shares of the Company. This was a result which they all very much regretted, but which it had not been in their power to prevent. He might say for himself that, as regarded their prospects, he was quite sure, from looking at their traffic returns from the opening of the undertaking to the present time, and seeing that the returns showed a gradual and steady increase from year to year in their traffic receipts, he had the greatest confidence when once they got the new cable into operation they would start on a course of greater prosperity than they had hitherto been able to enjoy. Such a result had been hitherto prevented by the enormous costs to which they had been put from time to time in repairing their cable, and the only matter of congratulation connected with this unfortunate result in time past was this, that had it not been for their arrangement and working agreement with the Eastern Company they would have been in a much worse position. That arrangement, of course, continued in full force, and he had no doubt that the Eastern Company desired to promote the prosperity of this undertaking by all means in their power, and he was sure that the arrangement they had entered into would work even more advantageously in the future than it had done in the past. He moved the adoption of the report and accounts.

Mr. ETLINGER seconded the motion.

Mr. DYETT asked if it was not proposed to issue any of the debentures to the shareholders?

The CHAIRMAN replied that within a very small amount of the whole of the debentures would be required to pay the contractors. At the last meeting one gentleman told them that they would not be able to get £60,000 in 6 per cent debentures, but he said he had no doubt that they would be able to do so, and the contractors had accepted them freely.

Mr. DYETT thought the debentures ought, in the first instance, to have been offered to the shareholders. He was aware of the remarks of one shareholder at the last meeting, but so far as he was concerned he should have been very glad to take some at 6 per cent. He supposed the contractors would put the debentures on the market.

The CHAIRMAN replied that the contractors might do what they liked with them, and if they chose to offer them to the public they could do so. The universal opinion, however, was when the plan of meeting the cost of the new cable was first mentioned that they would be very fortunate if they could get the contractors to take the whole of the money in 6 per cent. debentures. The directors were obliged to find the money, and could not go to the contractors and say they would give them what they could in cash, and so much in debentures.

MR. DYETT: Why not?

The CHAIRMAN: Because we could not depend on the debentures being taken up.

Mr. DYETT thought the shareholders ought to have been consulted in the matter.

The CHAIRMAN said that if they had issued debentures at 7 or 8 per cent. no doubt a fair portion would have been taken up by the shareholders. By the arrangement they had entered into they made the laying of the new cable a certainty, and that was what they wanted more than anything else, as they believed that that would put them in a position to pay a fair dividend to the ordinary shareholders. His own conviction was that before long they would be in a position to pay a moderate dividend to the ordinary shareholders. As to the dividend on the preference shares, that was beyond all question. There was no doubt they would always be in receipt of an ample balance to meet not only the debenture interest, but the dividend on the 10 per cent. preference shares. If their cable were in full operation, without being very sanguine they might take the gross receipts at £24,000 a year. Their working expenses were about £6,000 a year, 6 per cent. per annum on £65,000 was £4,000, the preference dividend took £6,000, so that there would be £8,000 left for the ordinary shareholders, and if they put by £2,000 or £3,000 to reserve, there would still be £5,000 or £6,000 left.

A SHAREHOLDER asked what would be done in reference to the breakages of the old cable?

The CHAIRMAN replied that that would be a question for consideration. If they got the new cable fairly at work they might consider the policy of spending more money on the old cable. They had an arrangement with the Eastern Company, so that if they had one new cable working efficiently, and a good cable in which they had confidence, and if they could go on for two or three years they would be in a much better position to spend a little money on the old cable if it were thought desirable that they should do so.

A SHAREHOLDER asked what period the working arrangement was for?

The CHAIRMAN replied for twenty years. He had omitted to give the traffic receipts for this year. For January they were £2,045, for February £1,567, and for March £1,905. Even though their cable had been down for some time, the result of their agreement with the Eastern was that they had had very fair receipts.

A SHAREHOLDER asked if shareholders who wished to do so could have some of the 6 per cent. debentures?

The CHAIRMAN replied that they would have to apply to the Telegraph Construction Company, who were the contractors for them. He could not bind them in any way, nor could he bind himself as to what that company would be inclined to do. He thought it very possible that if any gentleman took £1,000 to the Construction Company and said he wanted £1,000 of the 6 per cent. debentures they would accept it.

Mr. ETLINGER said that any application for debentures that came to their office could be forwarded to the contractors.

Sir JAMES ANDERSON said that they could not help the arrangement that had been entered into. If they had attempted to issue debentures, and they had not been taken up, the contractors would not have taken a thing that had been blown on. They got the cable they wanted; they got it very cheap, and it was for the Construction Company to deal with the debentures.

Mr. DYETT still thought that the debentures ought to have been offered

Digitized by Google

to the shareholders, and presumed that the directors had taken a certain quantity.

The CHAIRMAN: No, not one.

Sir JAMES ANDERSON: Not one.

The CHAIRMAN pointed out that the debentures of the West Coast of America Telegraph Company, which was now in a very flourishing condition, although they carried 8 per cent., were only at about 109. He thought that Eight per Cent. Debentures of the West Coast of America Telegraph Company at 109 were a vast deal cheaper than Six per Cent. Debentures of the Direct Spanish at par. He thought the hon. shareholder was under a complete delusion if he imagined that this Board could have got any amount worth mentioning issued at 6 per cent. to the public.

A SHAREHOLDER: The whole issue of the debentures was a portion of the scheme.
